BLACK'S GARDENING DICTIONARY

JOTTINGS OF AN ALLOTMENT GARDENER

A BOOK FOR ALL FOOD GROWERS

By E. T. ELLIS, F.R.H.S.

THIRD EDITION PRICE **1S. 6D.** NET

"This little book is full of hints to the allotment gardener—and most of them valuable anywhere in the country, although written mainly, perhaps, with a somewhat northern climate in view."
Journal of the Royal Horticultural Society.

". . . Contains not only a great deal of practical advice but gives 'the reason why for many operations.'"—*Farmers' Advocate.*

"A useful little book which does much to remove the troubles of the allotment gardener."—*The Scotsman.*

"The book is well indexed and the subjects it deals with are well classified. It contains most useful chapters on allotment questions generally, also on allotment associations and their value, schools and the land scheme, tables for showing crops, and gives the quantities of seeds required for plots of various sizes, etc."—*The Garden.*

1921

INDISPENSABLE BOOKS OF REFERENCE

WHO'S WHO.

An Annual Biographical Dictionary. Nearly 3000 pages.

Some Press Opinions.—"A National Institution."—"One is horrified to contemplate exist without 'Who's Who.'"—"Its non-appearance would be a public inconvenience."—"The one reference book that no one can afford to be without."

WHO *WAS* WHO, 1897–1916.

This volume contains the biographies taken from "WHO'S WHO" of those people who have died during the twenty years between 1897–1916. The date of death has been added in almost every instance.

TITLES: A Guide to the Right Use of British Titles and Honours.

With the multiplication of titles and honours that is continually going on, there are few who, at one time or another, are not in need of some such assistance to their right use as will be found in this volume.

THE WRITERS' AND ARTISTS' YEAR-BOOK, 1921.

Giving in compact form some 1000 addresses to which MSS. may be sent, and the kind of copy preferred.

From the Editor's Letter Bag.—"I find your Writers' Year-Book gives me just the information which I had long desired to possess, but which I was unable to obtain until a year ago, when the book was brought under my notice."

ATHENA: A Year-Book of the Learned World, 1920.

(The English-Speaking Races.) Edited by C. A. EALAND.

Up to the present there has not appeared any Guide to the Learned World printed in English. In pre-war days "MINERVA" was of service to those who could read German, but the publishers of "ATHENA" feel that the time is now propitious for the launching of a work of greater service to a larger number of people. Should this volume meet with the approval which is anticipated, it is the intention of the publishers to increase its scope in new editions.

BLACK'S DICTIONARY OF PICTURES.

A Guide to the best Work of the best Masters.

Edited by RANDALL DAVIES.

This volume contains descriptive accounts, with full and accurate particulars, of nearly a thousand of the most important pictures in public galleries in this country and on the Continent. They have been selected out of the immense number of exhibited works as being those which, in view of the opinions of the best critics, or in some cases by popular suffrage, are such as practically everybody who cares about pictures ought, or would like, to know something about.

BLACK'S MEDICAL DICTIONARY.

Sixth Edition, completing 45,000 copies, illustrated.

A very useful and cleverly written volume which, while carefully avoiding abstruse and intricate technicalities, affords information upon all important medical subjects in a form which places it within the comprehension of those who lack scientific training and scientific knowledge.

BLACK'S DOMESTIC DICTIONARY.

Edited by EDITH A. BROWNE, F.R.G.S., and MYRIAM ROTHSCHILD.

Black's "DOMESTIC DICTIONARY" is an entirely new work, up to date in every detail, compiled and written by those having first-hand knowledge of the conditions under which we are now living, and of the things necessary for managing a home on the right lines of economy and efficiency; it is thorough in all its features, taking up a subject from its foundation point to finish.

BLACK'S SIMPLE COOKERY AND HOUSEHOLD MANAGEMENT.

The recipes in this volume have all been prepared and tested from the point of view of economy, nourishing value and appetising character; but, in addition to the recipes, there are valuable hints on marketing and economies for small householders, which, if acted upon, should effect a saving in many homes.

BOOKS THAT COUNT.

A Dictionary of Standard Books.

CAREERS FOR OUR SONS.

A Practical Handbook to the Professions and Commercial Life.

PUBLISHED BY A. & C. BLACK LTD., 4, 5 & 6 SOHO SQUARE, LONDON, W. 1.

THIS BOOK IS DEDICATED

PREFACE

BLACK'S GARDENING DICTIONARY has been in active preparation for about three years, but the difficulties of production during the war and post-war periods have caused delay in its publication. Although every care has been taken to keep the large numbers of separate articles up to date during its progress through the press, it is just possible that something may have escaped the eye of the Editor, and this statement will explain anything of this nature that may be revealed. The aim of the book is to be useful, reliable, and practical for every amateur or professional gardener.

It has an adequate article on every matter of interest to the modern gardener. Every branch of the subject is dealt with by the best available experts, and no pains have been spared to give the gardening public the horticultural book of reference for which there has been a crying need for the last quarter of a century; it should become the standard work.

Our aim from the start has been to produce a book in as handy a form as possible, which shall be essentially modern, frankly popular, and above all USEFUL. There are plenty of good horticultural works dealing with the subject more or less from a botanical standpoint, and there is certainly no need to add to the number of such volumes. In BLACK'S GARDENING DICTIONARY botanical descriptions have been reduced to the minimum.

It was hoped, when the preparation of the work was first considered, that it would be found feasible to ignore botanical names to a very large extent, and to describe the majority of plants under their popular or English names. It was, however, found to be impossible to adopt this throughout on account of the large number of purely local popular names in existence. We have, however, described the culture of the Potato in an article on *POTATO* instead of under its botanical name Solanum, and where names of flowers are fixed and well known have generally adopted the same principle. Both popular and botanical names are generally given in the articles, and the large number of cross references will enable any plant or topic to be turned up in a moment or two.

As regards nomenclature, we have generally followed that of the *Kew Hand-lists* and *Index Kewensis*, but in some cases have departed from them for various reasons, chiefly on account of other names being in our opinion far more familiar to the general gardening public, including the nursery trade, and more suitable for general use. Where selections of varieties are given, these are usually modern sorts, though old favourites have by no means been entirely ignored. The best of the latest sorts are given under a heading " New Varieties " at the end of articles on the plants concerned. These have all been introduced since the beginning of the War.

We should be sorry indeed to let the work appear without a brief word of thanks to some of those who have given us special assistance in its pre-

paration. We are delighted to have contributions from so many Editors of horticultural and other publications, and desire specially to thank Mr. W. J. Chittenden, the Editor of *Garden Life,* who has made many practical suggestions in addition to contributing a large number of articles, and Mr. Walter Brett, the Editor of the *Smallholder, Smallowner, and Smallfarmer.* Special thanks are due to Mr. Edward White for the valuable contribution he has made on Garden Design on Modern Lines ; to Mr. J. L. Gibson, who has undertaken the notes on the chief Florists' Flowers ; to Mr. C. H. Curtis, Managing Editor of *The Gardeners' Chronicle,* for his notes on the chief Annuals ; to Mr. W. Irving, for describing the best Rock Plants ; to the Ministry of Agriculture and Fisheries, and to the Royal Horticultural Society.

It has not been thought well to neglect entirely the historical and literary aspects of horticulture, even in so popular a work as the present, since there is a growing interest in these subjects, especially among the more leisured of the gardening public. Brief historical notes on some of the old favourite flowers, and articles on Garden Lore and Literature of the Garden, are therefore included. Mr. C. Harman Payne has had charge of this part of the undertaking. The late Canon H. D. Rawnsley has written an interesting article on Garden Poetry.

Although no attempt has been made to make this work a dictionary of commercial horticulture, we have nevertheless thought it well to give short practical articles on Market Gardening and Weights and Measures—the latter containing unique "see at a glance" tables. Mr. John Weathers, the well-known author and editor, has done the first and a large part of the second article.

Mr. S. Arnott of Dumfries has undertaken the revision of the great majority of the notes on herbaceous perennials for outdoor work, and his careful scrutiny has prevented many little errors from creeping in. Mr. G. W. Turnbull, of Carnforth, has given the Editor the benefit of his knowledge in connection with chemical details in the articles on Ammonia and Ammonium Compounds, Lime Compounds, etc., and has read these for press.

The Editor's Secretary, Miss E. M. Knight, has tackled the vast correspondence which the work entailed, with a never-failing courage, and the Editor feels that a word of very hearty thanks is due to her.

Suggestions and corrections for inclusion in any future edition will be acknowledged promptly. They should be addressed to the Editor, Black's Gardening Dictionary, 4 Soho Square, London, W. 1.

November 1920.

BLACK'S
GARDENING DICTIONARY

NOTE.—Cross references to other articles are printed in italic caps. ; thus, *SHRUBS*.

ABELE (*Populus alba*). — See *TREES*.

ABELIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

ABIES.—For best species see *TREES*.

ABIETIA.—For best species see *TREES*.

ABRAXAS.—See MAGPIE MOTH in *INSECT PESTS*.

ABSINTHIUM.—Now included in the genus *ARTEMISIA*.

ABUTILON (Nat. Ord. Malvaceæ). These are evergreen shrubs of vigorous growth, branching freely. The branches are thickly covered with buds of bloom, which, when fully expanded, pass from bell-shaped to an almost open form about 3 ins. in diameter. They are of easy culture, thriving in a compost of light turfy loam, peat, and sand, and are invaluable for indoor decoration. They are propagated by cuttings of the young wood inserted in light soil in a close frame in autumn or spring. Temperature needed 40–50° F.

Greenhouse Species and Varieties.—*Abutilon Boule de Neige.*—Fine white. Flowers in August, September, October, and November. Height, 1½–2 ft.

A. Darwinii superbum.—Orange red. Flowers from April to August. Height, 1½–2 ft.

A. Diadem.—Deep purple. Flowers from August to November. Height, 1½–2 ft.

A. Golden Fleece.—Fine bright yellow. Flowers from August to November. Height, 1½–2 ft.

A. Red Gauntlet.—Reddish crimson. Flowers from August to November. Height, 1½–2 ft.

A. rosaeflorum.—Good rose. Flowers from August to September. Height, 1½–2 ft.

A. Thompsonii.—This is a favourite variety with ornamental foliage. Its leaves are green, mottled with yellow and cream-white. Useful for summer bedding. Height, 1–2 ft.—JNO. HL.

NEW VARIETY.

A. Triumph.—This is semi-double, and has large, soft pink, basin-shaped flowers.

See also *CLIMBING AND TRAILING PLANTS*, and *SHRUBS*.

ACACIA (MIMOSA. Nat. Ord. Leguminosæ). — This is a free flowering greenhouse shrub suitable for spring decorations. The genus includes many distinct shades of yellow, and the species are variable in habit and foliage. Cuttings of half-ripened wood taken at a joint in autumn root freely in sand and peat, if placed under a frame or hand-light with slight bottom heat. Pot firmly in good peat and sand.

Greenhouse Species.—*Acacia armata.*—Yellow. Flowers in May. Height, 1–2 ft.

A. dealbata (SILVER WHATTLE).—The Mimosa of Covent Garden Market, which is produced from seed and most valuable for cutting.

Yellow. Flowers in May. Height, 2–6 ft.

A. diffusa.—Yellow. Flowers in May. Height, 1–2 ft.

A. Drummondii.—Yellow. Flowers in April. Height, 1–2 ft.

A. grandis. — Golden - yellow. Flowers in March. Height, 1–2 ft.

A. longifolia.—Yellow. Flowers in May. Height, 1–2 ft.

A. Riceana.—Yellow. Flowers in May. Height, 1–2 ft.

ACAENA (New Zealand Burr. Nat. Ord. Rosaceæ).—This is a large genus of trailing plants, but we need only trouble with four of the dwarfer sorts which are suitable for the rock garden. These thrive in well-drained sandy soil, in a sunny position, and are propagated by division of the roots in autumn and spring. Seeds will, as a rule, germinate in gentle heat if sown in March.

Acaena adscendens.—This is a dwarf trailing perennial. Flowers purplish. Site open. Soil ordinary. Flowering Period, June to August. Height, about 6 ins.

A. Buchanani.—This is a dwarf trailing plant which is most valuable for carpeting purposes, with bluish-grey pinnate leaves. Flowers insignificant. Site sunny. Soil sandy. Height, 1–2 ins.

A. microphylla.—This is another useful dwarf trailer with bronzy pinnate leaves. Flowers crimson on spiny heads. Site sunny, in rock crevices or joints of paving stones. Soil light, sandy. Flowering Period, June to September. Height, 3 ins.

A. Novae Zelandiae.—This is also a trailing plant with bronzy pinnate leaves. Flowers bronzy on spiny heads. Site sunny. Soil sandy. Flowering Period, June to September. Height, 2 ins.—W. I.

ACAMPTOPAPPUS.—Now included in the genus *Aplopappus.*

ACANTHOLIMON (Prickly Thrift. Nat. Ord. Plumbaginaceæ).—These plants form dense tufts of evergreen spiny foliage. About eight species are in cultivation. All are rock plants, and do best in sunny well-drained positions or on rocky ledges. They are propagated by layering in summer, also by cuttings in July. We describe the four best below:—

Acantholimon acerosum.—Cushion-like tufts of stiff glaucous leaves with sharp points. Flowers rose-coloured in short racemes. Site warm, sunny, rocky crevices. Flowering Period, July. Height, 4 ins.

A. androsaceum.—Tufts of very short spiny glaucous leaves. Flowers crimson-purple. Site warm, sunny. Flowering Period, June to August. Height, 4 ins.

A. glumaceum.—Tufts of green spiny leaves, making large cushions. Flowers bright rose. Site warm. Soil, sandy loam. Flowering Period, June to August. Height, 6 ins.

A. venustum.— Leaves spiny, glaucous, in open rosettes. Flowers rose-pink on long spikes. Site sunny. Soil gritty. Flowering Period, June to August. Height, 6 ins.—W. I.

ACANTHUS (Bear's Breech. Nat. Ord. Acanthaceæ).—In this we have some useful ornamental leaved plants for the herbaceous border. The stove species are of little concern to us. The hardy sorts are not as largely grown as they might be.

Culture.—These plants are not difficult to grow provided an ordinary light soil is afforded, and so long as they are not planted in fully exposed or bitterly cold sites. A south border is probably the best position for them. They may be used in shrub borders or even in a warm wild garden. Planting may be done any time from November to late

March, and division of the roots may be done at the same period. They may also be propagated by seeds sown in the ordinary way in sandy soil.

What to Grow.—Omitting the stove species, we recommend the following for the outdoor garden:—

Acanthus Caroli-Alexandri.—A useful pale rose-pink sort blooming in August. Height about 18 ins.

A. hirsutus.—This is a rose or rose-pink species which appears to be at its best in late July and early August. It grows nearly a yard high.

A. hispanicus (Syn. *A. niger*).—A white species flowering in August and growing about 24 ins. high.

A. mollis.—This is probably the most widely grown and popular sort. It blooms in August and can be had in various colours such as pink, purple-pink, and white. Its average height is a little more than a yard.

A. spinosissimus.—By some regarded as a variety of the species described below, this is a white August blooming sort averaging about a yard high.

A. spinosus.—This sort can be had in white, pink, or purple-pink. It is not as widely grown as *Acanthus mollis*. It blooms in July and August, and averages about a yard in height. *A. s. spinosissimus* is a good variety.—E.

ACARNA.—Now included in the genus Atractylis.

ACCOUNTS: Garden and Allotment. A question very often asked, and one which is but seldom easy to answer, is found in "Does your Garden pay?" A definite reply is not often given if the question is put to private gardeners; they will probably say: "Oh yes, I think it pays, but I do not really mind if it does not." If, however, the question is put to a market grower, he answers "Yes" quickly enough, since if his garden did not pay he would soon be bankrupt.

We are much in favour of private gardens being financed much more in the manner of market gardens. In market gardening the keeping of strict accounts is essential to success, and it would be a much more satisfactory arrangement if accounts were strictly kept for private gardens as well. At present very little is done in this direction; in many cases money is no object, it is handed to the gardener for payments, and set down in the householder's account as "Gardening," but no attempt is made at finding out what the gain or return from this money is.

People we have spoken to on this question have said to us: "Why should we trouble? We get the pleasure and the vegetables out of our garden, and whether it pays or not does not matter." We think, however, it matters greatly.

We may say without fear of contradiction that many large gardens of country residences are conducted in a far too extravagant manner. Since there is no reckoning up of profit and loss, there is no way of determining exactly where this extravagance lies. No one can blame the head gardeners of such places. They want to give their master of the best; and until they know that he is reckoning up profit and loss and wants a fair return for the big bills he has to pay, they will continue in their old ways. But the moment he begins to wonder why the bills are so big and enters into the question, his head gardener will find that he can give him just the same for nearly half the cost.

On allotments more care should be taken still in the keeping of accurate detailed accounts. Even the first year, the holder should

be able to make his allotment pay,[1] and in subsequent years it will, with care, pay very highly indeed.

Method is everything in the keeping of allotment accounts. The gardener should buy a little account-book and keep the left-hand page for Expenditure, and the right-hand for Receipts. Thus his first page will probably read as follows :—

EXPENDITURE.[2]

Jan.		s.	d.
3.	Tools (spade, fork, and rake)	15	0
5.	Manure (1 load)	6	0
7.	Road sweepings (1 load)	2	0
10.	Lime (2 cwt.)	4	0
15.	Soot (1 bag)	0	0
24.	Manure (1 load)	6	0
		£1 13	6

His receipts will not begin until about June, when he will start pulling his peas and saladings, and lifting his early potatoes. He will not need to sell his produce to find out what his receipts are, but he should ask his wife to inquire on the day he lifts or gets in his crops what the current price is, and enter this in his book.

A page in his receipts in the summer will probably read something like this :—

RECEIPTS.[2]

June		s.	d.
3.	10 heads of lettuce at 1d. each	0	10
16.	1 peck peas	2	6
20.	1 peck broad beans	2	6
25.	20 heads of lettuce at 1d. each	1	8
29.	2 stone early potatoes at 2d. lb.	4	8
30.	Half-peck broad beans	1	3
		13	5

In the autumn, when he is getting up his crops, his receipt section will be very full. For instance, here is a page in October :—

RECEIPTS.[2]

Oct.		£	s.	d.
1.	2 cwt. maincrop potatoes at 5 lb. for 6d.	1	2	5
1.	Onions	0	10	0
8.	4 cabbages	0	0	8
8.	2 cwt. maincrop potatoes	1	2	5
10.	2 cauliflowers	0	0	6
15.	2 cwt. maincrop potatoes	1	2	5
		£3	18	5

These examples will be sufficient to show the method of working. The allotment-holder can find out which is the most paying crop by adapting the above method to his own circumstances; he can also find out which crops do not pay for the cost entailed in producing them, and thus avoid these.—E.

ACER.—For the best species see *Trees*.

ACERATES.—Now included in the genus Gomphocarpus.

ACHILLEA (Milfoil or Yarrow. Nat. Ord. Compositæ).—This genus contains a number of more or less useful herbaceous species, though we must confess there are many better things. The Achilleas are of spreading habit; they spread by numerous underground stems and shoots, so should not be planted near choice plants. They succeed in any good garden soil in a sunny position, and the white flowers of the Ptarmica variety, (known also as the Double Sneezewort by those who are fond of fantastic English names), form a very striking addition to the forepart of any herbaceous border. They are easily propagated by division of the roots in the autumn or spring, or by root cuttings. They can also be raised from seeds, as mentioned under the Rock Garden Species.

Perennial Border Species.—A few

[1] At the beginning of the food crisis in 1917 the writer took a 400 sq. yd. war plot with a view to finding out if it would pay the first year. A careful account was kept, and it was found at the end of the season that there was a clear profit of £2. The writer had not more spare time than other gardeners; indeed, much of his time was taken up in giving requested demonstrations of the best methods of working.

[2] All prices are 50–100 per cent. more at time of going to press owing to abnormal conditions.—Editor.

of the many are briefly described below :—

Achillea filipendulina.—A species producing bright yellow flowers from June to September. Height, 4 ft.

A. lingulata buglossis.—A fine form bearing white flowers in June and July. Height, 2 ft.

A. macrophylla.—A species with large leaves and white flowers. It blooms from midsummer to the end of July. Height, 3 ft.

A. Millefolium roseum.—A rose variety of the weed Milfoil, blooming freely in the summer. Height, about 2 ft. ; sometimes more.

A. Ptarmica flore pleno.—This is the variety most usually grown. Its masses of double-white flowers produced during the three summer months are good for cutting, or it can be used as a foil for other colours in the herbaceous border. It grows luxuriantly, but needs early staking. *Boule de Neige, The Pearl,* and *Perry's White* are specially good forms. Height, about 2 ft.

A. serrata.—A white species flowering from June to August. Height, 1–1½ ft.

A. Tournefortii.—A species bearing bright yellow flowers from June to August. Height, 2 ft.—E. T. E.

Rock Garden Species.—These number about a dozen. All the dwarf sorts are suitable, and thrive in well-drained sandy loam in a sunny position. To propagate, divide the roots in autumn or spring. Most species are also easily increased by seeds sown in gentle heat in March.

Achillea ageratifolia (Syn. *Anthemis Aizoon*).—Leaves in rosettes, silvery, with crimped margins. Flowers pure white, with yellow disc. Site sunny. Soil deep gritty. Flowering Period, June to August. Height, 6 ins.

A. argentea.—A tufted species. Foliage silvery and pinnate. Flowers white. Site sunny. Soil sandy. Flowering Period, July to September. Height, 6 ins.

A. Clavennae.—A neat tufted species. Foliage silvery, leaves lobed. Flowers white in heads. Site sunny. Soil gritty. Flowering Period, June to September. Height, 8 ins.

A. Griesbachii.—Similar to *A. argentea,* but of looser habit, and with larger blooms. Flowers white. Site sunny. Soil sandy. Flowering Period, June to September. Garden hybrid. Height, 8 ins.

A. Huteri.—Similar to *A. umbellata,* but taller. Flowers white. Site sunny. Soil sandy. Flowering Period, June to September. Garden hybrid. Height, 6 ins.

A. moschata.—A sort with subshrubby stems. Leaves pinnate, woolly. Flowers white in heads. Site rocky ledge or crevice. Flowering Period, June to August. Height, 6 ins.

A. rupestris.—A neat and tufted species. Foliage green and prostrate. Flowers pure white. Site sunny. Soil gritty, with leaf-soil. Flowering Period, May to August. Height, 4 ins.

A. tomentosa.—Leaves in rosettes green and pinnate. Flowers yellow. Site sunny. Soil sandy. Flowering Period, May to August. Height, 9 ins.

A. umbellata.—A dwarf, tufted species. Foliage silvery, with leaves lobed. Flowers pure white in loose heads. Site, rocky ledge or crevice. Flowering Period, June to September. Height, 4 ins.—W. I.

See also under YARROW in *MEDICINAL HERBS.*

ACHIMENES (Nat. Ord. Gesneraceæ). These form an important section, their lovely flowers giving a long succession of blooms, and they are most suitable for hanging baskets or pots. When they have finished flowering let them dry off and rest.

Repot the dry corms in February, placing several corms in a pot or basket, and give a little gentle heat to start them. Set them in light turfy loam, leaf-mould, and sand. Temperature needed, 45–55° F.

Greenhouse Species and Varieties. —*Achimenes Carl Woolfarth.*—Purplish-crimson. Flowers from June to September. Height, 1–1½ ft.

A. longiflora major.—Large blue. Flowers from June to September. Height, 1–1½ ft.

A. Marguerita.—Pure white. Flowers from June to September. Height, 1–1½ ft.

A. Pink Perfection.—Magenta rose. Flowers from June to September. Height, 1–1½ ft.

A. Scarlet Perfection.—Carmine scarlet. Flowers from June to September. Height, 1–1½ ft.

A. Unique.—Deep crimson, eyes yellow. Flowers from June to September. Height, 1–1½ ft.

ACID MANURES.—See under PHOSPHORUS in *CHEMISTRY FOR GARDENERS.*

ACID SODIUM SULPHATE. — See SODIUM HYDROGEN SULPHATE in *SODA AND SODIUM COMPOUNDS.*

ACIDIA.—See CELERY FLY in *INSECT PESTS.*

ACIDS, BASES, and SALTS.—See *CHEMISTRY FOR GARDENERS.*

ACIDS : Their Uses in Horticulture. Chemists tell us that there are many hundreds of acids now known, and that the number will increase to an unlimited extent if Chemistry continues to progress at its present rate. Despite the hundreds of acids that are now known, only a fraction of them are any use to the practical gardener, and the notes which follow include the most useful dozen. It may be mentioned that most of the better known organic acids, for instance humic acid, are purposely omitted, since they hardly are covered by the title of the present article.

CARBOLIC ACID is first of the twelve, if we consider them in alphabetical order. In Chemistry it is represented by C_6H_5OH. The chief value of carbolic acid to the gardener is the fact that it can be used very effectually as a soil fumigant. One part of the acid is best mixed with about 100 parts of water; and a gallon of the liquid sprayed on each square yard of vacant land in the early winter. The popular name of Carbolic Acid is PHENOL.

CARBONIC ACID (H_2CO_3) is a very weak acid but extraordinarily useful to the gardener indirectly. The pure acid cannot be obtained, since carbon dioxide (CO_2) is a gas. Spring water often contains it, and water from limestone districts may contain so much of it that lime is dissolved forming bicarbonate, and hence the water is temporarily "hard." It is produced by rotting manure of any kind, and what is known to gardeners as "soil water" is really a very weak solution of carbonic acid. This soil water has a great power over insoluble manures such as phosphates; it also has the power to break down clay and liberate its potash, so carbonic acid must be regarded as very useful to the gardener.

CITRIC ACID ($C_6H_8O_7+H_2O$). —The chief use of this acid to the gardener is to test the availability of phosphates for the food of plants. Many phosphates such as those in bones, coprolites, basic slag, guano, and patent manures, are what is known as "insoluble phosphates," namely, they will not dissolve in water at all. It has been found, however, that in some cases these phosphates will dissolve in quite a large quantity in a weak solution of citric acid, and it has been further found that a 2 per cent. solution of citric acid is equivalent in its dissolving power of phosphates to

ordinary soil water, which, as stated above, is really a very weak solution of carbonic acid. This gives us a means of estimating the value of our phosphatic manures, for the more soluble phosphate they contain the greater their value. The gardener prior to buying the manures just named should obtain small samples and test them with 2 per cent. citric acid solution. If after filtering off and weighing the residue he finds that none of it has dissolved, then the material is valueless as a phosphatic fertiliser. If, however, he finds that as much as a fifth or two-fifths (20 or 40 per cent.) has dissolved, the material is of considerable value and should be purchased.

HYDROCHLORIC ACID (HCl) is not much used by the gardener, though to the chemist it is one of the most useful. However, it can be used to test the amount of lime in any soil. To do this a fair sample of the soil (free from stones, roots, etc.) is put into a shallow pot. This is just covered with water, and over this is poured a small quantity of strong hydrochloric acid. If the material starts to fizz or effervesce very briskly and the gas produced extinguishes a lighted taper, then there is plenty of lime in the soil; if practically no effervescence takes place then lime should be added. The actual weight of lime present in any sample of soil can be estimated by using simple apparatus and weighing the acid and liquid before or after mixture. The difference will be the loss of gas given off. To every 44 parts of gas given off (by weight) add 56, and the total is the weight of limestone in the soil you weighed.[1] The popular name of this acid is SPIRITS OF SALTS.

[1] In other words, 44 parts of the gas given off are equivalent to 56 of quicklime.

HYDROCYANIC ACID (HCN).—This acid is sometimes used for fumigating, and is made by pouring sulphuric or hydrochloric acid on to cyanide of soda or potash. As, however, the fumes are so very dangerous to human life it is best left severely alone. Even when the greatest care is taken accidents may happen, and seeing there are so many equally good but less dangerous materials for fumigating no excuse can be made for using this one, which is popularly known as PRUSSIC ACID.

HYDROFLUORIC ACID.—This is another very dangerous acid. It is a compound of two gases, hydrogen and fluorine; its chemical symbol is HF. The only use it is from the gardener's point of view is its wonderful power for cleaning dirty glass. There are no stains or dirt marks on glass but what can be fetched off with the greatest ease with this acid. It has a violently solvent action upon glass and almost every form of pottery, so it has to be stored in rubber bottles. Rubber gloves should be put on, also glasses and a mask to protect the eyes and face. The acid should be rubbed over the glass with a square of india-rubber, and as soon as ever the dirt has been removed a quantity of cold water should be washed down it. Do not leave a bottle of it lying about. If you have purchased a little too much, dig a deep hole and bury it.

HYDROFLUOR-SILICIC ACID (H_2SiF_2) is similar to but less active than the above. It can be used for the same purpose.

NITRIC ACID.—This is a powerful and very dangerous compound in its pure state, yet leaf-plants depend on it and its compounds the nitrates more than almost any other compound in existence. Nitric acid is formed in small quantities by

flashes of lightning during thunderstorms, and is washed down to the roots of the plants. It can be used in a diluted state for dissolving bones—in a pure state it would char them. Nitric acid oxidises organic compounds in manure and breaks them up into simpler compounds. Its compounds are useful leaf-producing salts, but their application can easily be overdone. This acid is popularly known as AQUA FORTIS.

NITRO-PHOSPHORIC ACID.—Strictly this is not an acid at all, but a mixture of two—nitric and phosphoric—in a dilute state. It is, however, very useful to the gardener. If it is neutralised with carbonate of potash, an almost perfect, and certainly exceedingly powerful plant food is formed. This compound can be used occasionally in the summer as a stimulant at the rate of ¼–½ oz. per gallon of water.

PHOSPHORIC ACID.—The name phosphoric acid may mean one of any six or eight different acids, and the term "phosphate" may be one of a hundred compounds. Thus the gardener has to discriminate between various compounds. Of phosphoric acids *orthophosphoric acid* (H_3PO_4) is the most favoured by the gardener, and of the compounds of this acid, mono-calcium orthophosphate, which is soluble in water, is by far the most useful when it can be obtained. More frequently, however, the only cheap form of phosphoric acid is found in *superphosphate*, a mixture of mono-calcium orthophosphate, calcium sulphate, and tri-calcium orthophosphate—the last two named compounds being insoluble in water. As superphosphate is frequently terribly adulterated, chiefly with cheaper crushed gypsum or more rarely with insoluble phosphate, its soluble phosphates should, prior to purchase, be estimated either in the way described under CITRIC ACID or the way described under SULPHURIC ACID. Phosphoric acid in some form or other is essential to all plant-life, and is especially so in the case of crops grown for their seeds.

SULPHURIC ACID (H_2SO_4).—Oil of vitriol is a familiar liquid to many gardeners. Its uses are many and varied. It is an ingredient of some of the best weed killers, and paths can be cleared of weeds by watering with a diluted solution of this acid once during the early summer. It can be used for dissolving bones, and the method of working is described in the notes on *BONES*, to which the reader is referred. It can also be used for dissolving coprolites, and a material similar to *superphosphate* is produced in both cases. A drop of this acid put into the crown of a dandelion or plantain by means of a skewer will kill the plant. Mixed with fine ashes and crushed pumice, sulphuric acid forms a useful material for cleaning glass, much safer than HYDROFLUORIC ACID. As great heat is produced when water comes in contact with this acid, the gardener should stand quite clear, and right to the windward of the structure when he uses his hose pipe to wash off the acid. It must not come into contact with woodwork, or the wood will be destroyed.

Sulphuric acid can be used for roughly estimating the amount of soluble phosphate a given sample of *superphosphate* can produce. First of all weigh a sample of the superphosphate and put it into a pot of 2 per cent. citric acid. Stir well and filter. Dry the residue and weigh it. Subtract this from the original weight taken and you have the weight dissolved. Now take a simple quantity, say 1 oz. of this residue, and put it into a

small weighed glazed porcelain dish. Cover it with strong sulphuric acid and stir with a glass rod. Digest in this way for a day, stirring from time to time, and then pour the contents of the dish very slowly and carefully into a glass beaker containing a quantity of cold water. Now protect your hands and face, and holding the dish away from you pour a little cold water into it to rinse out the remaining contents into the beaker. Stir well and test a drop of the solution in a piece of blotting-paper. If it makes a brown charred mark add more water. Then filter the solution, dry and weigh again (the filter-paper should of course, if large, have been previously weighed).

The residue is insoluble, and from this you can obtain by simple calculations, first the weight of directly soluble phosphates, secondly the weight of indirectly soluble phosphates, and the weight of insoluble matter which remains must be calculated as the waste product. This method is an exceedingly useful one, and if the percentage of "second phosphates," as they are called, is large it might be advisable to treat the material as advised under *Bones* to dissolve it. At any rate the percentage of "first" or directly soluble phosphates should be over 25 per cent., and 35 per cent. to 40 per cent. is much better. If under 25 per cent. the material should be refused.

SULPHUROUS ACID (H_2SO_3).—The last of our dozen acids has limited applications in the gardener's mind. It is produced by burning sulphur in a thoroughly damp atmosphere. It is a very pungent compound with a most searching smell and highly irritating to the eyes, nose, and throat. When a glasshouse has become thoroughly foul with any kind of pest there is usually but one remedy. The plants are removed to the potting shed and drenched with some good insecticide, and then the house is thoroughly damped down with a syringe. Finally a quantity of sulphur is put in an iron plate and a match set to it. A pound of sulphur will be ample for a small house. For further information, precautions to be taken when entering fumigated houses, the reader should refer to the special article on *Fumigating*. The popular name of this acid is Sulphur Dioxide, as it is really a solution of this gas in water.

Before closing this article on Acids it will be well to warn readers that all the strong acids need handling with very great care. Most of the acids just mentioned burn holes in one's garments and one's flesh, producing severe wounds if care be not taken. The more gaseous acids give off fumes which are very harmful and unpleasant. Thus very great care is needed in using them. A golden rule to make when diluting any strong acids is to pour the acid into water, and not the water into the acid. If this is done there is much less danger.—E.

See also *Chemistry for Gardeners*.

ACINETA.—See *Orchids*.

ACIPHYLLA (Spear Grass. Nat. Ord. Umbelliferæ).—This genus is not of any great importance, and only three species are grown at Kew. These succeed in light moist soil, and may be planted in the perennial border, rock garden, or wild garden. Propagation may be effected by seed or division of the roots, and the best time to plant or divide is in late March. The sort most often grown is *A. squarrosa*, the Bayonet Plant, which is a white summer-blooming species growing 2–3 yds. high.

ACIS. — Now included in the genus LEUCOJUM.

ACONITE.—See *MEDICINAL HERBS.*

ACONITI RADIX.—See under ACONITE in *MEDICINAL HERBS.*

ACONITUM (MONKSHOOD. Nat. Ord. Ranunculaceæ).—This is a desirable though intensely poisonous plant, and where there are many children who are allowed to work in the garden, it should be banned altogether, to ensure safety. The whole plant is poisonous, and both seeds and roots are in request by herbalists, as a powerful drug is obtained from them. See article on *MEDICINAL HERBS* for particulars about this. The roots of some may easily be mistaken for those of Chicory, and the tuberous roots of others may be mistaken for those of the Jerusalem Artichoke, hence the plants should be introduced with care. However, they are exceedingly attractive both for use in the perennial border and the shrubbery border, or even in the wild garden, and those who like colour of flower and foliage (the last is a deep and intense green) will not be able to dispense with these plants.

Culture.—The plants can be grown without difficulty by the beginner or experienced gardener alike. They will succeed in sun or shade, though the spikes if required for cutting are best from plants grown in the sun. They may be raised easily by seed sown in the spring or summer in the usual way, though at times it does not germinate very well. They are also easily propagated by division of the roots in November, February, or March. It is advisable, however, to do this work in gloves in case the poison from the roots should get into any cracks in the hands and cause blood poisoning or death. Certainly every piece of crown will grow. Any soil suits them and also any manure. Lifting and division should be done about once in three years, the best time for this work or planting being in the autumn or spring.

What to Grow.—There are numerous species which are splendid. We advise the following :—

Aconitum album.—See *A. variegatum album.*

A. angustifolium.—A form of *A. Napellus,* which see.

A. autumnale.—This species often offered in plant catalogues is really synonymous with *A. Fischeri.*

A. barbatum.—A synonym for *A. Lycoctonum,* which see.

A. bicolor.—See *A. variegatum.*

A. chinense.—This tall Chinese sort is said to be synonymous with *A. Fortunei.* It is a blue summer flowering sort and grows 6 ft. high or more.

A. Fischeri (Syn. *A. columbianum*). —A pale blue late flowering sort coming into bloom from September onwards. Height about 3 ft.

A. Fortunei.—A desirable tall blue flowering sort blooming from late June into October. Height about 6 ft.

A. Halleri.—This is a form of *A. Napellus,* which see.

A. japonicum.—A useful creamy-pink sort blooming from July to September. Height, 4–5 ft.

A. Lycoctonum (Syn. *A. barbatum*). —A yellow-flowering species blooming from late June onwards into early August. Height, 3–4 ft.

A. Napellus.—Probably this is the most popular species of all Aconitums. There are many good sorts and they are being improved year by year. The flowers are dark blue, often of the deepest ultramarine. The flowering period ranges from June to August. The height ranges from 4 ft. upwards. Plants which are well suited as regards position often grow up to 7 ft. or so in height. There are several varieties of this :

A. N. angustifolium is blue and flowers early, while *A. N. Halleri* is blue-purple and also early flowering.

A. variegatum.—This is not a specially good sort, but its blue and white flowers make it worthy of inclusion in fairly representative collections. It is sometimes known to nurserymen by the name of *A. bicolor*. It flowers in the late summer, and ranges from 4 ft. upwards in height. The white variety, *A. v. album*, is also useful.

A. Wilsoni.—A desirable blue sort coming into flower in August and sometimes earlier. It will continue to bloom well into the autumn. It is a tall sort; the writer has seen it 6½ ft. in height.—E.

NEW VARIETY.

Aconitum Napellus album grandiflorum.—This is a charming white-flowered Monkshood, bearing long, pyramidal spikes of bloom and finely divided leaves.

See also *CLIMBING AND TRAILING PLANTS*, and under ACONITE in *MEDICINAL HERBS*.

ACORUS (SWEET FLAG. Nat. Ord. Araceæ).—This is an unimportant genus of hardy herbaceous perennial and aquatic plants of no great value to gardeners. *A. Calamus*, popularly known as SWEET SEDGE or MYRTLE GRASS, is a useful medicinal plant, and is described under the former name in our article *MEDICINAL HERBS*. Another good species is *A. gramineus*. The first grows about 2 ft. in height, while the latter only attains a height of 6 ins. The Sweet Sedge must be carefully distinguished from the other Sedges described in our article on the genus *CAREX*.

See also SWEET FLAG in *WATER GARDEN: PLANTS FOR THE*; also SWEET SEDGE in *MEDICINAL HERBS*.

ACOSMIA.—Now included in the genus *GYPSOPHILA*.

ACROCLINIUM.—Now included in the genus HELIPTERUM.

ACROPHORUS. — Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING*.

ACTAEA (BANEBERRY and HERB CHRISTOPHER. Nat. Ord. Ranunculaceæ).—This is not very often grown, since the berries are distinctly poisonous. It will grow freely with the usual treatment for hardy perennials, in the wild garden, or shady border in the rock garden. Any good garden loam suits it. Plant at the usual time, and increase by division in the autumn or spring. It may also be raised from seeds sown in a frame in the spring.

What to Grow.—The following may be included:—

Actaea alba.—As its name implies, this is a white sort. It blooms in late April and May, and averages about 15 ins. in height.

A. spicata.—This also is white, but bears black berries. It blooms at the same period as the species just described and varies from 1 to 3 ft. in height according to site.

A. spicata nigra.—This is a dark variety of the sort below.

A. spicata rubra.—A red-berried sort bearing white flowers in April and May. Its height varies, but averages about a yard.

ACTINIDIA.—For the best species see *CLIMBING AND TRAILING PLANTS*.

ACTINOMERIS (Nat. Ord. Compositæ).—A little known, and consequently infrequently grown, North American plant with daisy-like flowers. Being an herbaceous perennial and hardy at that, it comes in for the perennial border, the shrub border, or even the more open parts of the wild garden. It is not particular as to soil or site, any fairly kind earth or open site being suitable. Some people mistake it for the Sunflower (*Helianthus*), with which it is more or less

closely allied. It is easily propagated by seed sown in the usual way in the spring, or by division of the rootstock in February, and it may be planted any time during the winter and up to the end of March.

What to Grow.—Only one species is at all generally grown, the others may be relegated to botanical collections. This species (*A. squarrosa*) is a yellow flower bearing its blooms from July onwards. Its height averages about a yard.

ADA.—See *Orchids.*

ADAM'S NEEDLE (*Yucca gloriosa*).—See *Yucca.*

ADDER.—See *Snakes.*

ADDERS TONGUES. — See *Dog's Tooth Violets.*

ADENOCARPUS.—For the best species see *Shrubs.*

ADENOPHORA (Nat. Ord. Campanulaceæ).—This genus is one of the several little known and seldom grown hardy herbaceous perennials. The flowers, however, are rather pretty, and the genus is well worth including in large borders where a fair-sized collection is represented. Being of the Campanula order its flowers are not unlike those of the well-known Bellflower, and, in consequence, the prevailing colour is blue.

Culture.—This is not a matter of great difficulty. Any ordinary well-manured soil will suit the plant, so long as a damp, shady, sour silt is avoided. The plant is easily propagated by seeds sown in the usual way, as is described in our article *Perennials, General Culture of.* It may also be increased by division of the roots in the spring, at which time planting is best done.

What to Grow.—The writer is informed by a hardy plant specialist that more than twenty species have been described. A good many are, however, of little consequence and only known to botanists and similar students. The following are recommended :—

Adenophora coronata (Syn. *A. marsupiflora*).—A blue sort coming into bloom in July, and averaging 24 ins. in height.

A. coronopifolia.—This is also blue, but comes in earlier. We have seen it in full flower in June. Its height averages 18–24 ins.

A. denticulata (Syn. *A. tricuspidata*).—This is a blue July blooming sort, averaging 12–18 ins. in height.

A. Fischeri.—This useful blue species coming in during late July and August is closely allied to *A. liliifolia.* It is about 24 ins. in height.

A. intermedia.—Also blue, this sort flowers about the same time as *A. Fischeri,* and is of similar height. It is probably a variety of the above.

A. Lamarckii.—A useful blue early flowering sort coming in during June. Its height averages 18–24 ins.

A. liliifolia.—Probably this is the best known of any. It is a bluish sort flowering during June, July, and August, and its flowers are scented. Its height varies with the variety from 15 ins. to 36 ins.

A. Rabelaisiana.—A blue sort coming in during late July and continuing into August. Height, 18–24 ins.

A. reticulata.—Also blue, this sort, flowering as it does from late June onwards, averages 24 ins. in height.

A. stylosa.—A dwarfer bluish sort flowering in May and June. Its height averages 12–18 ins.

A. verticillata.—A blue sort coming in about midsummer, and averaging 24–30 ins. in height.—E.

ADENOSCILLA.—Now included in the genus *Scilla.*

ADENOSTYLES (Nat. Ord. Compositæ).—This comparatively little known genus used to be united with *Cacalia, C. albifrons,* and *C. alpina,* now being *A. albida* and *A. viridis* respectively. Both are hardy herbaceous perennials of easy culture and thrive in ordinary loam. They may be propagated by seed or division in the usual way, and the most successful time to plant is from November to March. We briefly describe the two species below :—

Adenostyles albida (Syns. *A. albifrons, A. Petasites,* and *Cacalia albifrons*).—A white July blooming plant growing about 2 ft. high..

A. viridis (Syns. *A. alpina, A. glabra,* and *Cacalia alpina*).—A purple July blooming plant growing about half a yard high.

ADIANTUM.—For the best species and varieties see *Ferns and Fern Gardening.*

ADONIS (Nat. Ord. Ranunculaceæ).—A small group of hardy plants, mostly herbaceous, but containing a few annuals. Their bright flowers, produced in early summer, in a setting of elegant foliage render them attractive, while their modest stature makes them suitable for the rock garden.

Annual Species.—The two best are briefly described below :—

Adonis aestivalis (Syn. *A. ambigua*). — This produces crimson-scarlet flowers in May and June, and averages 15 ins. high. Sow in the open in March ; or the middle of August.

A. autumnalis.—A British plant known under the popular names of Corn Adonis, Pheasant's Eye, and Red Chamomile. Its flowers are blood-red with dark centre, and open in June, or earlier from autumn-sown plants. The height is 12–18 ins.

Rock Garden Species. — All the four perennial species are suitable for the rock garden. They require a deep loamy soil, and are easily propagated by dividing the roots in autumn or spring. They may also be raised from seeds sown in gentle heat in March, but these take a long time to germinate.

Adonis amurensis.—Leaves in tufts, deeply divided and fern-like. Flowers large golden-yellow, 2 ins. across. Site half-shady or sunny. Soil deep loam. Flowering Period, February to March. Height, 1 ft.

A. pyrenaica.—A tufted plant with fern-like leaves. Flowers bright yellow. Site half-shady. Soil deep loam. Flowering Period, April to June. Height, 1 ft.

A. vernalis.—Like the above in habit, but easier to grow. Leaves fern-like. Flowers large golden-yellow. Site open. Soil deep loam. Flowering Period, March to April. Height, 9 ins.

A. Walziana.—Like the above, but blooms later. Leaves more finely divided. Flowers yellow. Site open. Soil deep loam. Flowering Period, April to May. Height, 1 ft.

ADVANTAGES OF CORDONS. — See *Cordon Fruit Trees.*

ADVICE ON MARKET GARDENING.—See *Market Gardening* and *Women Gardeners.*

ADYSETON.—Now included in the genus *Alyssum.*

AECIDIAL STAGE.—See *Rust Fungi.*

AECIDIOSPORE STAGE.—See *Rust Fungi.*

AEGERIA.—See Currant Clearwing in *Insect Pests.*

AEGILOPS. — Now referred to the genus *Triticum.*

ÆGLE.—For best species see *Shrubs.*

ÆGOPODIUM (Nat. Ord. Umbelliferæ).—This is a genus of strong growing and highly troublesome weeds. The most notable species (*Æ. Podagraria*) is described under Gout-weed in our article on *Weeds.*

ÆGOPOGON (Goats-beard Grass. Nat. Ord. Gramineæ).—This is a genus of hardy grasses, easily grown in the wild garden, but not of much consequence. The best known species is *Æ. geminiflorus* (Syn. *Æ. pusillus*), which grows about 6 ins. high.

ÆRIDES.—See *Orchids.*

ÆSCULUS.—For the best species see *Trees.*

ÆTHIONEMA (Burnt Candytuft. Nat. Ord. Cruciferæ).—Many of the perennial species are suitable for the rock garden. These thrive in well-drained sandy soil in a sunny position, and are propagated by cuttings in July or by seeds in March.

Rock Garden Species.—The best are briefly described below :—

Æthionema amoenum.—Shrubby. Leaves glaucous, entire. Flowers pink in long racemes. Site, sunny ledge. Flowering Period, May to June. Height, 9 ins.

Æ. coridifolium (Syn. *Iberis jucunda*). — The bushy Lebanon Candytuft. Leaves glaucous. Flowers rosy-pink. Site, sunny ledge. Soil gritty. Flowering Period, June to July. Height, 6 ins.

Æ. grandiflorum.—Shrubby. Leaves glaucous. Flowers rosy-pink in long racemes. Site, sunny ledge. Flowering Period, June to July. Height, 1–1½ ft.

Æ. pulchellum.—Shrubby. Leaves very glaucous. Flowers rosy-purple. Site sunny. Soil gritty. Flowering Period, May to June. Height, 6 ins.

ÆTHUSA (Nat. Ord. Umbelliferæ). Only one species of this is grown at Kew, namely, *Æ. Cynapium* (Syns. *Æ. elata* and *Æ. micrantha*), the well-known weed popularly called Fool's Parsley. It is a poisonous plant of no garden value whatever, and is described in our article on *Weeds.*

AFRICAN HEMP.—See *Sparmannia.*

AFRICAN LILY.—See *Agapanthus.*

AFRICAN MARIGOLD.—See *Marigold.*

AFRICAN OIL PALM (*Elaeis guineensis*).—See *Palms.*

AGAPANTHUS (African Lily. Nat. Ord. Liliaceæ).—This is a most useful plant for the greenhouse or conservatory, requiring very little attention, and increased by divisions or seed in spring. The soil should be good loam, with a little decayed leaf-mould and sand. Temperature needed, 40–45° F.

Greenhouse Species and Varieties.—*Agapanthus umbellatus.* — Blue. Flowers in August. Height, 2 ft.

A. u. albiflorus.—White. Flowers in August. Height, 1½–2 ft.

A. u. Mooreanus.—Blue. Flowers in September. Height, 1½–2 ft.

AGARIC. — See bleeding agaric, under Edible Fungi in *Fungi.*

AGARICUS.—See bleeding agaric under Edible Fungi in *Fungi*; See also *Mushroom.*

AGAVE (Nat. Ord. Amaryllidaceæ). This is a group of succulent plants requiring very little attention throughout the year. Large size plants are extremely ornamental during the summer months for the decoration of lawns and terraces ; they have a grand effect, and will stand the scorching rays of a summer sun unprotected. They are best propagated by suckers in the spring. Rich, loamy soil, decayed leaves, and brick rubbish is the best soil, and water must at all times be rather sparingly given. Temperature required, 45–55° F.

Greenhouse Species and Varieties :—*Agave americana.*—Yellowish. Flowers in August. Height, 2–6 ft.

A. celsiana.—Green. Flowers in May and June. Height, 2–4 ft.

A. densiflora.—Green. Flowers in September. Height, 2–4 ft.

A. filifera. — Greenish-white.

Flowers from July to August. Height, 2–4 ft.

A. flavescens. — Greenish-white. Flowers from July to August. Height, 2–4 ft.

A. Yuccafolia.—Yellow. Flowers from August to September. Height, 2–6 ft.

AGERATUM. — See *Annuals, Half-Hardy: List of.*

AGLAOMORPHA.—Now included in the genus Polypodium. See *Ferns and Fern Gardening.*

AGRIMONIA. — See *Agrimony,* and under Agrimony in *Medicinal Herbs.*

AGRIMONY (*Agrimonia.* Nat. Ord. Rosaceæ).—Those readers who are students of wild flowers, or who read Nature books, or made Nature rambles in their young days, will know this plant. And although Agrimony is a wild flower and not much grown, the four sorts *A. agrimonioides, Eupatoria, odorata,* and *suaveolens* may be included where space can be spared and where plants of this class are favoured. All the four species just named produce yellow flowers in June and July; they average 2 ft. in height, though at times they exceed this.

Culture.—This is easy. The plants grow without difficulty in ordinary good garden soil. Planting may be done any time in the autumn, winter, and spring. They may easily be increased by division of the rootstock in the autumn, or seeds may be sown and the plants grown in the usual way for perennials.

E.

See also *Medicinal Herbs.*

AGRIOLIMAX. — See Slugs and Snails in *Insect Pests.*

AGROPYRON (Nat. Ord. Gramineæ). This is a genus of weeds, including many species of *Triticum,* which see.

A. caninum (Syn. *T. caninum*) is the Dog's-tooth Grass, and *A. repens* (Syn. *T. repens*) is the well-known Couch Grass or Twitch described under the former name in our article on *Weeds.* We might name a host of the other species with their synonyms, but as none are worthy of culture we need not trouble the reader with them.

AGROSTEMMA. — Now included in the genus *Lychnis.*

AGROSTIS (Nat. Ord. Gramineæ). This is a genus of grasses which are not of any great garden value. The more ornamental species are described in our article on *Ornamental Grasses.* Bent Grass is a troublesome weed, and is mentioned in our article on *Weeds.* Some of the dwarfer species are used in lawn mixtures.

AGROTIS.—See under Surface Larvæ in *Insect Pests.*

AILANTHUS.— For the best species see *Trees.*

AIRA (Hair Grass. Nat. Ord. Gramineæ).—This is a genus of hardy grasses of little garden value thriving in ordinary soil. Probably the best known species is *A. caryophyllea,* the Mouse Grass. Most of the species are now classed with other genera.

AJAX.—Now included in the genus *Narcissus.*

AKAKASI (*Quercus acuta*). — See *Trees,*

AKEBIA.— For the best species see *Climbing and Trailing Plants.*

ALASKA CYPRESS.—(*Cupressus nootkatensis*).—See *Trees.*

ALBERSIA. — Now included in the genus Amarantus.

ALBUCEA. — Now included in the genus Ornithogalum.

ALCEA.—Now included in the genus *Althaea.*

ALCHEMILLA (Lady's Mantle. Nat. Ord. Rosaceæ).—This is a genus of hardy perennial and half-hardy greenhouse plants which are

chiefly desirable on account of their silvery foliage. We need not trouble with the greenhouse sorts, or with many of the hardy kinds. Two of the latter are, however, suitable for the rock garden; these thrive in well-drained soil in a sunny position, and are propagated by division of the roots in autumn or spring, or by seeds which germinate freely if sown in gentle heat in March.

Alchemilla alpina.—This is a tufted plant which in time will form a carpet. Leaves like those of the strawberry, silvery and evergreen. Flowers inconspicuous and greenish. Site sunny or open. Soil ordinary well-drained. Flowering Period, June to July. Height, 6 ins.

A. pentaphyllea.—This is a tufted plant with long fan-shaped divided leaves. Flowers white. Site open or half-shady. Soil gritty. Flowering Period, July. Height, 6 ins.

See also PARSLEY PIERT in *MEDICINAL HERBS.*

ALDER.—A name applied to the genus ALNUS. See *TREES.*

ALEYRODES.—See CABBAGE WHITE FLY in *INSECT PESTS.*

ALFREDIA. — Now included in the genus *CARDUUS.*

ALKANET. — A name applied to *ANCHUSA*, which see.

ALL-GOOD (*Chenopodium Bonus-Henricus*).—See *CHENOPODIUM.*

ALL SAINTS CHERRY (*Prunus acida semperflorens*).—See *TREES.*

ALLIARIA. — Now included in the genus *SISYMBRIUM.*

ALLIUM (Nat. Ord. Liliaceæ). Many of the species of this genus have their culture fully described under their English names, and readers should turn up our articles on *GARLIC*, *LEEKS*, *ONIONS*, and *SHALLOTS*, and our notes on CHIVES in the article on *SALAD PLANTS.* There are, however, a number of species which have attractive flowers, and these, though bulbs, can be treated as hardy perennials in the border or rock garden. They succeed in light loam in open sunny sites, and may be planted in the autumn or spring. They can readily be increased by sowing seeds in the usual way in spring.

Perennial Border Species.—A few of the large number known are briefly described below, all of which are hardy:—

Allium acuminatum.—A rose or dark purple-red sort flowering about July. Height, 8 ins.

A. amblyophyllum.—A purple July blooming sort about half a yard high.

A. backhousianum.—A white July blooming species about a yard high.

A. caeruleum.—A useful blue June flowering sort rarely exceeding half a yard in height.

A. Fetisowi.—Described by a trusted authority as a "rosy-lilac," this sort flowers during the summer months and averages about half a yard high.

A. giganteum.—Similar in colour to the above and flowering in June, this species may attain a height of a yard or more.

A. hoeltzeri.—A white summer-blooming sort about half a yard high.

A. medium (Syn. *A. triquetrum*).—A pure white June flowering species about 1 ft. high.

A. nigrum.—Syn. *A. pulchrum*, which see.

A. oxypetalum (Syn. *A. olgraceum*).—A white sort flowering in August and September and attaining a height of 1 ft.

A. pulchellum.—A scarlet sort blooming in July. Height, 1 ft.

A. pulchrum (Syn. *A. nigrum*).—A yellow June flowering sort of similar height to the above.

A. Purshii (Syn. *A. vineale*).—A pink August flowering sort about half a yard high.

A. roseum.—A rose or light pink sort blooming in June and July. Height, 12 ins.

A. triquetrum.—Syn. *A. medium*, which see.

A. vineale.—Syn. *A. Purshii*, which see.

A. violaceum.—A sort with violet coloured flowers which blooms in June. It grows about 1 ft. high.

Rock Garden Species.—About six species are useful. They are the dwarfer perennial kinds with attractive flowers. All thrive in an open position in deep loamy soil and are propagated by seeds sown in gentle heat in March.

Allium kansuense.—Leaves in tufts from small bulbs. Flowers blue in pendent heads. Site open. Soil ordinary. Flowering Period, June to July. Height, 6 ins.

A. macranthum.—Leaves tufted, long and narrow. Flowers rosy-pink. Site sunny. Soil deep loam. Flowering Period, June to July. Height, 1 ft.

A. Moly (Lily Leek).—Leaves glaucous. Flowers yellow. Site open. Soil ordinary. Flowering Period, June to July. Height, 1 ft.

A. narcissiflorum.—Habit tufted. Flowers rosy-purple in large pendent heads. Site sunny. Soil deep loamy. Flowering Period, May to June. Height, 9 ins.

A. neapolitanum (Daffodil Garlic).—Flowers white in umbels. Site warm and sunny. Soil deep loamy. Flowering Period, May to June. Height, 1 ft.

A. ostrowskianum.—A handsome species with tufted foliage. Flowers rosy-pink, large. Site sunny. Soil deep loam. Flowering Period, June to July. Height, 6 ins.

A. sikkimense.—Leaves grass-like in tufts. Flowers blue in drooping heads. Site open. Soil ordinary. Flowering Period, June to July. Height, 6 ins.

ALLOSORUS.—Now included in the genera Cryptogramme and Pellæa, for which see *Ferns and Fern Gardening.*

ALLOTMENT ACCOUNTS.—See *Accounts: Garden and Allotment.*

ALLOTMENT GARDENERS' AGREEMENTS.—See *Gardening Law.*

ALLOTMENT ORGANISATIONS: Their Value and Purpose.—In dealing with this subject one is struck with the fact that the allotment movement has, at a bound, taken a recognised place in our national life. Prior to 1914 allotments were familiar landmarks up and down the country, but allotments organised for a national purpose were practically unknown. The present position is a product of the war. But neither allotments nor the organisations which represent them will pass with the war. The great army of amateur land-workers, who, at a time of national crisis, rallied to the country's aid, have earned the gratitude of the nation. It is now the duty of those in authority to see that the men and women who made secure the food supplies of the nation in the hour of peril shall have their heart's desire—a permanent place on the soil of their native land.

Present-day conditions have in some respects changed, or enlarged, our pre-war views as regards the value and purpose of allotments. Prior to August 1914 an allotment was generally looked upon as a means of offering a useful opportunity to the casual employed, or under-employed, worker, to supplement his earnings. The next stage in the development of the allotment idea was the revelation that if we were unable to continue to import our food supplies we must grow them or go without. We wisely decided to grow them, and the allotment was at once accepted as a war-time expedient. We have, however, arrived at a further stage of development. Allotments are now recognised as being an all-time necessity.

The education of public opinion along this line has been as rapid as it is complete. In London, for example, in August 1914 there were some 500 organised plotholders. At the end of 1916 there were 6000. In August

1918 there were over 50,000, and this number was being constantly added to.

Taking the country as a whole, there were, by August 1918, according to the calculations of the Board of Agriculture, upwards of 1,500,000 allotments, with a total produce of as many tons, and the total value of the produce, calculated at the then current rates, was estimated at fifteen millions sterling. We may, therefore, safely come to the conclusion that the allotment has come to stay.

Prior to the Great War, however, there were those who saw in the allotment a valuable national asset, not only in regard to the production of food, but from a health and social point of view. Among them was the late Joseph Fels, who saw that in the land of a nation, rightly used, lay the health, happiness, and prosperity of that nation, and that idle land was a national eyesore and a national crime. He, having demonstrated in Philadelphia the practical value of cultivating waste pieces of land in that city, introduced the idea to London by founding in 1907 the Vacant Land Cultivation Society. The object of this Society was to utilise the vacant sites in our large cities for food-growing purposes. It was uphill work, and at the end of 1914, after seven or eight years' effort, only some 400 plot-holders had been enrolled in London, and one or two outposts established in the provinces. The difficulty was not to induce people to cultivate plots but to secure land for cultivation. Even during the two years which followed the outbreak of war, although the demand for allotments increased in volume, land on every hand was lying idle. It required an Order under that drastic measure, the Defence of the Realm Act, to secure possession of land for which the demand was so urgent and the need so plain. The result was immediate and phenomenal. Within a year from the putting into operation of the Cultivation of Lands Orders (1916), the plot-holders of the V.L.C.S. alone increased to over 6000, and the value of produce raised in that year from this source from previously derelict land was estimated at over £60,000.

The V.L.C.S. took a leading part in the formation of the National Union of Allotment Holders, which body is now organising allotment societies throughout the country. The objects of the National Union are: To secure land in every district, urban and rural; ensure that it shall be used in the most effective manner and give to the plotholders: (1) Instruction where necessary; (2) assistance in the shape of lectures, demonstrations, shows, etc.; (3) advice as to the purchase of seeds, etc., on the co-operative principle, and practical help in the overcoming of any difficulties. But one of the chief functions of the Union is the banding together of the plotholders in order to facilitate united action for securing such legislation as the future may require.

The method adopted by the National Union in its organising work is the formation of local societies under their own honorary officers and democratically elected committees, the grouping of them into associations or federations, and finally linking them up in divisional sections, which in turn are united under a nationally elected executive. Already several valuable contributions in the shape of books of technical instruction have been issued. A national monthly organ, *Allotments and Gardens*, has been started, which is recognised as being of great value in advising, consolidating, and strengthening the movement.

It required Armageddon to bring home to the British people the extent of their dependence on outside sources for their daily existence. But the allotment movement has demonstrated that, given access to the land, the people of this country can, and will put an end to the danger of food shortage. It has also shown the advantage to be gained by the bringing into close touch and association all classes of the community, thus breaking down class and social barriers, moulding individual characters and uniting all sections of the community, a result which must have a far-reaching effect upon the home life of the nation. —F. S.

[The objects of the National Union may well be taken as the foundation for the rules and objects of any allotment organisation or association, however small it may be. A very large number of these bodies even now exist solely for exhibition purposes, and spend all their funds on having an annual show which is of very little practical use to any one. Practical instruction is often completely neglected. Lectures are, except in the case of "go ahead" associations, considered

unprofitable and too risky and doubtful to be taken on. Co-operation in seed and manure buying also is far too seldom found as part of the duties of an allotment society. But if societies would only apply these matters they would not merely be helping their own members, but they would be vastly helping the country by increasing the amount of food produced.—EDITOR.]

ALLOTMENTS : Increased Production on.—See *INCREASED PRODUCTION ON ALLOTMENTS.*

ALLOTMENTS : MANAGEMENT OF. Allotment gardening has become such a universal pursuit that the Dictionary would, we think, be incomplete without an article on Allotment Management, so we give a brief sketch below. We think that the allotment gardener will find the Vegetable Garden Calendar very useful for telling him what to do at each month of the year, adapting it to the special needs of his case.

In the management of an allotment, tools are our first consideration. So often the tools amateurs try to use when starting an allotment are toy tools in the fullest sense of the word. But they should not be toy tools: they should be proper garden implements, made of tempered steel, with light wood handles.

Of the tools necessary, we of course mention first of all the spade, a digging-fork, and a rake. After these, two hoes, a pull hoe and a push hoe, a small potato fork, a water can, a trowel, and a 60-yard garden line will be required. A wheelbarrow is not absolutely essential to complete the outfit, but it will be found very useful.

In addition to tools; manures, seeds, lime, etc., will have to be purchased. Elaborate tables of the needs of amateurs in these directions will be found in any of the many allotment books which are now on the market, and we do not, thus, propose to include such directions here.

Allotments should be started in the winter months. Then one realises to the full the sorrows and labour of this kind of food production. Even so one confesses the following autumn as the crops are taken home that the labour and sorrow have been worth while. As we wheel our produce home we forget how many times we have been wet through, or chilled to the marrow, during the past winter when digging our plot, and a good thing too.

Winter Digging.—When we have our tools the sooner we start digging the better. Our plot will probably be a piece of rough meadow land, and we have first of all to decide how to tackle it best. This rather depends on the nature of the sod. If the sod is teeming with vicious rooted weeds, no good purpose but a very bad purpose would be served by turning it in; if on the allotment the sod is mostly fine springy meadow grass it would be a thousand pities not to turn it in.

Amateur allotment holders wishing to save themselves trouble are very apt to decide to have their plots ploughed up, instead of digging them. No mistake could be greater, and no blunder more disastrous in its effects. The writer has seen plots ploughed up, he has seen the multi-millions of weeds which grow on them, and he has seen the poor worthless crops which struggle against stifling, yet succumb to it. Even when the plots are properly dug many thousands of weeds appear, but these are nothing to the weeds resulting from ploughing. Double-digging is, we consider, the ideal for allotments; it is better than trenching, for in trenching the foul material —sour subsoil—is brought up to the top and the good soil buried. Double-digging is described in the article on

Soil Cultivation, to which readers are referred for full particulars. In double-digging meadow land the sod is buried at the bottom of the first spit. The clod, of sod and soil, on each spade should be turned absolutely upside down; if it is tilted on one side it will start growing to the surface and give a lot of trouble.

A very rough weedy plot should be treated differently. Undoubtedly the best plan is to pare off the sod. To do this very speedily a turf cutter and turfing iron are needed; it is a long and laborious task lifting the sod with the spade. The sod pared off should be made into a stack and burnt at once in a slow, smother fire, the resulting material being spread on the surface ground. The land is then double-dug in the ordinary way.

A question of winter allotment management of some importance is that of whether to dig the manure in or spread it on the surface. We consider manure spreading to be a dirty method of cultivating, and one which should never be followed. It involves great waste, encourages the enemies of the gardener, and is in every way a very undesirable method of cultivating. Far better to dig the manure in at once, and thus conserve to the full its fertilising value in the soil.

The dug ground of the allotment should be left as rough as possible, so that the frost can break down the lumps. Ground does not look so tidy thus, but it is far better for it, and for the crops which are to follow.

Seeds should be bought early, and not left until the last moment when most of the best varieties will have been sold out. The amateur should not be tempted by specious circulars, catalogues, and advertisements of "cheap lots." These lots cost a fortune in the end, for they mean a whole wasted season. The amateur should go to a reliable seedsman only, a firm with a big name to keep up, and not one that advertises much — big firms get plenty of customers without putting flaring advertisements in the Press.

Spring Notes. — When the spring comes, the amateur finds that every moment of his available time is taken up by sowing or planting the various crops. The first, of course, are artichokes, broad beans, and shallots in February, but these are quickly followed in March by a host of vegetables—indeed we might say that every crop is sown during the first month or six weeks after 1st March. The allotment holder should study the Calendar and act accordingly.

In sowing or planting any crop the tendency is to try to grow too much in one spot. We have known amateurs plant artichokes and main-crop potatoes only 6 ins. apart each way, and yet expect to get a heavy crop. It is a common trick to sow carrots, lettuces, parsnips, spinach beet, turnips, and other crops in rows about five times too thickly. If amateurs could only realise the immense value of thin sowing they would be vastly more successful in their results. For further information on sowing, amateurs should read the article on *Seed Sowing*, published further on.

Kinds and varieties of vegetables is another important matter in the spring. It is a very good plan to have as many different kinds of vegetables on the allotment as possible, for a change of vegetables is very pleasant and desirable. As regards varieties, amateurs are apt when they have once found a named variety of a vegetable to do well, to stick to it. This is a very great mistake. New varieties of our well-known vegetables ought

certainly to be tried as often as possible by amateur allotment holders, and as small packets of these can be obtained from certain seedsmen advantage should be taken of them to try new varieties which are frequently so far in advance of anything grown previously.

It is in the early spring that the first attack has to be made on the weeds. Before April is half through it will be hard indeed to tell which are crops and which weeds. The push hoe is ideal for surface weeding, and the pull or draw hoe for cutting up well-established weeds. Care has to be taken during the first hoeing not to injure the crops in the rows as well, and this care is specially needed in the case of salsafy, which when it first appears is almost indistinguishable from grass. Supposing the weeds get a good start before the rows of crops show, a good plan is to stretch the garden line along each row, and hoe to within 2 ins. of each side of it.

Slugs and other pests will be very troublesome in the early spring among the young crops. We find that old soot is invaluable for checking these marauders. It is dusted freely over the rows, and renewed every time rain falls. Lime can also be used, but this is apt to burn the foliage. Wireworms can be trapped by means of sunken pieces of turnip and potato.

In the spring, the thorough thinning out of allotment crops will be a matter of some considerable importance. This should have been reduced to a minimum by extremely thin sowing, since much time and seed are wasted by thinning out the crops. The thinning should, of course, be done on a damp day, and the earth should be very slightly drawn up to the rows to fill in the holes thus formed.

Summer Sowings.—There are many crops which are sown in the summer, as the Calendar will show. Probably the most important of these is the spring cabbage, which should be sown in firm ground in June, July, or August according to the district.

Inter-cropping becomes of importance in the summer. It is a great mistake to leave land lying idle for a day longer than it need. Get some crop sown or planted in it, even if it is only spinach, and so prevent waste. Everyone, for instance, should grow spinach beet for winter and spring use. This can follow ordinary spinach, which is taken off in early September when sown in June on land just cleared of early peas. With luck a gathering may be got early in November, after which cutting will be continuous from February or March to July.

Constant weeding and hoeing throughout the summer will be needed if the garden is to be kept clean and the crops to get all the food they need.

A question of summer management of allotments is the efficient disposal of weeds. This matter demands careful thought, for on it may depend the future success or failure of the garden. The need for producing manure is great and this should be realised, but if the manure is merely a mass of weed seeds and live roots it will do more harm than good. The question is dealt with in the articles on *Weeding* and *Vegetable Matter*.

Throughout the summer and autumn a sharp eye should be kept for the appearance of any diseases of crops, some of which, notably the Wart Disease of Potatoes, are notifiable to the Board of Agriculture under penalty of a heavy fine.

Autumn Harvesting. — Watering of food crops is a matter of some importance in the summer and

autumn. If this is done at all it should be done thoroughly, as is mentioned in the article on *Watering*.

The special item in the autumn management of allotments is, of course, harvesting and storing the crops. Proper harvesting and efficient storage are items of immense importance, failure to observe them frequently resulting in the total loss of the crop. Particulars of how to harvest and store crops will be found in some of the articles on vegetables in this Dictionary. They are given in many books on gardening, and instructions appear in the autumn in most of the gardening papers.

Autumn Weeding is of some importance, and after that comes the clearing up of the land. All potato haulm should be burnt, and any haulm or growth of crops which are in the least bit diseased should also be calcined and the ashes spread on the land.

Autumn or very early winter double-digging is of great importance, manure being applied at the same time, except in the case of very light sandy soils, which should not have any manure till the spring.

This brings us to the end of our very short sketch of Management of Allotments. In addition to the articles referred to already, allotment holders are advised to read the articles on *Ammonia*, *Lime*, *Manuring*, *Potash*, and *Soda*, which are published further on in the Dictionary.—E. T. E.

ALLSPICE.—A name applied to the genus Calycanthus. See *Shrubs*.

ALLWOODII (*Dianthus Allwoodii*. Nat. Ord. Caryophyllaceæ).—This is a new plant introduced by Messrs. Allwood Bros., obtained by crossing the Perpetual Flowering Carnation with the Garden Pink. It is perfectly hardy and requires no more than ordinary border cultivation. Its flowers partly resemble the Carnation and partly the Pink, while its habit of growth is similar to that of the Pink, but perpetual growing and flowering.

Propagation is easily effected by layers, pipings, or cuttings from May to September, and by root division in March. Pot plants under glass can be forced into bloom during the autumn, winter, and early spring. It is a grand plant for the unheated conservatory and for growing in window boxes, lawn vases, etc. It is very useful for cutting, and the flowers are all sweet-scented. A single plant will live out of doors without propagation for upwards of four years.

Varieties.—The following are recommended:—*Albert* (pale mauve); *Dorothy* (rose-pink); *Harold* (double white); *Jean* (white with violet centre); *Mary* (rose-pink); *Phyllis* (lilac); *Robert* (old rose); *Rufus* (pale maroon); and *Susan* (lilac with black eye). All these flower from May to November, and average 12 ins. in height.

ALMOND (*Prunus Amygdalus*).—See *Nut Culture* and *Trees*.

ALMOND-LEAVED WILLOW (*Salix triandra*).—See *Trees*.

ALNUS.—For best species see *Trees*.

ALOE (Nat. Ord. Liliaceæ).

This is a genus of interesting evergreen succulent plants chiefly from the Cape of Good Hope. They are very ornamental for the greenhouse or conservatory, and of easy culture, requiring very little water during the winter months. They are best propagated by suckers in spring. The most suitable soil is sandy loam and peat, with a little decayed leaf-mould, and plenty of brick and lime rubbish, to ensure good drainage. Temperature required 45–55° F.

Greenhouse Species :—*Aloe abyssinica.*—Yellow. Flowers from June to July. Height, 2–3 ft.

A. glauca.—Red. Flowers from April to May. Height, 2–4 ft.

A. plicatilis.—Reddish-yellow. Flowers from June to July. Height, 2–6 ft.

A. saponaria.—Red. Flowers from July to August. Height, 2–4 ft.

A. striata.—Scarlet. Flowers from July to August. Height, 2–4 ft.

ALONSOA (Mask Flower. Nat. Ord. Scrophulariaceæ).—This is a most useful and brilliant flowering plant, suitable for pot culture, for the greenhouse or conservatory. It also does well in the open in a warm sunny spot. Propagation is best effected by cuttings or seeds. The former should be inserted in sandy loam in August or March under hand-light or frame in slight heat; the seeds in February or March in gentle heat. The best soil is light rich sandy loam and leaf-mould. Temperature required 45–55° F.

Greenhouse Species and Varieties :—*Alonsoa linearis.*—Scarlet. Flowers from June to August. Height, 1–2 ft.

A. linifolia.—Scarlet. Flowers from June to August. Height, 1–2 ft.

A. myrtifolia.—Scarlet. Flowers from June to August. Height, 1–2 ft.

A. Warscewiczii.—Crimson. Flowers from July to August. Height, 1–2 ft.

ALOPECURUS (Fox-tail Grass. Nat. Ord. Gramineæ).—This is a large genus of grasses of no very great consequence to gardeners. Probably the best known is *A. pratensis* (Syn. *A. obscurus*), and its variety *foliis variegatis*. The Black Fox-tail Grass, *A. agrestis* (Syn. *A. purpurascens*), and the Elbowit Grass, *A. geniculatus*, are sometimes grown in the wild garden.

ALOYSIA (Lemon-scented Verbena. Nat. Ord. Verbenaceæ).—A greenhouse deciduous shrub with lemon-scented leaves, propagated by cuttings of young shoots in spring in gentle heat, under bell-glass or frame, in a soil of good loam, peat and sand. Temperature needed, 35–45° F.

Greenhouse Species.—*Aloysia asperifolia.*—Red. Flowers in July. Height, 1½–3 ft.

A. citriodora (Sweet Verbena).—Pale purple. Flowers in August. Height, 1½–6 ft.

ALPINE AURICULAS.—See *Auricula.*

ALPINE BLADDER FERN (*Cystopteris alpina*).—See *Ferns and Fern Gardening.*

ALPINE CATCHFLY (*Silene alpestris*).—See *Silene.*

ALPINE CLEMATIS (*Clematis alpina*).—See *Climbing and Trailing Plants.*

ALPINE COMFREY.—See *Onosma.*

ALPINE EVERLASTING (*Antennaria dioica*).—See *Antennaria.*

ALPINE FOREST HEATH (*Erica carnea*).—See *Heaths.*

ALPINE GARDEN.—See *Rock Garden: Making a; Rock Garden: Management of,* etc.

ALPINE HARD FERN (*Lomaria alpina*).—See *Ferns and Fern Gardening.*

ALPINE HOUSE.

This is yet in its infancy, but it will some day be the most popular glass structure in the garden. The plants which may be grown therein are most fascinating, and the wealth and variety of bloom available, from the New Year to Midsummer, is quite equal to that in heated greenhouses or conservatories. From July onwards there are fewer flowers, it is true, but interest is kept up by the neat and compact pans of foliage in varying shades and forms.

The charm of the Alpine House, however, lies in the fact that choice and early flowering rock plants can be viewed in all their beauty, spotless and unsoiled, in comfortable surroundings, when outside conditions prevail that do not allow daily visits to the rock garden ; also that plants which are difficult to cultivate outside, adapt themselves to indoor treatment and can be grown with every prospect of success.

Our own Alpine House is a well-built rather low span-roof structure, with a central pathway and side stages. It has a shelf running along the back of each stage, for the benefit of plants that require to be grown in the lightest position possible. It runs east and west, and is glazed as all houses should be, so as to admit the maximum of light.

We find that shading is necessary during the sunniest part of hot days, since if the temperature rises unduly the plants do not remain long in bloom. Roller blinds are a convenient means of shading.

Ventilation is an important point, and sufficient air must be admitted night and day to keep the atmosphere fresh and cool, excepting foggy days and keen frosty nights.

Some Suitable Subjects. — Below we give a list of some of the best of the many suitable plants for the Alpine House. Many will be found fully described under their generic names in alphabetical order in this work :—

Adonis amurensis.
Androsace carnea, A. Chumbyi, A. primuloides.
Anemone blanda.
Asperula Gussonii.
Campanula alpina, C. Allionii, C. pulla, C. Steveni nana, C. pusilla.
Crassula Saracaulis.
Daphne rupestris.
Dianthus alpinus, D. neglectus.
Draba Aizoon.
Drosera rotundifolia, D. longifolia.
Gentiana verna.
Hepatica triloba.
Lewisia Cotyledon, L. Howellii.
Meconopsis aculeata, M. integrifolia, M. quintuplinervia, M. puniceus.
Mertensia primuloides.
Morisia hypogaea.
Nierembergia rivularis.
Œnothera pumila.
Oxalis adenophylla, O. enneaphylla.
Phyteuma comosum.
Pinguicula vulgaris.
Primula capitata, P. conspersa, P. denticulata, P. denticulata alba, P. farinosa, P. farinosa alba, P. scotica, P. Forrestii, P. frondosa, P. Juliae, P. hirsuta nivea, P. marginata, P. marginata grandiflora, P. Marven, P. Reidii, P. viscosa, P. P. J. H. Wilson.
Rhododendron intricatum.
Saxifraga Boydii, S. bursiculata, S. burseriana Gloria, S. diapensioides, S. Faldonside, S. Griesbachii, S. Irvingii, S. longifolia, S. oppositifolia, S. Paulinae, S. Petraschii, S. retusa, S. squarrosa, S. thessalica, S. valdensis.
Sedum obtusatum, S. pulchellum, S. spathulifolium.
Sempervivum arachnoideum, S. Chrysanthemum, S. giganteum, S. Laggeri.
Shortia galacifolia, S. uniflora grandiflora.
Wahlenbergia (Edraianthus) serpyllifolia major.

Bulbous Plants.—Many are most suitable for the Alpine House. Some of the best include :—

Chionodoxa sardensis.
Crocus biflorus, C. Sieberi.
Cyclamen neapolitanum, C. neapolitanum album, C. repandum.
Fritillaria aurea.
Galanthus cilicicus.
Iris histrioides, I. Vartani.
Muscari azureum, M. botryoides album.
Narcissus Bulbocodium, N. cyclamineus, N. triandrus albus.
Puschkinia libanotica.
Scilla bifolia.
Triteleia (Milla) uniflora.
Tulipa Batalinii, T. pulchella.

General Culture. — For growing alpines indoors it is best to use pans of 6–10 ins. in diameter. The smaller pans will accommodate single specimens, such as *Primula denticulata, P. Winteri, Saxifraga longifolia,* and similar plants. In the larger pans, three or four plants

such as the Kabschia Saxifrages may be planted, and small pieces of rock placed in as divisions between the plants; these are beneficial and help the appearance of the pan on the whole. Most plants will flourish in good gritty soil, in well-drained pans. Saxifrages like a little limestone grit in the compost. For plants which like peat it is wise to use the best brown fibrous.

During the growing season abundance of water is necessary, but stagnation of the soil must be avoided. During the winter the plants need very little water. Saxifrages may be grown in the house all the year round, and when not in bloom look quite interesting; most of the other plants may be placed outside in a sunny position when not in bloom, excepting the Primulas, which like shade. During October, place all plants in cold frames, and from here transfer to the house as the blooming season approaches. Bulbs must be potted up as soon as received, and the pans stood up to the rims in ashes, till growth commences, when they should be placed on the shelves in the house without delay. With a little practice, neat pans are made up, but plants of the Aubrietia and Arabis type will be banned, since there is enough material amongst the choicer alpines that will always keep the house cheery and interesting.—D. L.

ALPINE PINK (*Dianthus alpinus*).—See *Dianthus*.

ALPINE PLANTS DISLIKING LIME.—See Rock and Alpine Plants in *Lime Haters*.

ALPINE POPPY (*Papaver alpinun*).—See *Poppies: Rock Garden Species*.

ALPINE ROSE—The same as Rose des Alpes.

ALPINE SEA HOLLY (*Eryngium alpinum*).—See *Eryngium*.

ALPINE STRAWBERRIES. — See *Strawberries*.

ALPINE WALL-FLOWER (*Cheiranthus alpinus*).—See *Cheiranthus*.

ALPINE WINDFLOWER (*Anemone alpina*). — See *Anemone: Rock Garden Species*.

ALPINE WOODSIA (*Woodsia alpina*). —See *Ferns and Fern Gardening*.

ALSIKE CLOVER (*Trifolium hybridum*).—See *Trifolium*.

ALSINE.—Now included in the genus *Arenaria*.

ALSTROEMERIA (Herb Lily and Peruvian Lily. Nat. Ord. Amaryllidaceæ).—This is a rather small group of hardy and half-hardy tuberous-rooted plants some of which are valuable for garden decoration, while others make nice plants for pots in a cool greenhouse or conservatory.

Propagation.—The tuberous roots may be divided in spring and replanted in light warm soil. Alstroemerias are also readily increased by seeds, which should be sown either in autumn or early spring in a warm greenhouse in pots or pans of light well-drained open soil. The seedlings when large enough to be handled should be pricked out and grown on under glass until May, when they should be gradually hardened off and finally planted out in their permanent positions in June if of a hardy sort, if only half-hardy they should be "potted on."

Cultivation. — The hardy Peruvian Lilies require a light rich sandy soil. If the natural soil of the garden is very stiff and cold, it is worth while taking it out to a depth of 2 ft. and replacing it by a mixture of leaf-mould, sand, old rotten manure, and light loam, all mixed together. Once a clump is established it should not be disturbed for some years, as none of the family like removal oftener than is necessary. The best of the half-hardy or indoor varieties is *A. pelegrina* (or *peregrina*), the

Lily of the Incas. It is necessary to grow this in pots in most parts of the British Isles. A compost made up of leaf-mould, light loam, and sharp sand will suit this and all the species and varieties that must be grown in greenhouses and cold frames.

Varieties.—Of these the following are undoubtedly the best:—

Alstroemeria aurantiaca. — An orange-red sort and one of the best plants we have for herbaceous borders. It is excellent for cutting, and blooms from June to August. Its height is 3 ft.

A. chilensis.—A July blooming species with flowers of soft shades of rose, red, pink, and pale yellow, with darker marking. Height, 2 ft.

A. haemantha (Syn. *A. pulchella*). —This is a half-hardy species with long narrow tubular crimson flowers tipped with green. It blooms freely throughout the summer, and averages 3 ft. in height.

A. pelegrina (Lily of the Incas). —This is only half-hardy, but is a good pot plant for a cool greenhouse. The type has pretty pinkish flowers, spotted with red-purple, and blooms in July. *A. p. alba* has pure white flowers which are very beautiful. Both are excellent for cutting, and average 1–1½ ft. high.

A. pulchella.—Syn. *A. haemantha*, which see.—J. J. & E. T. E.

ALTAI PRIMROSE (*Primula altaica* or *P. vulgaris Sibthorpii*).—See *Primula.*

ALTERATION OF CHARACTER OF GARDEN, THE LAW ON. — See *Gardening Law.*

ALTERATIONS.—See *Garden Alterations.*

ALTHAEA (Hollyhock. Nat. Ord. Malvaceæ).—This is a genus of hardy annuals, biennials, and perennials of very easy culture. The first section being unimportant, we have decided to omit it. The biennials are raised and treated in the usual way for hardy or half-hardy biennials, while the culture of the perennial species are fully described in our article on *Hollyhock*, also under that name and under Mallow in our article on *Medicinal Herbs.*

Biennial Species.—We recommend the following:—

Althaea caribæa.—This is by some considered a variety of *A. rosea* described in the next section, but has many distinctive characters. It bears large solitary rose flowers with a yellow base from July onwards, and grows about a yard in height.

A. ficifolia.—This bears pretty yellow or orange flowers from July to August, and grows about 2 yds. in height.

A. Sieberi.—This bears purple flowers about the same time as *A. caribæa*, and grows 3–5 ft. in height.

Perennial Border Species.—We recommend the following:—

Althaea cannabina.—This and its variety *narbonensis* bear purplish flowers from July to August, and average 4–7 ft. in height.

A. officinalis (Marsh Mallow).—This, referred to under Mallow in our article on *Medicinal Herbs*, bears pale rose flowers from July to August, and averages 4–5 ft. in height.

A. rosea (Common Hollyhock).—This is the parent of the garden Hollyhocks, hybrids of which are given in our article on *Hollyhock.* The type bears red flowers from July to September, and grows 4–8 ft. high.

See also Hollyhock and Mallow in *Medicinal Herbs.*

ALUM ROOT.—See *Heuchera.*

ALYSSON.—See *Alyssum.*

ALYSSUM (Madwort. Nat. Ord. Cruciferæ).—This genus contains

many plants which are extremely popular for spring bedding or for the adornment of the rock garden. All are dwarf, and most of them are perennial, but one species is annual.

A. maritimum (Syn. *Koeniga maritima*).—This, known as SWEET ALYSSON or SWEET ALYSSUM, rarely exceeds 4 ins. in height; it has small, deep green leaves and is of spreading habit. Its flowers are white, honey-scented, and very small, but so freely produced that the plants are a mass of snowy white in late spring and summer. Sow seeds in March, in light soil in the open. If a dwarf compact variety is grown, it is best propagated by means of cuttings in spring or autumn. *Little Dorrit, minimum* and *compactum*, are varieties specially suitable for bedding. If these are clipped closely as soon as the first crop of blooms fade, they will flower freely a second time the same year. The common type grows wild abundantly in some parts of southern England and on the cliffs in the Channel Islands, but it is considered to be a garden escape, and not a native species.

Rock Garden Species. — About half a dozen perennial species, including all the dwarfer kinds, are suitable and thrive in well-drained sandy loam in a sunny position. Some may be increased by division of roots in autumn or spring, and all by cuttings in July or by seeds in heat in March.

Alyssum alpestre.—Forms a carpet of hoary leaves on very short stems. Flowers bright yellow. Site sunny. Soil gritty. Flowering Period, May to June. Height, 3 ins.

A. argenteum.—This is of shrubby habit. Leaves entire, silvery. Flowers bright yellow. Site sunny. Soil loamy. Flowering Period, May to June. Height, 1 ft.

A. montanum.—A dwarf carpeting plant with hoary leaves. Flowers large bright yellow, sweetly scented. Site sunny. Soil sandy loam. Flowering Period, May to July. Height, 3 ins.

A. saxatile (ROCK MADWORT).—A tufted plant, with sub-shrubby stems. Leaves evergreen, hoary. Flowers rich yellow in masses. Site sunny. Soil gritty or loamy, well-drained. Flowering Period, April to June. Height, 9 ins.

A. saxatile citrinum. — A pale yellow sort.

A. serpyllifolium.—Like *A. alpestre* in habit, but smaller in all parts. Flowers bright yellow. Flowering Period, May to June. Height, 3 ins.

A. spinosum.—This forms a dense bush of spiny woody branches. Leaves small, hoary. Flowers white. Flowering Period, June to August. Height, 1 ft.

AMALGAMS. — See *MERCURY COMPOUNDS*.

AMARACUS.—Now included in the genus *ORIGANUM*.

AMARANTH.—Another name for *LOVE LIES BLEEDING*.

AMARANTUS.—See *LOVE LIES BLEEDING*.

AMARYLLIS (BELLADONNA LILY. Nat. Ord. Amaryllidaceæ).—Only one species, the best from the ordinary man's point of view, is now included in this genus of half-hardy bulbs. This, *A. Belladonna*, is available in many colour forms such as pink, rose, flesh-colour, crimson, and white. It blooms from June to September, and averages 2 ft. in height. Culture is fairly simple; planting outside should only be done in warm sheltered sites where the soil is light, deep, and moderately rich. The bulbs should be set 5 or 6 ins. deep and protected with litter in the winter. They are handsome pot subjects requiring none but the usual treatment, though plenty of water is necessary when they are flowering.

It may be well to add that there are many hybrids requiring stove treatment. A fair proportion of these are now put under the genus *Hippeastrum* by botanical experts, though the last is now divided into very numerous sub-genera such as Asclemia, Lais, Macropodastrum, etc. etc., which include the majority of the Amaryllises of to-day. The Kew authorities refer a number of the species to the genera *Crinum*, *Ixiolirion*, *Sternbergia*, and *Zephyranthes*, all of which receive separate treatment under these names. As stove species are excluded from the present edition of this work we are not describing any here.

New Variety.

Amaryllis Belladonna speciosa purpurea.—A fine sort, with the outer half of its petals deep purple.

AMATEUR GARDENER.

Opinions differ as to the exact meaning of the term "amateur gardener." We regard it to include all those who garden for the love of the thing and not for profit. Amateurs often have to employ a professional gardener to help them, but some regard those who employ gardeners as outside the meaning of the term—which is obviously absurd. Where, however, the garden is run for both pleasure and profit, *i.e.* subjects are grown for the market, the holder of such a garden is no longer an amateur.

AMBLIRION.—Now included in the genus *Fritillaria*.

AMBLYOLEPIS.—Now included in the genus *Helenium*.

AMBROSIA (Nat. Ord. Compositæ). Two species of this, *A. artemisifolia* and *A. trifida* (Syn. *A. integrifolia*), are sometimes offered in catalogues as "choice plants with Aster-like flowers." Both are subjects to be avoided, the latter specially so as it is the well-known Great Ragweed, a ubiquitous plant bearing coarse yellow flower heads most of the summer on plants 1–3 ft. high.

AMELANCHIER.—For the best species see *Shrubs*.

AMERICAN ARBOR VITAE (*Thuya occidentalis*).—See *Trees*.

AMERICAN ASPEN (*Populus tremuloides*).—See *Trees*.

AMERICAN BARBERRY (*Berberis canadensis*).—See *Shrubs*.

AMERICAN BLADDER-NUT (*Staphylea trifolia*).—See *Shrubs*.

AMERICAN BLIGHT.—See Woolly Aphis in *Insect Pests*.

AMERICAN CHESTNUT (*Castanea dentata*).—See *Trees*.

AMERICAN COWSLIP.—See *Dodecatheon*.

AMERICAN CRAB APPLE (*Pyrus coronaria*).—See *Trees*.

AMERICAN CRANBERRY (*Oxycoccus macrocarpus*).—See *Shrubs*.

AMERICAN CRESS.—See *Cress* and *Winter Cress*.

AMERICAN DROP-SEED GRASS.—See *Muehlenbergia*.

AMERICAN ELM (*Ulmus americana*). See *Trees*.

AMERICAN GOOSEBERRY MILDEW. See under Gooseberry Mildew in *Diseases of Plants*.

AMERICAN HOLLY (*Ilex opaca*).—See *Holly*.

AMERICAN HORNBEAM (*Carpinus americana* and *C. caroliniana*).—See *Trees*.

AMERICAN HORSE MINT (*Monarda Punctata*).—See *Monarda* and *Potherbs*.

AMERICAN IPECACUANHA (*Gillenia stipulacea*).—See *Gillenia*.

AMERICAN LARCH (*Larix occidentalis* and *L. pendula*).—See *Trees*.

AMERICAN MOUNTAIN ASH (*Pyrus americana*).—See *Trees*.

AMERICAN PLANTS.

One of the most interesting sections of plants that has come to us from America is the Ericaceous, and many of these are familiar objects to all who take an interest in gardening. We are in-

debted to the infusion of the strain of American Rhododendrons for the bulk of the garden hybrids of this fine family of evergreen flowering shrubs ; and although in themselves the native forms of these plants are not very attractive, our garden would suffer materially were it not for the hardy strain that has been made available by the crossing of the American native species with the Himalayan and other species, which have produced the fine garden hybrids so well known all over this country. Seen in their native habitat the American Rhododendrons have a charm of their own, and through the Eastern States, and running south for a considerable way, they form one of the predominant undergrowths, and in Tennessee and the Carolinas when full blown are a fine sight.

In conjunction with them are other plants of the same family, and amongst the most showy is the *Kalmia latifolia*, or, as the American calls it, the Mountain Laurel, or sometimes the Calico Bush.

In the Arnold Arboretum at Boston there is a fine border of these plants originally gathered from the woods, which presents a gorgeous display when in full bloom. Other forms of Kalmia dominate certain districts. The writer has walked through miles of *Kalmia angustifolia*, commonly called the Sheep Laurel, in New Brunswick, where it forms, in conjunction with *Kalmia glauca*, *Ledum palustre*, and the Native Azaleas, the scrub growth upon " The Barrens " of this territory. *Ledum palustre* and *L. latifolium* are two good subjects. The former is called The Labrador Tea plant, and, as its name implies, extends to the far North. A noticeable feature of these is the scent derived from the foliage when crushed or bruised, the leaves emitting a pungent odour.

There is also the dwarf *Ledum buxifolium*, a charming little plant seldom seen in this country now, although at one time quite plentiful.

The writer cannot understand why these plants are not more used in gardens where Ericaceous plants thrive, as at the time of blooming they give an excellent show, and are always attractive plants when doing well. The Andromedas, with which one couples the Leucothoes, are also beautiful plants and well worthy of a position in any garden, and the best of these, as a garden plant, is undoubtedly *Andromeda floribunda*, but *A. speciosa* is a very attractive plant, as also is *A. Catesbaei*, the latter being a valuable plant for garden purposes, thriving well in the shade, and during the winter the foliage assumes different bronzy hues which are most attractive.

Probably one of the most attractive plants in the American woods is the American Dogwood (*Cornus florida*), both white and pink flowered, the latter not being so common, but a most beautiful form. In the spring the woods are alive and gay with the blossom, and in the autumn the brilliant red fruit is one of the dominant features, and, in addition, the foliage is one of the most attractive, so far as autumn colouring is concerned. It seems a great pity that such a beautiful tree should not be more successful in this climate. There are, however, a few good examples of it in England.

The Tree Andromeda (*Oxydendron arboreum*), also called *Andromeda arborea*, is also a most striking tree, attaining a height of some 50 ft., and when in flower during July and August is a most lovely sight, and also has the advantage of turning to beautiful tints in the autumn.

Another plant family that cannot be passed over in discussing American subjects is the Vaccinium, and from a garden point of view the plants are valued both for their fruits and autumnal colouring. Those who have been in America will certainly remember the Vaccinium family with gratitude if they happen to have encountered Blueberry pie, which is one of the standing dishes during the autumn months in the Northern States. *Vaccinium corymbosum* is one of the most brilliant of the autumn colouring plants, and is widely distributed as a scrub plant throughout New England. *Vaccinium pensylvanicum* is also one of the most striking features of ground-covering plants, and on poor land, where it is so frequently met with, the brilliance of its foliage is unsurpassed in the autumn season.

In connection with autumn tints it is impossible to pass over the Oaks, Maples, and Liquidambar without comment, and these trees in their many varieties give us all the brilliant reds of autumn, which, mixed with the lovely golden tints of the Tulip Tree, once seen can never be forgotten, while the undergrowth, consisting of many brilliant shrubs, some of which have already been noticed, together

with the Stag's Horn Sumach (*Rhus typhina*), *Viburnum cassinoides*, *Pyrus nigra*, *Pyrus melanocarpa*, and the lovely Sassafras, assists in the gorgeous medley of colour. One striking feature, which the writer always attributes to the climate, is the well-doing of hard-wood shrubs and trees and the prolific bearing of fruit.

The spring season in America does not start until winter is completely past. There are rarely late frosts, and all the flowering trees and shrubs develop without check. The ripening influence of the autumn weather enables complete maturity to be established, and from year to year there is invariably a great crop of berries and fruits of all kinds.

A visit to the Arnold Arboretum during the winter season is a great treat to any lover of berry-bearing trees. The many species of Hawthorns which Professor Sargent has collected from all parts of the States may be seen in full fruit, and their brilliant-coloured berries are one of the features of the landscape at that season. The limited space available does not admit of anything further than touching on the fringe of all the many beautiful wild flowers and so on that are encountered while travelling through the States. Spring, summer, and autumn the woods and wild fields are ablaze with colour, and are a constant source of interest.

With very few exceptions the American trees and shrubs are capable of being grown in any part of the British Isles, and those which do not succeed are for the most part from the North-Eastern States, and it is probably due to the fact that our winters are usually too soft, and the effect of this condition is to keep the plant in a constant desire to grow, instead of ripening off in the autumn and hardening up for the rigorous winters they have to withstand.

It is a curious fact that many of the trees and shrubs of North America from West of the Rocky Mountains are much more easily grown in England than in the Eastern States, and typical instances are to be found in the fine Conifers seen here growing to perfection, such as the Wellingtonia, Lawson's Cypress (*Cupressus lawsoniana*), *Thuiopsis borealis*, and perhaps the best of all the Douglas Fir, none of which are good trees in the Eastern States and seldom seen, except in collections of enthusiasts.

English gardens are much indebted to America for many interesting and beautiful shrubs, and without giving an exhaustive list one might place the family of Ericaceous plants as the most easily grown and perhaps giving the greatest effect, Rhododendrons, Kalmias, Ledums, Vacciniums, and others being as much at home here as in their native homes.—F. G. W.

[Regarding the cultivation of American plants an open soil will suit them well, even if it may be inclined to be on the poor side. Peat is an addition to the soil which most American plants appreciate; this can be dug in when the land is being prepared, and again with a little rotted manure at the close of each winter season. Many American plants abhor lime, and this fact should be remembered when making ready for planting.—EDITOR.]

AMERICAN RED PLUM (*Prunus americana*).—See TREES.

AMERICAN SPANISH OAK (*Quercus falcata*).—See TREES.

AMERICAN SPINDLE TREE (*Euonymus americanus*).—See CLIMBING AND TRAILING PLANTS.

AMERICAN WEEPING WILLOW (*Salix purpurea pendula*). — See TREES.

AMERICAN WHITE OAK (*Quercus alba*).—See TREES.

AMIANTHIUM.—Now included in the genus *Zygadenus*.

AMMOBIUM. — See EVERLASTING FLOWERS.

AMMONIA AND AMMONIUM COMPOUNDS.—If the gardener looks down the list of a horticultural sundriesman he will see figuring in places of honour in the fertiliser section compounds prefixed by the word Ammonia or Ammonium. Thus we have ammonia or ammonium carbonate, chloride, nitrate, phosphate, and sulphate. If the gardener asks himself the question, "What is ammonia?" he comes to the unsatisfactory conclusion that it is a gas quite invisible to the naked eye but strangely assertive of its presence as regards the naked nose. If, however, the gardener asks the same

question of a chemist, this gentleman will reply that ammonia is a compound of nitrogen and hydrogen, that its formula is NH_3, that its molecular weight is so-and-so, that its density is something else, and that to all intents and purposes it behaves by uniting with acids and forming salts, just as if it were any one of the well-known metals, such as cadmium, calcium,[1] iron, lead, nickel, potassium, sodium, tin, or zinc. For our purpose in the present article we shall consider it as if it were a metal, since it will be simpler for us to do so rather than enter into details concerning it being a "bi-elementary compound."

The pure substance is difficult to obtain and has little practical value in the garden. Dissolved in water, however, it is useful. This liquid is really a weak solution of ammonium hydroxide. As far as we are aware, the pure hydroxide has never yet been isolated, since it decomposes into ammonia and water. "Strong" ammonia has a limited application in the garden, since the vapour burns the foliage. It is said, however, to be an effectual means of slaying the tiresome bean aphis. We understand the method adopted is to pass swiftly along the bean rows holding the spout of an uncorked bottle of ammonia close to the aphis-covered stems meanwhile, and after passing down the rows twice, the aphis are easily syringed off with warm water. A very weak solution of ammonia has been found of slightly advantageous effect as a fertiliser to leaf-bearing vegetables, but it is little used. See also *Chemistry for Gardeners*.

[1] Most gardeners will never have seen metallic sodium or potassium. It is unlikely that they will have seen metallic calcium either, though it was made by the ton certainly up to the beginning of the war, by electrolysis of fused calcium chloride. —Editor.

AMMONIUM CARBONATE is a compound of very little importance. It can be used, as can also the better known

AMMONIUM CHLORIDE (*sal-ammoniac*), as a winter or early spring dressing for heavy land to which it is desirable to apply some richly nitrogenous manure. One ounce to the square yard will be enough.

AMMONIUM NITRATE is one of the very best stimulants, and were it cheaper its application would be wide. We consider there is nothing like it for stimulating leaf-crops. It is certainly the fastest fertiliser that we know of.[2] Owing to the extraordinary amount of nitrogen it contains, the gardener should be most careful never to apply it in too great a quantity or to plants capable of getting nitrogen for themselves from the air, as can all plants of the order Leguminosæ. One-fourth ounce to the gallon of water very occasionally will be quite enough to apply; to give more would be to court disaster.

AMMONIUM PHOSPHATE.—This is more use to the exhibitor than to the practical gardener. It induces high quality into both flowers and vegetables; and exhibitors of Sweet Peas and many florists' flowers could hardly do without it. One-fourth ounce per gallon of water very occasionally can be used as a stimulant, but for exhibition purposes it can be used more often. It can be scattered on the ground at the rate of $\frac{1}{4}$–$\frac{1}{2}$ oz. per 9 sq. ft., and well hoed in.[3]

AMMONIUM SULPHATE.—This

[2] Ammonium Nitrate is quicker in its action than is nitrate of soda or even nitrate of potash. It is probably the fastest fertiliser we shall ever have. —Editor.

[3] Care should be taken when purchasing to get the pure substance.—Editor.

is probably the most popular as well as the most widely used of all ammonia compounds. Almost every gardening book informs us glibly that it is made in the manufacture of coal-gas. The ammoniacal liquor there produced is neutralised with chamber acid (dilute sulphuric acid), and the compound "sublimed." Its manufacture, however, is of little interest to the average gardener; what is more important to him are its uses and its purity. Samples of sulphate, nitrate, and phosphate of ammonia in water should be tested with blue litmus paper, and should the solution turn it red, the samples should be rejected as unfit for use.

Sulphate of ammonia is a quick stimulant but milder than nitrate of soda. One ounce of it can safely be put into each gallon of water, but the liquid should be used only for those plants or crops in which it is desired to produce much leafage. Sulphate of ammonia should never be used for potatoes, neither for Jerusalem artichokes; in the first case it will produce a tangled undergrowth of haulm, and in the second the main stem of the artichokes will shoot up heavenwards until it disappears almost completely from view! In both cases the crop of tubers resulting will be hardly worth digging.

Test for Ammonia Compounds.—The five above-named salts of ammonia are all of them very easily adulterated with various other cheaper chemicals. This adulteration continues unchecked in spite of the Fertilisers and Feedings Stuffs Act. However, there is a simple test for adulteration which every gardener can make and should make for himself prior to the purchase of a large consignment. A small quantity of any or all the compounds is put on a hot shovel and the shovel put into the fire again. If unadulterated there will in a few minutes be nothing left on the shovel. If, however, a residue amounting to half or even a quarter of the tested sample remains, that sample is not pure, and consequently should be rejected, as the impurities, whatever they may be, are almost certain to prove injurious to plant life.—E. T. E.

AMMONIACAL COPPER CARBONATE.—This is sometimes used as an insecticide. The proportions are

Copper Carbonate.	½ lb.
Ammonia . .	1 gal.
Water . .	90 gals.

The liquid should be applied with a syringe in the ordinary way.

AMMONIACAL LIQUOR.

This consists chiefly of ammonia, and if available near at hand should be largely used in the garden. Vegetable refuse which is rotting down may be thoroughly soaked with it once a week until it is dug in, and the value of the latter as manure will certainly be doubled if such a practice is adopted. Heaps of road manure, the fertilising value of which is comparatively poor, may with great advantage have frequent soakings of this liquid, and after decomposing down for a few weeks their value will be enormously increased. Immediately after such a soaking the heap or heaps should be thoroughly well dusted with powdered gypsum or covered with soil to prevent the escape of the Ammonia. A very impure form of this known as Gas Tar Water or Gas Liquor has a strong pungent odour and is of some use as a soil insecticide. A quart of this in 10 gals. of water will, it is said, completely clear any plot of pests if a thorough soaking of the liquid is given.

AMMONIUM COMPOUNDS.—See *Ammonia and Ammonium Compounds.*

AMMOPHILA (MARRAM GRASS. Nat. Ord. Gramineæ).—This is an unimportant genus of grasses to which little attention need be paid by gardeners. The best known species is *A. arundinacea* (Syn. *A. arenaria*), known as SEA MATWEED, used for binding sand in sand dunes together on the North Wales coast, North-West of England, and other districts.

AMOOR PINK (*Dianthus dentosus*).—See *DIANTHUS*.

AMORPHA.—For the best species see *SHRUBS*.

AMOUNT OF SEED REQUIRED.—See *SEED : AMOUNT REQUIRED*.

AMPELOPSIS.—See under VITIS in *CLIMBING AND TRAILING PLANTS*.

ANACHARIS.—Now included in the genus ELODEA.

ANACYCLUS (Nat. Ord. Compositæ).—This is an unimportant genus of hardy annuals not of much garden value. For descriptions of the somewhat numerous species larger works should be consulted.

ANAGALLIS (PIMPERNEL. Nat. Ord. Primulaceæ). — Even the native Pimpernel, *A. arvensis*, is a popular plant, and one which has been known also as the POOR MAN'S WEATHER GLASS for long past. Most of the species in cultivation are of annual duration and have been improved by selection and cultivation. All those named below are easily raised from seeds sown in a warm position in March or April :—

Anagallis arvensis (Syn. *A. phoenicea*).—This has red flowers, but its variety *caerulea*, with blue flowers, is a better garden plant. Both bloom from June to August, and average 12 ins. in height.

A. latifolia is now referred to *A. arvensis* and is synonymous with *A. indica*, but a plant grown under these names is a blue-flowered trailer which blossoms throughout the summer.

A. linifolia (Syns. *A. collina* and *A. Monelli*).—This was formerly more extensively grown than now. It has flax-like leaves clothing its slender stems and surmounted by clusters of brilliant blue flowers, each half an inch across. *Grandiflora* is a name given to dwarf, large flowered, variously coloured varieties of this species. One member of this group, named *Willmoreana*, is 6 ins. high, and has bright purple-blue flowers with yellow eye. Other good varieties are *Napoleon III* (maroon); *Parksii* (red); *Phillipsii* (Syn. *A. Brewerii*) (red); and *sanguinea* (ruby). They are not often met with nowadays.

Creeping Species. — One species cannot very well be passed over without mention. This, *A. tenella*, the pretty little BOG PIMPERNEL, is a perfectly hardy subject bearing pink flowers in July, and averaging 3 ins. high. Once planted in the rock garden it will spread rapidly, so must not be set near choice subjects.

ANALYSIS OF PLANT ASHES. — See *ASHES OF PLANTS : ANALYSIS OF*.

ANAPELTIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

ANASTATICA. — See *RESURRECTION PLANT*.

ANBURY.—See under CLUBROOT in *DISEASES OF PLANTS*.

ANCHISTEA.—Now included in the genus WOODWARDIA, for which see *FERNS AND FERN GARDENING*.

ANCHOR PLANT (*Colletia cruciata*).—See *SHRUBS*.

ANCHUSA (ALKANET. Nat. Ord. Boraginaceæ). — Of the large number of species which have been described in this genus some few are annuals—these we may neglect as being unimportant—others are half-hardy biennials, while still others are among the most useful of hardy herbaceous perennials of very easy

culture. All the species are good bee plants, but none are desirable for use as cut flowers.

Biennial Species. — These being half-hardy require to be sown in boxes or pans in a cold frame in the spring-time and potted up when the seedlings have made a few rough leaves. They should be shifted into larger pots as they require room, and in October transferred to a greenhouse from which frost is just excluded, from which they may be safely planted out in a sunny position the following May. The best species is :—

Anchusa capensis. — This bears blue flowers in July on stems 18 ins. high.

Perennial Border Species.—These require the usual treatment for hardy perennials, and most are handsome border plants forming large bushes which need efficient staking. They may be raised from spring or summer sown seeds, or propagated by root cuttings in July. As they do not stand the winter well in cold wet districts, planting is best postponed till March. If the plants are cut down immediately after flowering and well looked after in the way of water and manure, they very often bloom again in September or October. We recommend the following species :—

Anchusa arvensis (Tausch).—Syn. *A. officinalis*, which see.

A. azurea.—Syn. *A. italica*, which see.

A. Barrelieri.—This bears pretty blue flowers from July onwards, and averages half a yard in height.

A. italica (Syn. *A. azurea*).—This is quite the most popular species of all with its glorious bright blue flowers in June on plants 3–5 ft. in height. The best variety of this is *Dropmore*, often known as the DROPMORE ALKANET, a bright blue, unspeakably lovely and quite impossible to describe. Other good sorts include : *Lissadell Variety* (clear sea-blue) ; *Opal* (pale sky-blue) ; *Perry's Variety* (rich dark blue) ; *Picotee* (white, with blue margins) ; and *Pride of Dover* (pale opal blue). All these bloom about the same time as the type and average a similar height.

A. myosotidiflora.—This is a pretty blue sort suitable for the rock garden. It blooms from July to August, and averages about 9–12 ins. in height.

A. officinalis (Syn. *A. arvensis*, Tausch).—This, the COMMON ALKANET, with its blue flowers in August, is more suitable for the wild garden or shrub border than for the perennial parterre. It grows about 2 ft. in height.

A. sempervirens. — This bears bluish flowers from July onwards, and averages 1–2 ft. in height.

[The names of the plants formerly classed as Anchusas, but now included by the Kew authorities in other genera, are purposely omitted from the present article.—EDITOR.]

ANCISTRUM.—Now included in the genus *ACAENA*.

ANDROMEDA.—For the best species see *SHRUBS*.

ANDROPOGON (BEARD GRASS. Nat. Ord. Gramineæ).—This is an unimportant genus of grasses of little garden value. They are easily grown in a warm corner in the wild garden. Larger works should be consulted for lists and descriptons of species, etc.

ANDROSACE (Nat. Ord. Primulaceæ).—**Annual Species.**—In this genus of exquisitely beautiful alpine plants there are a few which, if not strictly annuals, rarely flourish unless treated as such. The Persian *Androsace filiformis*, the European *A. maxima*, and the Siberian *A. lactiflora* (Syn. *A. coronopifolia*)

may be referred to in this connection, and the last named is the best.

Culture.—Sown in autumn and protected during the winter by an unheated frame, plants of *Androsace lactiflora* should be planted out in spring on a sunny ledge in the rock garden. A mixture of peat, leaf-mould, sand, and limestone chips should be provided, and if the plants are set 4–5 ins. apart so as to make a little colony, the effect will be very beautiful in early summer when these 6-inch high gems carry their pure white flowers above the rosettes of smooth leaves. Self-sown seedlings will succeed in positions where they do not suffer from the dampness of our winter, but it is always a safe plan to protect a few plants in case of accidents. Both *Androsace filiformis* and *A. maxima* bear white flowers and average 6 ins. in height. *A. lactiflora*, which bears bluish-white flowers, resembles *A. lactea* in habit (see below), and is of the same height as the two last named.—C. H. C.

Rock Garden Species.—There are a large number of species, but many are difficult to cultivate. About a dozen may be considered suitable for the ordinary rock garden. Most of these will thrive in well-drained gritty soil in sunny positions or on rocky ledges. They are propagated by division in autumn or spring, cuttings in July, layering in summer, or seeds in March, and in wet districts require the protection of a square of glass from October to March.

Androsace arachnoidea.—A tufted plant, with silvery woolly leaves in small rosettes. Flowers white. Site sunny. Soil gritty and peaty. Flowering Period, June to July. Height, 3 ins.

A. carnea.—This produces dense mats of bright green foliage in tufts. Flowers blush-pink in heads. Site half-shade. Soil grit and peat. Flowering Period, June. Height, 3 ins. There is also a variety with white flowers.

A. Chumbyi (Syn. *A. sacramentosa* x *villosa*).—A free-growing species with silky leaves in rosettes on short stolons. Flowers rosy-pink in umbels. Site sunny. Soil gritty. Flowering Period, May to June. Height, 4 ins.

A. foliosa.—A robust species, with long grey-green leaves in tufts. Flowers rosy-lilac in large umbels. Site sunny. Soil limestone. Flowering Period, May to August. Height, 6 ins.

A. lactea.—Leaves long, pale green, and in rosettes. Flowers white with yellow centre. Site shade. Soil limestone. Flowering Period, June to August. Height, 6 ins.

A. lactiflora (Syn. *A. coronopifolia*).—A biennial species resembling the above in habit. Leaves broader. Flowers bluish-white in large umbels. Site half-shade. Soil gritty. Flowering Period, June to July. Height, 6 ins.

A. Laggeri.—This forms wide mats of bright green foliage. Leaves narrow. Flowers rosy-pink. Site half-shade. Soil gritty and peaty. Flowering Period, March to May. Height, 3 ins.

A. lanuginosa.—This produces long trailing branches clothed with silvery white leaves. Flowers rose-colour in terminal umbels. Site sunny. Soil gritty. Flowering Period, June to September. Height, 6 ins.

A. l. oculata (Syn. *A. Leichtlini*).—Flowers white, with crimson eye. Plant otherwise similar to the above.

A. sarmentosa.—This forms broad patches with rosettes of pale green, silky, hairy leaves at the end of stolons. Flowers bright rose, in large umbels. Site sunny. Soil gritty. Flowering Period, June to August. Height, 4 ins.

A. sempervivoides.—Leaves in

rosettes like a Sempervivum. Flowers rosy-purple. Site half-shade. Soil gritty. Flowering Period, May to June. Height, 3 ins.

A. villosa.—This produces small rosettes of densely woolly leaves in loose clusters. Flowers pale rose with yellow centre, sweetly scented. Site sunny. Soil gritty. Flowering Period, June to July. Height, 3 ins.

A. villosa Chamaejasme (Rock Jasmine).—Flowers open pure white and gradually become blush-pink, otherwise similar to the above.

New Species and Varieties.

Androsace ciliata.—This has rose flowers with a crimson eye, and large leaves in rosettes. Its height is 1 in.

A. Laggeri Warley Variety.—This has dark rose flowers with a yellow eye. It is a remarkably free flowering sort.

ANEMIA.—For the best species see *Ferns and Fern Gardening.*

ANEMIDICTYON.—Now included in the genus Anemia, for which see *Ferns and Fern Gardening.*

ANEMONE (Windflower. Nat. Ord. Ranunculaceæ).—Anemones are hardy herbaceous perennials and tuberous-rooted plants ranging in height from 4 ins. to 2½ ft. So widely distributed is the genus that Anemones can be utilised in practically all aspects in the garden, and can be had in bloom nearly all the year round. Propagation is effected by seed, also by division of tubers and of rootstocks.

Culture.—Seed may be sown when ripe or in spring. Division of tubers or of roots should be done in the dormant season. *Anemone japonica* thrives best in a rich cool loam in semi-shade, while *A. Pulsatilla* is partial to an open calcareous medium in full sun. Ordinary garden soil is suitable for most of the other species and varieties.

Uses.—*A. japonica* with its hybrids are useful for providing cut flowers with long stems in the autumn, bloom being obtainable from August to October. The tuberous section, including the Poppy Anemone (*A. coronaria*), and the alpine varieties (see below) are largely used on rockeries and for bedding. Their flowering period ranges from February till July.

Varieties.—The best of *A. japonica* include:—Elegantissima, Kriemhilde, Lady Ardilaun, Mount Rose, Prince Heinrich, and Whirlwind.

Tuberous Section.—The best include:—A. apennina, A. blanda, A. coronaria, A. fulgens, and A. nemerosa.—J. L. G.

Rock Garden Species.—This large family includes Hepatica and Pulsatilla, and nearly a dozen are described below and are suitable for the rock garden. They thrive in deep loamy soil, some in open positions, others in half-shade, and are increased by division of roots in autumn or spring. Most species may also be increased by seeds sown in gentle heat in March.

Anemone alpina (Alpine Windflower).—Leaves much divided and fern-like. Flowers large and pure white. Site sunny. Soil rocky limestone. Flowering Period, May to June. Height, 1–1½ ft.

A. angulosa.—Leaves in rosettes, on long stalks, and three-lobed. Flowers blue, pink, and white. Site half-shady. Soil deep loam. Flowering Period, April to May. Height, 6 ins.

A. blanda (Greek Anemone).—Leaves deeply divided in three on short stems. Flowers deep blue, rose, and white. Site open or half-shady. Soil loam. Flowering Period, February to April. Height, 4 ins.

A. Hepatica (Syn. *Hepatica triloba*). — Leaves three-lobed on short stems. Flowers blue, rose, and white. Site half-shady. Soil loam and limestone. Flowering Period, March to May. Height, 4 ins.

A. montana.—Leaves finely divided. Flowers deep violet and gold. Site open. Soil loam. Flowering Period, June. Height, 1 ft.

A. narcissiflora (DAFFODIL ANEMONE). — Leaves deeply divided. Flowers white in large umbels. Site half-shady. Soil rocky loam. Flowering Period, May to June. Height, 9–12 ins.

A. palmata.—Leaves bright green. Flowers golden-yellow. Site sunny. Soil sandy loam. Flowering Period, April to June. Height, 9 ins.

A. patens.—Leaves finely divided. Flowers delicate purple. Site half-shade. Soil deep loam. Flowering Period, May to June. Height, 12 ins.

A. Pulsatilla (PASQUE FLOWER).—Leaves much divided. Flowers violet with golden stamens. Site open. Soil calcareous. Flowering Period, April to June. Height, 1 ft.

A. sulphurea.—A yellow-flowered *A. alpina.* Soil non-limestone. Flowering Period, May to June. Height, 1 ft.

A. sylvestris (SNOWDROP ANEMONE [1]).—Leaves divided. Flowers sweet-scented, white, and nodding, on long stalks. Site open. Soil loamy. Flowering Period, April to June. Height, 1 ft.—W. I.

NEW SPECIES.

Anemone rupicola.—This bears white flowers with a pink tint on the back, and grows about 12 ins. high.

See also under PASQUE FLOWER in *MEDICINAL HERBS.*

[1] SNOWDROP WINDFLOWER is the Kew name for this.—EDITOR.

ANEMONE RUST.—See *DISEASES OF PLANTS.*

ANEMONOPSIS (Nat. Ord. Ranunculaceæ). — One species of this genus, *A. macrophylla,* a hardy herbaceous perennial not unlike *Anemone japonica,* is well worth growing. It bears lilac-purple flowers in July, and grows 2–4 ft. in height. Its cultural requirements are of the simplest; it merely requires to be planted in good rich loam in November or March, and divided at a similar period once in four or five years.

ANEMOTHECA. — See *PERENNIALS, HALF-HARDY: LIST OF.*

ANETHUM. — Now included in the genus *PEUCEDANUM.*

ANGEL'S TEARS (*Narcissus triandrus*).—See *NARCISSUS SPECIES.*

ANGELICA (Nat. Ord. Umbelliferæ).—This is a small genus of hardy biennials or short-lived hardy perennials more suitable for the water garden or wild garden than for the borders. They grow to a large size, often attaining 10 ft. in height when flowering, and their numerous leaves are quite handsome. They are splendid town garden plants. The stalks may be used for candying, and the plant has a medicinal value. See article on *MEDICINAL HERBS. A. Archangelica,* a favourite species used in confectionery, is now known as *Archangelica officinalis.* See notes on *ARCHANGELICA.*

ANGELICA TREE (*Aralia spinosa*). — See *SHRUBS.*

ANGRÆCUM.—See *ORCHIDS.*

ANGUILLIDÆ. — See EELWORMS in *INSECT PESTS.*

ANGULOA. — For the best species see *ORCHIDS.*

ANIMAL CHARCOAL. — See *CHARCOAL.*

ANIMAL MANURES. — See under GENERAL MANURES in *MANURES.* See also *COW MANURE, HORSE MANURE, PIG MANURE, SHEEP MANURE,* etc.

ANIMATED OR WILD OATS (*Avena sterilis*).—See *Ornamental Grasses.*

ANISEED.—See *Medicinal Herbs.*

ANISETTE.—See Edible Fungi in *Fungi.*

ANISOGONIUM. — Now included in the genus Asplenium, for which see *Ferns and Fern Gardening.*

ANISOPTERIX.—See under Winter Moths in *Insect Pests.*

ANISOTOME.—Now included in the genus *Aciphylla.*

ANISUM.—Now included in the genus Pimpinella.

ANNUAL CLIMBERS.—See *Climbing and Trailing Plants.*

ANNUAL MEADOW GRASS (*Poa annua*).— See *Poa* and *Weeds.*

ANNUAL POPPIES.—See *Poppies.*

ANNUAL SUNFLOWERS.—See *Sunflower.*

ANNUALS FOR ALL PURPOSES.

Annuals may be defined as plants which are raised from seed, bear flowers, and die in the same season, sometimes, but not in all cases, producing or ripening seed. In gardening practice, however, many plants are treated as annuals which are properly biennials or perennials. Others are of annual duration in this country, while in the warmer climate from which they originate they are of perennial habit. Of this class the climbing and dwarf Nasturtiums (*Tropaeolum majus* and *nanum*) are examples.

Hardy Annuals are such as may be sown direct in the open ground in March or April, and will withstand the varying changes of our spring; some, indeed, may be sown in the late summer or early autumn to stand the winter, coming into bloom earlier than the others. By sowing late—up to June—late blooms may be had. Autumn sowing is not advisable in cold and northern districts.

Half-hardy Annuals are of more tender constitution, and to get them sufficiently forward, so that they shall bloom in due course, they must be sown under glass in February, March, or April; or they may be sown out of doors when fear of late frosts is past, but are then later in blooming. [In exposed districts outdoor sowing should be avoided, since frequently the plants fail to bloom.—Editor.]

Greenhouse Annuals are even more tender, and call for more warmth and greater care in the early stages. They are often used for summer bedding, but mainly for conservatory and indoor decoration.

Culture of Hardy Annuals.—As a general rule, these require a sunny position to be seen at their best. The soil should be well dug, and if a moderate amount of manure is given, the results will be finer. Rake the soil smooth before sowing, and in all cases sow thinly. Small seeds need not be covered with more than their own depth of soil; larger ones can have from a quarter of an inch (in the case of, for example, Convolvulus minor) to half an inch (Nasturtiums). [For details of culture, readers are referred to our article on *Annuals, General Culture of.*—Editor.]

Culture of Half-hardy Annuals.—These should be sown thinly in boxes or pots, using a soil composed of fine loam, with a little leaf-mould and sand. Drain the boxes, and having put in the soil to within half an inch of the top, give a good watering, and, when the surplus water has drained off, sow the seed thinly. If it is very small, do not cover it with soil, but merely press it in with a smooth board; for larger seeds, sprinkle a little fine soil evenly over the surface. Stand the boxes in the greenhouse or frame, or, failing these, in a room indoors, and keep them shaded until the seedlings appear,

then give them light and air. As soon as the first pair of leaves are made, prick the young plants out into other boxes or pots, and return them to the frame or greenhouse, giving them full light after a day or two. Water carefully; excess is harmful, and leads to DAMPING-OFF (which see in *DISEASES OF PLANTS*). When they have made sufficient growth they may be potted off singly; and later on they can be hardened off (see *HARDENING OFF*) in readiness for planting out.

CULTURE OF GREENHOUSE ANNUALS.—These should be sown in February or March, and require more heat than half-hardy annuals. Prick them out singly into small pots as soon as they can be handled, and continue to grow them on briskly, shifting them into larger pots as required. If they are wanted for summer bedding, they must be gradually hardened off towards the end of May, preparatory to planting out some time in June.

HARDY ANNUALS FOR BEDS AND BORDERS.

Adonis autumnalis.
Agrostemma Coeli-rosa (Rose of Heaven).
Anchusa capensis.
Argemone mexicana (Prickly Poppy).
Arnebia cornuta.
**Bartonia aurea.*
**Calendula officinalis* (Pot Marigold).
*Calliopsis (also called *Coreopsis*).
*Candytuft (*Iberis*).
Centranthus macrosiphon.
**Chrysanthemum carinatum* and *C. coronarium* (summer flowering).
**Clarkia elegans.*
Collinsia bicolor.
Convolvulus minor.
*Cornflower (*Centaurea Cyanus*).
**Erysimum Perofskianum.*
*Eschscholzia (Californian Poppy).
Eutoca viscida.
Gilia.
*Godetia.
**Gypsophila elegans.*
Hawkweed (*Hieracium*).
*Larkspur (*Annual Delphinium*).
Lavatera trimestris.
Leptosyne Stillmannii.
Linaria maroccana.
Linum grandiflorum.
*Love-lies-bleeding (*Amarantus caudatus*).
Lupine (several species).
Malope grandiflora.
*Mignonette.
*Nasturtium.
*Nigella (Love-in-a-Mist).
*Poppy (Shirley, Carnation-flowered, and Paeony-flowered).
Salvia Horminum.
Saponaria Vaccaria.
**Schizanthus grandiflorus.*
Schizopetalon Walkeri.
Silene Armeria.
*Sunflower (*Helianthus annuus*, etc.).
*Sweet Pea.
*Sweet Scabious.
*Sweet Sultan (*Centaurea*).
Venus's Looking-Glass (*Specularia*).
Viscaria.

FOR EDGING.

Alyssum maritimum (Sweet Alyssum).
Asperula azurea setosa.
Calliopsis (dwarf varieties).
Eucharidium Breweri.
Gilia (dwarf varieties).
Iberis umbellata (dwarf varieties of common Candytuft).
Kaulfussia amelloides.
Leptosiphon.
Limnanthes Douglasii.
Medicago Echinus.
Nasturtium (dwarf varieties).
Nemophila.
Phacelia campanularia.
Platystemon californicus.
Sanvitalia procumbens.
Saponaria calabrica.
Silene pendula.
Sphenogyne speciosa.
Virginian Stock (*Malcomia maritima*).

FOR CARPETING.

Alyssum maritimum (Sweet Alyssum).
Candytuft (dwarf).
Leptosiphon.
Nasturtium (dwarf).
Nemophila insignis.
Phacelia campanularia.
Sanvitalia procumbens.
Silene pendula compacta.

FOR ROCKWORK.

Æthionema Buxbaumi.
Alyssum maritimum (Sweet Alyssum).
Asperula azurea setosa.
Corydalis glauca.
Kaulfussia amelloides.
Leptosiphon.

* Indicates plants useful for cutting.

Limnanthes Douglasii.
Meconopsis heterophylla.
Nemophila.
Sanvitalia procumbens.
Silene pendula.
Sphenogyne speciosa.
Venus's Navelwort (*Omphalodes linifolia*).

FOR SPRING BLOOMING.

Alyssum maritimum (Sweet Alyssum).
**Asperula azurea setosa.*
**Bartonia aurea.*
*Candytuft (*Iberis*).
*Clarkia.
Collinsia bicolor.
**Erysimum Perofskianum.*
*Godetia.
Leptosiphon.
Leptosyne Stillmannii.
Limnanthes Douglasii.
Linaria maroccana.
Nemophila.
Poppy.
Saponaria calabrica.
Silene Armeria and *pendula.*
Sphenogyne speciosa.
Violet Cress (*Ionopsidium acaule*).
Virginian Stock (*Malcomia maritima*).

FOR AUTUMN BLOOMING.

By late sowing many of the annuals already mentioned can be had in bloom in autumn. The following can be relied upon if sown as late as the end of June:—

Alyssum maritimum.
Candytuft (*Iberis*).
Leptosiphon.
Limnanthes Douglasii.
Violet Cress (*Ionopsidium acaule*).
Virginian Stock (*Malcomia maritima*).

Others that will bloom at this season are: Clarkia, Cornflower, Godetia, *Gypsophila elegans*, Lavatera, Malope, Mignonette, Nasturtium, Sweet Pea, Sweet Sultan.

HALF-HARDY ANNUALS FOR BEDDING.

**Ageratum mexicanum.*
Alonsoa Warscewiczii.
**Arctotis grandis.*
Aster (*Callistephus*).
Cacalia coccinea.
Cleome gigantea.
Convolvulus major.
**Cosmos* (Mexican Aster).
Diascia Barberae.
Gaillardia picta.
Helipterum.
Kochia trichophylla (Summer Cypress).
Mina lobata.
Morning Glory (*Ipomoea imperialis*).
*Namaqualand Daisy (*Dimorphotheca aurantiaca*).
*Nicotiana (Tobacco Plant).
Perilla nankinensis.
Phlox Drummondii.
Rudbeckia bicolor.
*Salpiglossis.
Salvia Blue Beard.
**Schizanthus Wisetonensis.*
**Senecio elegans* (Jacobaea).
**Statice sinuata.*
*Stocks.
*Tagetes (African and French Marigold).
Zinnia.

Most of these bloom until autumn.

FOR EDGING.

Ageratum (dwarf).
Arctotis calendulacea.
Brachycome iberidifolia (Swan River Daisy).
Marigold (dwarf French).
Mesembryanthemum crystallinum (Ice Plant).
Nemesia.
Phlox Drummondii.
Pimpernel (*Anagallis*).
Portulaca (Sun Plant).

FOR ROCKWORK.

Arctotis calendulacea.
Brachycome iberidifolia.
Mesembryanthemum album and *M. tricolor.*
Pimpernel (*Anagallis*).
Portulaca.
Sedum coeruleum.

ANNUALS FOR "EVERLASTINGS."

Acroclinium.	*Statice sinuata.*
Helichrysum.	Xeranthemum.
Rhodanthe.	Etc., etc.

These are best treated as half-hardy annuals. See also article on *Everlasting Flowers.*

GREENHOUSE ANNUALS.

Balsam (*Impatiens*).
Browallia.
Celosia (Feathered Cockscomb).
Ricinus.
Solanum Melongena (Egg Plant).
Torenia Bailloni.

W. J. C.

* Indicates plants useful for cutting.

ANNUALS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING.*

ANNUALS FOR SEASIDE GARDENS. See *SEASIDE GARDENS: PLANTS AND TREES FOR.*

ANNUALS: General Culture of.

There are a great many gardeners who tell one they can never succeed in growing annuals, and this fact is astonishing. There is no real difficulty in the way of cultivating most annuals, yet there are a few little points which are essential for success.

Sow Thinly in April.—Unless annuals are sown in the autumn, which to my mind is not to be strongly commended, they should be sown in April, and preferably during the first week.

Previous to this the soil should be dug up and some rotten manure worked in *well down.* This last is important, for the roots of the annuals ought to have to go and find the manure. If possible all the digging should be done more than a month before sowing, to let the soil become quite firm again.

The position where the seeds are to be sown should be lightly raked over, and for Mignonette trodden firm, or the seed may be lost in the air crevices.

It goes without saying that the dwarfest annuals should be sown closest to the edging of the plot, with the taller ones behind. So I pass on to the seed sowing itself. Annuals should mostly be grown in sunny positions.

Sow *thinly*—that is essential. Small seed should be mixed with about ten times its bulk of fine sand or soil, and the whole distributed evenly over the ground. The bed may then be lightly covered with fresh fine soil, and made firm with a trowel. Do not under any consideration apply even a small quantity of fertiliser when sowing, for besides not requiring it, it may be positively harmful to the annuals at this early stage.

Generally speaking, it is best to sow annuals in clumps, and these should be of good size. Clarkias, Godetias, Love-in-a-Mist (*Nigella*), and Shirley Poppies look specially well in clumps.

As soon as the seedlings are an inch or two high, thin rigorously if needed. This thinning must be repeated three or four times if the seedlings come up too thickly. Well-grown specimens of Clarkia, Godetia, or Mignonette want plenty of room—6 ins. apart, finally, is none too much.

Stake Early.—Annuals are quick-growing subjects and are easily broken down by rain, and blown about. Thus ties and stakes should be supplied at an early date. Several sticks can be arranged round the outside of a clump, and bast stretched from one to the others. Sunflowers require a single stake, of course, and it must be a strong one. As the annuals grow give extra ties, and it is very unlikely that they will look anything but tidy and beautiful.

Watering, etc.—Many annuals are very fond of water, and this should be given *liberally* during the summer months. If lawn mowings or old hotbed manure be spread round the roots this will help to conserve the moisture.

Clarkias, Mignonette, and many others may be used for cutting; and cut them with no hesitation. On no account let dead flowers remain on any annual, or it will cease flowering. Cut them off at once as soon as formed: such work might well be done every day, and even then that would not be too often. It is unnecessary to give lists of annuals, as these can be found in the article on *ANNUALS FOR ALL PURPOSES* already given.

This is but a brief sketch of the culture of annuals. In so short an article one cannot do more than give the main points.—E.

ANNUALS, HALF-HARDY: List of. [The following selection of these contains the cream of those in cultivation and will prove useful to many readers.—EDITOR.]

	Inches
Ageratum Heavenly Blue. Slate blue. May to September.	12–24
Alonsoa Warscewiczii. Red, pink. April to September.	9
Amarantus. Red foliage. April to October.	12–24
Anagallis caerulea. Rich blue. May to October.	6
Asclepias Curassavica. Red. June to November.	24
Aster sinensis. Various. July to November.	12–24
Balsam. Various, pink. June to October.	18
Begonia (fibrous-rooted). Crimson, white. June to October.	12
Browallia elata. Blue and white. June to September.	18
Calceolaria. Yellow, red, bronze. Spring, autumn.	12–20
Canna indica. Red, yellow. July to November.	18–36
Carnation semperflorens. Various. July to December.	18
Celosia cristata. Crimson, orange, white. August to December.	10–24
Celosia plumosa. Crimson, yellow, red. August to December.	10–24
Celsia Arcturus. Yellow. June to December.	15
Cheiranthus kewensis. Cream to mauve. July to November.	24
Chrysanthemum Leucanthemum. Various, white. June onwards.	30
Cineraria. Various. Spring and autumn.	15–30
Clianthus Dampieri. Scarlet and black. July to December.	24
Coleus. Foliage various. June to December.	24
Cosmos. Crimson. Yellow, pink. September to December.	18–48
Cuphea miniata. Scarlet. June to October.	12
Cyclamen persicum. Pink, white, crimson. October onwards.	12
Cyperus. Foliage. May onwards.	18
Datura meteloides. White. July onwards.	36
Dimorphotheca aurantiaca. Salmon, orange. June to November.	12
Exacum affine. Mauve. July to October.	[Ins.] 9
Exacum macranthum. Violet. July to October.	18
Freesia refracta. White, various. August onwards.	12
Gilia coronopifolia. Scarlet-crimson. May to October.	36–48
Gladiolus (early flowering). Various. August to September.	30
Gloxinia. Various. August onwards.	10–12
Gomphrena globosa (Globe Amaranth). Various. Everlasting. July to October.	12
Hebenstretia comosa. Orange and white. June to November.	18
Helipterum. Various. Everlasting. July onwards.	12
Hibiscus Manihot. Primrose yellow and crimson. June to September.	40
Impatiens. Orange, red, pink, liliac. June to November.	18
Ipomoea rubro-caerulea. Pure sky-blue. May to October.	Climber
Lantana. Various warm colours. June onwards.	12
Loasa aurantiaca. Orange. July to November.	Climber
Lobelia. Blue, white, crimson. June onwards.	6–10
Lophospermum scandens. Pink. June to November.	Climber.
Martynia fragrans. Mauve. July to October.	24
Mesembryanthemum tricolor. Crimson and white. July to September.	3
Mina lobata. Scarlet, cream. July to October.	Climber
Nemesia Suttoni. Scarlet, blue, orange. June to October.	6–9
Nicotiana affinis. Crimson, pink, white. May to October.	18–30
Nycterinia selaginoides. Pale blue, orange. June to September.	12
Pentstemon. Various. June to November.	12–24
Perilla nankinensis. Bronze foliage. June to October.	12–20
Petunia. Pink, purple, white. May to October.	12–24
Phlox Drummondii. Carmine, apricot, etc. June to September.	6–12
Portulaca. Scarlet, white, yellow. June to September.	6
Primula obconica. Lilac, white, crimson. October onwards.	10
Primula sinensis. Pink, white, carmine. November onwards.	10
Pyrethrum aureum (Golden Feather). Foliage various, golden. Flowers cream-white. June to December.	5–9

Rhodanthe. Pink, white, crimson. [Ins.] Everlasting. July. 9–12
Ricinus Gibsonii. Bronze foliage. July to November. 24
Salpiglossis. Various. June to October. 15
Salvia Bruantii. Scarlet. August onwards. 15
Schizanthus. Various. July to December. 12–24
Streptocarpus. Violet, rose, white. July to December. 12–15
Torenia. Violet-blue and white. August onwards. 12
Trachelium caeruleum. Pale blue. July to September. 18
Verbena. Various. July to November. 6
Zinnia. Scarlet, apricot, pink. June to October. 15–30

I. L. R.

[Some of the above are half-hardy perennials, or belong to other sections, but they are most conveniently grown by treating them as half-hardy annuals in the manner described in our article on *ANNUALS FOR ALL PURPOSES*.—EDITOR.]

ANNUALS, HARDY.—See *ANNUALS FOR ALL PURPOSES* and *ANNUALS: GENERAL CULTURE OF.*

ANOMATHECA.—Now included in the genus *LAPEYROUSIA.*

ANSELLIA.—See *ORCHIDS.*

ANTENNARIA (CAT'S-EAR. Nat. Ord. Compositæ).—These are low-growing silvery-foliaged plants, forming carpet-like tufts, and useful in the rock garden. They are propagated by dividing the roots in autumn or spring.

Rock Garden Species.—Only one need be described here :—

Antennaria dioica (ALPINE EVERLASTING [1]).—Leaves in small rosettes, hoary. Flowers pink in heads. Site sunny ledges. Soil deep, gritty. Flowering Period, June to July. Height, 3 ins. The variety *tomentosa* (Syn. *A. candida*) has larger silvery leaves. It is a quick grower and very dwarf.

[1] MOUNTAIN CUDWEED is the Kew name for this.—EDITOR.

ANTHEMIS (CHAMOMILE. Nat. Ord. Compositæ).—The common Chamomile (*Anthemis nobilis*) is a well-known medicinal plant, and as such is dealt with in our article on *MEDICINAL HERBS.* Some few are annuals, some are evergreens, but the hardy herbaceous perennials are the most grown for garden purposes.

Culture.—This is a matter of considerable ease. Ordinary common soil suits the plants admirably, and experience has shown that they are not particular as to the position. They are easily increased by division of the roots in the autumn or spring and by seeds also in the spring. Planting may be done any time during the winter months up to early April.

Perennial Border Species.—A good many so-called species of hardy plant specialists are excluded, since they are synonymous with species of other genera. The following are recommended :—

Anthemis fruticulosa.—This is a white sort which is in bloom in late July and August. It rarely exceeds a height of 24 ins.

A. tinctoria.—This is the sort most usually grown in gardens. The range of colour includes various shades of yellow, also white. It blooms from June to August, and the height varies from 12 to 24 ins. There are several varieties, such as *Kelwayi* and *Mrs Brooks.*

Rock Garden Species.—There are only three or four species suitable for the rock garden. These are dwarf and will thrive in well-drained sandy soil. Propagate by dividing the roots in spring, or by seeds sown in heat in March.

Anthemis Aizoon.—See *Achillea ageratifolia.*

A. biebersteiniana.—Leaves in tufts, silvery. Flowers bright golden-yellow. Site sunny. Soil sandy

loam. Flowering Period, June to July. Height, 1 ft.

A. cupaniana.—A trailing sort with silvery foliage. Flowers white. Site sunny. Soil sandy. Flowering Period, June to September. Height, 1 ft.

A. montana.—Leaves in rosettes on sub-shrubby stems, much divided and silvery. Flowers yellow on long stalks. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 1 ft.

A. styriaca.—Leaves silvery in tufts. Flowers white. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 4 ins.

See also under CHAMOMILE in *MEDICINAL HERBS.*

ANTHERICUM.—The same as ANTHURICUM. See *ST. BERNARD'S LILY.*

ANTHOLYZA. — See *PERENNIALS, HALF-HARDY: LIST OF.*

ANTHOMYIA.—See RADISH FLY in *INSECT PESTS.*

ANTHONOMUS. — See APPLE BLOSSOM WEEVIL in *INSECT PESTS.*

ANTHOXANTHUM (Nat. Ord. Gramineæ).—This is a small genus of hardy grasses of no garden value whatever, but desirable for pasture, etc.

ANTHRISCUS (BEAKED PARSLEY. Nat. Ord. Umbelliferæ).—This is an unimportant coarse-growing genus of biennials or perennials sometimes offered as desirable plants to the unwary amateur by dishonest plant salesmen. The best known species is *A. cerefolium*, the CHERVIL of our salad bowls, the culture of which is described in our article on *SALAD PLANTS.* Other species are *A. sylvestris*, the ROUGH CHERVIL, and *A. vulgaris*, the common BUR CHERVIL. None have any beauty for garden decoration.

ANTHURICUM.—See *ST. BERNARD'S LILY.*

ANTHYLLIS (KIDNEY VETCH. Nat. Ord. Leguminosæ).—This is not a genus of much consequence to gardeners. The best known species are *A. montana* (Syn. *A. jacquiniana*) and *A. Vulneraria*, also known as LADIES' FINGERS. Both are hardy herbaceous perennials best propagated by root division in the spring, and of very easy culture if a light soil is provided; both bear their flowers in July, and both average 12 ins. in height. The first bears purple flowers and the second yellow, though various coloured varieties of each are sometimes listed.

ANTICLEA. — Now included in the genus *ZYGADENUS.*

ANTIGRAMME. — Now included in the genus SCOLOPENDRIUM, for which see *FERNS AND FERN GARDENING.*

ANTIPHYLLA.—Now included in the genus *SAXIFRAGA.*

ANTIRRHINUM (SNAPDRAGON. Nat. Ord. Scrophulariaceæ) is a hardy herbaceous perennial of height varying from 9–30 ins. Its flowers are in many beautiful colours. The plant thrives in ordinary well-drained garden soil, and is propagated by seeds and cuttings.

Culture.—Sow seed from June to August in pans or in the open border. Cuttings may be taken in autumn, and will root readily if kept shaded in a frame or under a hand-light. Side-shoots, taken off with a heel, and having about five pairs of leaves, are suitable. By spring they will be well rooted, and should then be planted out where they are to bloom.

USES.—Antirrhinums are very useful for bedding and for covering dry banks and walls in sunny aspects. Tall varieties make handsome clumps in the herbaceous borders, the dwarf and medium ones lending themselves more to colour schemes in

beds. They flower throughout the summer.

Varieties.[1]—These are very numerous. The following are splendid :—

Tall.—Admiration, Amber Queen, Cottage Maid, Fireflame, Mont Blanc, and Nelrose.

Dwarf.—Coccinea, Prima Donna, Sunset, White Prince, and Yellow Queen.—J. L. G.

ANTIRRHINUM : Rock Garden Species.—Only two species of this genus are typical rock garden subjects. These thrive in rock crevices in full sun, and are easily raised from seeds sown in gentle heat in March.

Antirrhinum Asarina (ITALIAN SNAPDRAGON).—Trailing stems and woolly leaves. Flowers white with yellow tip. Site sunny, sheltered. Soil gritty loam. Flowering Period, May to September. Height, 3 ins.

A. glutinosum.—Sub-shrubby trailing stems, forming a bushy plant. Leaves hairy. Flowers yellowish-white, large. Site sunny, sheltered. Soil gritty loam. Flowering Period, May to September. Height, 6 ins.

ANTS.—See *INSECT PESTS.*

APARGIA.—Now included in the genus LEONTODON.

APHACA.—Now included in the genus *LATHYRUS.*

APHANES.—Now included in the genus *ALCHEMILLA.*

APHELENCHUS.—See under EEL-WORMS in *INSECT PESTS.*

APHIDES.—See APPLE AND ROSE APHIDES in *INSECT PESTS.*

APHIDIDÆ.—See ROSE APHIDES or GREEN AND RED FLY in *INSECT PESTS.*

[1] Species are not given much attention for bedding and border work. *A. majus*, the COMMON SNAPDRAGON ; *A. nuttallianum*, *A. Orontium*, the CORNFIELD SNAPDRAGON ; *A. speciosum* and *A. tortuosum* are sometimes grown. Most of the species are now included in other genera.—EDITOR.

APHIS.—See APPLE, BEAN, PLUM, and ROSE APHIS in *INSECT PESTS.*

APHIS BRUSH.—See *GARDEN TOOLS.*

APIUM (Nat. Ord. Umbelliferæ). This is a small genus of biennial plants which are not quite hardy. Three distinct species find a place in the *Kew Hand-list of Herbaceous Plants*, but only one of these is grown to any large extent, namely, *A. graveolens*, and its variety *rapaceum*, better known as CELERY and CELERIAC respectively. On each of these we devote a separate article, to which we refer our readers for details of culture.

APLOPAPPUS (Nat. Ord. Compositæ).—This is a genus of hardy annuals or biennials for the borders, of very easy culture though but seldom grown and of little value. The best known species is *A. ciliatus*, a yellow September blooming plant about 2 ft. in height. For descriptions of other species larger works must be consulted.

APLOTAXIS.—Now included in the genus *SAUSSUREA.*

APONOGETON (CAPE POND FLOWER. Nat. Ord. Naiadaceæ).—This is a useful genus of greenhouse, hardy, and stove aquatics. The first and the last class are excluded as they are beyond our present scope. The best of the hardy section are described under CAPE POND FLOWER in our article on *WATER GARDEN : PLANTS FOR THE.*

APOSERIS.—Now included in the genus *HYOSERIS.*

APPLE (*Pyrus.* Nat. Ord. Rosaceæ).

Culture of.—A few hints may be useful under this head for the guidance of the enthusiast.

The Best Form of Tree for gardens is the Bush to be trained basin-shaped, or the Pyramid. In the Bush trees the central stem is not

allowed to extend. Other forms of trees are dealt with in the General Considerations on Hardy Fruit Culture.

Newly planted trees will not need any manure for three years unless the growth is feeble; it being important to get trees with some well-ripened wood at the start.

When the trees begin to fruit, the clusters should be thinned to one or two fruits only, and if a tree bears freely, a mulch of rotten dung on the surface in June, to be watered upon in dry weather, will ensure the crop swelling to perfection. If no dung is available sprinkle 4 oz. of a first-class fertiliser to the square yard, hoeing it in, and watering upon it.

It is advisable to change the manure applied to Apples each year, in this rotation—Horse or Cow Dung, Lime, Basic Slag, or Wood Ashes, and Sulphate of Ammonia (2 oz. to square yard).

Manure should, of course, be applied only when the growth is feeble, and not necessarily every year, or the tree will grow wood instead of fruit. Attention to Aphis and Caterpillars must be given before the trouble develops, also to diseases. For information on these points readers should turn up our articles on *Apple Diseases* and *Insect Pests*.

SELECTION OF VARIETIES.

In the selections which follow, the varieties of apples are placed under the months in which they commence to be fit for use. Many keep in condition for a much longer period, when stored in a properly constructed Fruit House, as described in our article *Fruit Rooms and Fruit Houses*. For example, *Allington Pippin* is classed under November, but it keeps well till April; and *Cox's Orange Pippin* is of the same behaviour. Planters with limited space should choose one or more varieties from each month, and thus prolong the season. Unless a proper store-house is provided, amateurs will do well not to plant varieties named under the heading "February to May."

DESSERT APPLES (EARLIEST).

Mid-July and August. — These should be eaten direct from the tree, as when stored they become mealy, losing crispness and flavour.

Irish Peach (Crofton).—Small, flat, dull red, with white specks. Soft richly flavoured flesh. Growth spreading and moderate. Bears on tips of shoots. Must be well pruned in when young, or the bush will get too spread out. Regular bearer.

Langley Pippin.—New and promising. Resembles *Mr Gladstone* but is larger, and the growth is more vigorous. Very tender flesh of pleasant flavour.

Mr Gladstone. — Medium size, yellow with crimson blotches and streaks. Flesh soft and pleasant in flavour; growth moderate and compact. Good bearer.

Red Joanetting.—Medium, conical, dull red. Flesh crisp and pleasant. Growth upright and compact. Moderate cropper.

September:—*Devonshire Quarrenden.*—Large, flat, deep crimson. Flesh crisp, flavour rich and sweet; growth compact and upright. Rather uncertain bearer, but worthy of growth on score of quality.

James Grieve.—Large if thinned. Conical. Greenish-yellow, with faint red at times. Flavour briskly acid and pleasant. A Scotch seedling from *Cox's Orange*: valuable for its constant cropping. Grand for small gardens.

Lady Sudeley.—Large—the finest in its season. Flat, angular, richly

coloured on sunny side with russet. Strongly perfumed and of rich spicy flavour when fresh from the tree. Growth upright and free. Regular cropper. When orchard-house grown the fruits are bright scarlet.

St Everard.—Large, crimson and yellow. A seedling from *Cox's Orange* and having a smack of its flavour. Growth upright, free, and stout. Good bearer.

Worcester Pearmain. — Medium, conical, bright crimson, with some russet. Flavour crisp and pleasant when left on tree long enough to mature its growth. Habit upright. Regular bearer.

October :—*American Mother.* — Medium, conical, dull red and yellow, often russety. The richest flavoured October apple, bearing every other year. Growth upright and compact. A first-class sort.

Golden Winter Pearmain is a better variety than *King of the Pippins*, and often grown and sold for it.

King of the Pippins.—Medium size, golden, with red dull flush. Soft flesh, sweet pleasant flavour. Growth upright, very compact. Regular bearer.

Maidstone Favourite.—Large, flat, handsome pale yellow, with bright crimson flush. Flavour rich, and flesh crisp. Growth compact. A very promising novelty.

DESSERT APPLES (LATER).

November :—*Allington Pippin.*—Medium size, large when from young trees. Yellow with pretty red flush and stripes. Compact, free growth. Capital bearer. Succeeds well in the North, and is one of the most reliable, keeping till March.

Cox's Orange Pippin.—Medium size, regularly shaped. The best all-round dessert apple. Fails in heavy soils and is worth a wall in the North. Regular bearer, and compact grower. It may be kept in condition till March.

The Houblon.—Medium size. A highly coloured seedling from *Cox's Orange Pippin.* Tree of sturdy growth, bearing well. Fruit of delicious flavour—so far the best of all the Cox's family seedlings.

December :—*Adams' Pearmain.*—Medium size, and of long conical shape, rich deep red, with specks and russet. Delicious flavour. Regular moderate bearer.

Egremont Russet.—Medium size, though rather flat. Rich flavour. Regular bearer.

King of Tomkins Co.—Large, and evenly shaped—rich crimson fruit of extra fine flavour. One of the few American apples that succeed in Britain. Growth free and sturdy. Moderate bearer. A splendid sort.

Roundway Magnum Bonum.—Very large and rough in appearance, colour green, with russet. The writer considers this by far the richest dessert apple. Its size does not suggest dessert use, but once tasted it is sure to find favour. It succeeds as a standard and bears moderately, though of vigorous growth. Cooked in any form it needs no sugar.

February to May :—*Duke of Devonshire.* — Small pale green, russety, keeps without shrivelling. Rich flavour. Regular bearer.

King's Acre.—Large, green and russety, with bronzy colour, and of rich flavour.

COOKING APPLES (EARLIEST).

Mid-July and August.—These sorts can be cooked direct from the tree, or they may be stored for a few days.

Early Victoria (Syn. *Emneth Early*).—Large, bluntly conical. Pale green. Cooks well. Growth free and upright. Good bearer.

Early White Transparent—Medium size, and conical. Pale primrose

colour. Brisk acid flavour, and worthy of dessert use. Upright habit and free bearer. Quite first rate.

Grenadier.—Very large, flat, pale green. Cooks well and keeps for two months. Growth free. Good bearer.

September :—*Ecklinville Seedling.* —Very large, and of roundish shape. Pale green and speckled. Flesh soft, and fruit cooks without falling. Growth free. Moderate bearer, but often fully laden.

Emperor Alexander.—Very large ; flat. Crimson on sunny side, greenish-yellow on shaded parts. Flesh soft and pleasant—fit for dessert. A noted variety for exhibition. Growth spreading. Free bearer.

Golden Spire.—Medium ; conical. Rich yellow. Keeps for two months. Growth compact. A very free bearer.

Stirling Castle.—Large, round and even. The perfection of a cooking fruit, since there are no waste angles. Flesh soft ; cooks without falling. Growth moderate. It crops so profusely that growth is often checked. Thus in a young state it must be well pruned to secure a tree before the crop checks growth.

COOKING APPLES (LATER).

October :—*Norfolk Beauty.*—Large round, pale yellow. Cooks without falling. Growth spreading. Good bearer, and very desirable.

Rev. W. Wilks.—Very large, pale yellow. Compact growth. Enormous bearer. A splendid variety.

Warner's King.—Very large, flat, pale green. Cooks well. Growth free, and spreading. Apt to canker in heavy soil ; but one of the best.

November :— *Bismarck.* — Large, heavy, flattish, with crimson cheek. Very fine bearer. Compact growth. Cooks well.

Golden Noble.—Medium, good shape. Cooks finely. Bears on spurs wide apart. We consider *Edward VII* (see next month) better.

Royal Jubilee. — Large, pale green, conical. Remarkable for flowering and leafing very late, escaping frosts, and thus missing the ravages of the Codlin Caterpillar. Free bearer. Growth sturdy.

The Queen.—Large, flat, handsome yellow, flushed crimson. Cooks well, and is worthy of dessert use. Growth free, and spreading. Moderate bearer.

December :— *Beauty of Kent.* — Large, conical fruit, of rich yellow colour, with pale crimson flush. Cooks well, and is worthy of dessert use. Free grower. Good bearer.

Edward VII.—See *Golden Noble* above, which it closely resembles but is a better bearer.

Lord Derby.—Large, conical, pale green. Regular bearer. Growth stout and upright.

January : — *Encore.* — Best described as a large *Lane's Prince Albert.* One of the finest recent novelties.

Hamblings. — Large, regularly conical, pale green, heavy. Cooks well. Succeeds in the North. Good bearer when established.

Lane's Prince Albert. — Large, yellow, often flushed red on sunny side. Compact grower, bearing profusely. Indispensable to any garden.

February to May : — *Bramley's Seedling.*—Large, and flat, with eye very deep. Green, with bronzy red flush. Cooks well and keeps splendidly. Very free spreading growth. Good bearer when established.

Newton Wonder.—Large, often highly coloured. A good keeper and cooker, quite worthy of dessert use. Regular bearer, with spreading growth. Superior to *Bramley's Seedling.*

Ontario. — Large and very firm.

Keeps soundly till June. A valuable addition to any orchard. Compact in growth, and bears freely.

Varieties Omitted.—The following are notable varieties and should be included in selections of fifty sorts. They are strongly recommended to those who may already have the thirty varieties described.

For Dessert.—*Chas. Ross* (October and November); *Ellison's Orange* (December); *Lord Hindlip* (late); *St Edmunds* (October); and *Wealthy* (October to November).

For Cooking.—*Annie Elizabeth* (keeps up to May); *Blenheim Orange* (November to May); *Lord Grosvenor* (very early); and *Wellington* (late).

Blenheim Orange is rather too strong in growth for gardens, but bears fairly well on the Paradise Stock. *Wellington* is apt to canker in cold soils. *Lord Hindlip* and *Heusgen's Golden Reinette* are fine very late desserts. Every gardener should also have a *John Downie Crab*; it is beautiful in flower; bearing profusely; and giving a wealth of striking scarlet fruits, which are most useful for jam or jelly.

The reason why such varieties as *Ribston Pippin* are omitted is because they are specially liable to canker. If *Ribston Pippin* must be planted, procure trees on the Paradise Stock, and in the North plant only on walls. In conclusion it will be well to point out that *Golden Spire* and *Irish Peach* should be grown in all Northern and Scottish gardens as they are most suitable for cool exposed situations.—G. B.

New Varieties.

The following are undoubtedly the best:—

Arthur Sheed.—A culinary and dessert variety with medium to large russeted fruits, having a golden and red colouring. It is a heavy and constant cropper, in season from October to March.

Harry Pring.—A culinary variety with large, round, pale green fruits changing to yellow. It is a juicy variety of brisk flavour, and a late keeper, remaining good till May or June.

James Lawson.—A culinary and dessert variety of medium size, with green but red-cheeked fruits. It is a constant bearer and a good keeper, and in season from October to January.

Laxton's Superb.—A dessert variety of medium size, suggesting a *Cox's Orange Pippin* in shape, colouring, and flavour, but coming into season in March.

Monarch.—A culinary variety, with large, round yellow fruits, which are beautifully marked with crimson-scarlet. It is a juicy variety of brisk flavour, and a heavy cropper, in season from October to April.

Parsons' Madresfield Court.—A dessert variety of medium size and conical shape, with attractively coloured, aromatic fruit of *Ribston Pippin* flavour, which is in season from November to February.

Queen Mary.—A dessert fruit of medium size, and golden with crimson colour. It is of good flavour, and an excellent cropper, coming into use in October.

St Cecilia.—A dessert fruit of medium size, green in colour, but prettily marked with crimson. It is of fine flavour (resembling *Cox's Orange Pippin* in this respect), a good bearer, and a very late keeper.

Welford Beauty.—A dessert and culinary variety of medium to large size, with a yellow skin striped with crimson, and of a very handsome shape. It is in season from September to October.

William Peters.—A dessert variety round in shape, of medium size, and with a streaked or crimson

mottled skin. It is of excellent flavour, and is in season from September to January.—W. J. C.

APPLE CANKER. — See *APPLE DISEASES*.

APPLE DISEASES.

[The following notes on Apple Diseases will be of interest to fruit growers. Apple Scab and Brown Rot are also common to pear trees. The remedies are the same as for apples.—EDITOR.]

Apple Canker (*Nectria ditissima*). —This destructive disease is one of the worst enemies to profitable apple-growing in the British Isles. It is favoured by heavy ill-drained soils. The large rugged cankers start as small depressed areas about a dead twig or wound, becoming marked in their later stages with several more or less concentric rings in the bark. These cankers sometimes completely encircle and kill large branches.

Nectria ditissima being a wound parasite cannot attack uninjured bark, but small injuries open the way to its entrance, and it frequently follows the punctures and cracks produced by the woolly aphis.

REMEDIES.—Spraying is useless against this disease and recourse must be had to the knife. Trees that are cankered and no longer bearing well should be cut down and top grafted with an immune variety such as *Bramley's Seedling* or *Newton Wonder*. Trees that are still vigorous and bearing well, though much cankered, may remain. Boughs and shoots affected with canker should be pruned away and the cut surfaces protected by a coating of painters' knotting, tar, white paint, or even clay. Good drainage is helpful in keeping off canker.

Apple Mildew (*Podosphaera leucotricha*).—This widespread malady attacks the leaves, twigs, and flower buds, causing them to curl up and shrivel and covering them with a white mealy coating of spores. Resting spores are scarce, but the fungus winters in the dormant buds, which on opening become centres of new infection in the spring.

REMEDIES.—The disease must be controlled by pruning. Cut away all infected shoots in autumn and go over the trees again thoroughly at flowering time, removing all buds showing traces of mildew. If in spite of this mildew develops, spraying with lime sulphur (1 part in 30 parts water) will help to check it.

Apple Scab (*Venturia inaequalis* and *V. pirini*).—Scab is an exceedingly common and general disease attacking apples and pears, the black specks or blotches, or large unsightly cracks depreciating the mature fruit, while the fruit attacked early in the season is deformed and often falls from the tree. Scabbed apples do not keep well and are liable to rot. The disease appears first as olive-coloured velvety patches on the leaves, from which it spreads to the fruit. The fungus winters on the young wood just below the bark, producing blister-like swellings from which are liberated in the spring myriads of spores.

REMEDIES.—1. All blistered wood should be carefully pruned away in the winter. 2. The disease can be controlled by two sprayings with Bordeaux Mixture (see *SPRAYING MIXTURES*), or, in the case of more delicate varieties, with lime sulphur

(1 part lime sulphur to 30 parts water), (*a*) just before flowering, (*b*) immediately after flowering, and in bad cases a third spraying three weeks later will be found necessary.[1]

Bitter Pit.—This disease is characterised by a pitting of the apple on the outside and spots of brown, dead tissue in the flesh. The cause of the disease is still uncertain, though it is believed to be due to a disturbance of water supply.

REMEDY.—No cure is known.

Blossom Wilt (*Monilia cinerea*). —*Lord Derby, Cox's Orange Pippin,* and *James Grieve* specially suffer. The disease attacks the flowers, and a fortnight later the dead withered truss denotes its presence. The fungus travels down the spur and causes a canker in the branch, which it may encircle and kill. Grey pustules of the disease develop later on the spurs, and the spores from these infect the opening blossoms next spring.

REMEDIES.—The knife must be used. Cut off all affected spurs in summer whilst the dead leaves indicate the disease. When cutting care must be taken to cut back to sound wood. Spraying has so far proved useless.

Brown Rot (*Monilia fructigena*).—This begins as a brown spot in the flesh of the apple, often starting through a wound, or where the apple is in contact with a mummied apple of last year. The disease spreads rapidly through the fruit, rings of grey-brown pustules appear, consisting of myriads of spores. A similar disease attacks plums.

REMEDIES.—Diseased fruit and diseased wood should be collected and burned. It is most important also to collect all mummied fruits from the trees in winter, as it is from these that the disease largely starts in the sprng.

Water-Core of Apples is recognised by a peculiar glassiness or transparence about the core and sometimes extending to the surface or showing as transparent blotches. Water-core is caused by the tissues being over-charged with water due to atmospheric changes, or soil conditions.

REMEDIES.—Affected apples may partially recover if stored under conditions not too damp and cold.

A. D. C.

APPLE MILDEW.—See *APPLE DISEASES.*

APPLE MINT (*Mentha rotundifolia*).—See *MENTHA.*

APPLE ROSE (*Rosa pomifera*).—See *ROSE SPECIES.*

APPLE SAWFLY.—See *INSECT PESTS.*

APPLE SCAB.—See *APPLE DISEASES.*

APPLE SUCKER.—See *INSECT PESTS.*

APPLE WATER-CORE.—See under WATER-CORE in *APPLE DISEASES.*

APPLES: Culture of.—See *APPLE.*

APPLIANCES, GARDEN.—See *GARDEN APPLIANCES.*

APPLYING ARTIFICIALS.—See *WINTER GARDEN, THE;* also *POTASH AND POTASSIUM COMPOUNDS,* and *SODA AND SODIUM COMPOUNDS.*

APPLYING CHALK.—See *SOIL IMPROVEMENT.*

APRICOT (*Prunus.* Nat. Ord. Rosaceæ).—**Culture of.**—This fruit being a native of hot Eastern countries requires a little care in our British climate. It is apt to gum and die back on walls, and should be grown there only on the spur system. Any pruning needed should be done while the trees are in growth, otherwise the wood will gum and the sap be impeded by the gum-

[1] *Cox's Orange Pippin* should never be sprayed with Bordeaux Mixture, but with weak lime sulphur (1 part to 60 parts water).

ming parts, in which case the growth above this dies out. The fact is that all needful growth is completed by August. Then the rains of September start the tree again, and the sappy growth gets cut by the frosts. To obviate this, cover the borders in September to throw off the rains, and remove covering in January. The trees may begin to flower at the end of February, and this bloom must be protected or much fruit will be lost. Thin freely where required, and when gathering the fruit it will be noticed that they are often found to be ripe on one side and hard on the non-exposed side. In that case lay them in the greenhouse, hard side to the sun, and they will then soon become fit for eating—perfect sweetmeats.

Selection of Sorts.—*Grosse Pêche.* — The largest mid-season Apricot.

Kaisha.—Very small, deliciously sweet.

Large Early (Luizet).—Free bearer.

Moorpark.—The best all round kind.

Shipley or Blenheim.—Large and good.

Apricots should be grown as dwarf-trained on east or west walls; or on buildings in paved yards. On house walls, etc., grow them as standards.—G. B.

See also under *Prunus Armeniaca* in *Trees.*

APRICOT PLUM (*Prunus Simonii*).—See *Trees.*

AQUA FORTIS.—A popular name for Nitric Acid, for which see *Acids: Their Uses in Horticulture.*

AQUILEGIA (Columbine. Nat. Ord. Ranunculaceæ).—A hardy herbaceous perennial. Height, 1–3 ft. It succeeds in ordinary well-drained garden soil, and is propagated by seed and division of roots.

Culture.—Sow seed in March for flowering the following spring. Division of roots during the dormant season, autumn for preference, is another easy mode of propagation.

Beds of Aquilegias or bold clumps in the mixed borders make pleasing and dainty colour schemes for the early summer garden, blooming as they do in June and July.

Varieties.—The best sorts are hybrids of species such as *californica hybrida* and *caerulea hybrida*, and the long spurred hybrids from selected seed stocks such as Mrs Elliot, Dobbie's, Barr's, Sutton's, etc.—J. L. G.

AQUILEGIA: Rock Garden Species.

Five are suitable for the rock garden. These are dwarf in habit and mostly biennial. They thrive in deep loamy soil in half-shady positions, and are propagated by means of seeds sown in spring.

Aquilegia alpina.—Divided leaves in tufts. Flowers deep violet-blue, with long spurs. Site half-shade. Soil deep loam. Flowering Period, May to June. Height, 1 ft.

A. caerulea (Rocky Mountain Columbine).—Flowers pale blue and white, 3 ins. across with long spurs. Site half-shade. Soil deep loam. Flowering Period, May to July. Height, 1 ft.

A. canadensis.—Leaves finely divided in tufts. Flowers cinnabar-red and yellow. Flowering Period, April to June. Height, 1 ft.

A. glandulosa.—Flowers dark blue with white edges. Spurs short. Flowering Period, May to June. Height, 1 ft. *A. Stuartii* is a dwarf variety of this.

A. pyrenaica.—Very dwarf in habit. Flowers bluish-lilac, large. Flowering Period, April to June Height, 9 ins.

ARA KASI. (*Quercus glauca*).—See *Trees.*

ARAB'S DISS (*Festuca montana altissima*).—See *Festuca.*

ARABIS (Rock Cress. Nat. Ord. Cruciferæ).—This genus of rock garden plants, which have mostly small flowers, is useful as a carpeting subject for covering rocky ledges, etc. It is propagated by dividing the roots in autumn or spring, and may also be raised from seeds sown in gentle heat in March.

What to Grow.—Below we describe the best :—

Arabis albida (Wall Cress).—A spreading dwarf plant with hoary foliage. Flowers white, large. Site sunny. Soil sandy loam. Flowering Period, April to June. Height, 6 ins.

A. albida fl. pl. (Snowdrift).—A variety with attractive double white flowers.

A. androsacea.—A tufted alpine species with silvery leaves. Flowers white. Site sunny. Soil gritty. Flowering Period, June. Height, 3 ins.

A. Billardieri rosea.—Similar to *A. albida* in habit. Flowers pink. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 6 ins.

A. procurrens.—A free growing species with shining green leaves. Flowers white. Site sunny. Soil sandy. Flowering Period, May to June. Height, 6 ins. (There is a variety of this with variegated leaves.)

New Variety.

Arabis aubrietioides Trevor Seedling.—This has charming deep rose flowers.

ARACHMANTHE.—See *Orchids.*

ARALIA.—For best species see *Shrubs.*

ARAUCARIA.—For the best species see *Trees.*

ARBOR VITAE (*Libocedrus Sp. and Thuya Sp.*).—See *Trees.*

ARBOURS AND ARCHES.

The arbour in an old-world garden was, as its name suggests, a seat in a recess in a hedge or under a tree. Very delightful were those shady nooks roofed in with foliage, and their forms adapted to the spot chosen for the purpose. In many a modern garden, reproducing the gardens of other days, such arbours have been formed, and rustic seats provided under the greenery.

The term arbour has been given a wider meaning by modern folk, and is used synonymously with summer-house and more formal shelters, such as covered-in retreats of wood relieved by split rustic work on the plain surface. An arbour can also be made of open trellis-work and rustic wood, coloured and varnished to contrast with the greenery, which should be near by. The roof of such an arbour should be covered with some waterproof material, or, better still, thatched and made decorative with overhanging eaves. The arbour in a close-cut hedge can be half-round with a dome-shaped top, or merely an oblong structure with open front, the more elaborate summer-houses being closed in, with the exception of the doorway, and enriched with coloured glass panels. Octagonal or sexagonal shaped arbours are much favoured, and such structures add to the ornamentation of the garden.

The professional builder specialises upon such summer-houses and rustic shelters or arbours, and provides tables, seats, plant boxes, and other pieces of garden furniture, *en suite.* The amateur can, however, build many delightful arbours of varied forms, either of plain timber, open trellis, or rustic wood. Such structures are better self-coloured and varnished ; if necessary to paint them, however, garden green, not clashing with the surrounding foliage and colour schemes, is best ; many arbours are made more pleasing by partly covering them with roses, clematis, or similar climbing plants.

The GARDEN ARCH can be made a thing of beauty and a useful trainer for roses and climbing plants. The common arch of iron wire is much favoured for a cheap trainer, so is the wood trellis arch, which may be made very attractive, and the wood arch, which can also be made a support for plants in pots by the insertion of brackets; such arches, too, may be made decorative by adding suspension baskets.

Artistic gardening is a delightful pursuit, and among the schemes introduced for assisting landscape gardening and effecting variety in the perspective, arbours and arches are recommended. As terminals to paths, or as breaks in a somewhat monotonous fence they are very desirable. They can always be used in conjunction with divisions over gates and at intervals along a fence; they are undoubtedly desirable accessories which can be purchased ready-made or built to any design by an amateur. The materials used and the forms in which such arches are built should always be in accord with other woodwork in the garden, as mentioned in our articles on *GARDEN GATES*, *TRELLIS WORK*, etc.

F. W. B.

ARBOURS AND ARCHES FOR ROSES. See ROSES FOR ARBOURS, ARCHES, AND PERGOLAS in *ROSES FOR ALL PURPOSES*.

ARBUTUS.—For the best species see *SHRUBS*.

ARCHANGEL (*Archangelica officinalis*).—See *ARCHANGELICA*.

ARCHANGELICA (Nat. Ord. Umbelliferæ).—This is a small genus of hardy herbaceous perennials resembling *ANGELICA* (which see), and grown in the same manner. The two best species are *A. hirsuta*, bearing white flowers and growing 1–1½ ft. in height; and *A. officinalis* (Syn. *Angelica Archangelica*), used in confectionery, and popularly known as ARCHANGEL, bearing greenish-white flowers and growing 4–6 ft. in height. Both bloom in July, both are easily raised from seed, both are useful on account of their foliage in the wild garden or for shrub borders, and both are excellent town garden plants.

ARCH-BANE.—See HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

ARCHES.—See *ARBOURS AND ARCHES*.

ARCHES, ROSES FOR.—See ROSES FOR ARBOURS, ARCHES, AND PERGOLAS in *ROSES FOR ALL PURPOSES*.

ARCHONTOPHŒNIX.—For the best species see *PALMS*.

ARCTIA.—See TIGER MOTH in *INSECT PESTS*.

ARCTIC CURLED KALE.—See *BORECOLE, or KALE*.

ARCTIUM (BURDOCK. Nat. Ord. Compositæ).—This is a genus of hardy herbaceous plants of no value whatever for garden purposes. They are troublesome weeds in some districts. One kind of Burdock (*A. Lappa*) is a very useful medicinal plant, and is described under its English name in our article on *MEDICINAL HERBS*.

See also under BURDOCK in *MEDICINAL HERBS*.

ARCTOSTAPHYLOS.—For the best species see *SHRUBS*; see also under BEARBERRY in *MEDICINAL HERBS*.

AREAS OF BEDS AND BORDERS.—See *ARITHMETIC AND GARDENING*.

ARECA.—See under CHRYSALIDOCARPUS and RHOPALOSTYLE in *PALMS*.

AREMONIA.—Now included in the genus *AGRIMONIA*.

ARENARIA (SANDWORT. Nat. Ord. Caryophyllaceæ).—This is a dwarf creeping or tufted plant, and a few of its species are suitable for the rock garden. It is propagated by dividing the roots in autumn or spring, and by seeds sown in gentle heat in March.

Rock Garden Species.—The most useful and desirable are described below :—

Arenaria balearica.—A moss-like plant, clinging to damp rocks, forming a deep green carpet. Flowers white in great profusion. Site half-shady, and shade. Soil rocky. Flowering Period, summer (June to August). Height, 1 in.

A. grandiflora.—A dwarf creeping plant with wiry stems, and narrow silvery-grey leaves. Flowers white. Site sunny. Soil sandy loam. Flowering Period, May to July. Height, 4 ins.

A. montana.—A dwarf creeping plant with wiry stems, and green leaves. Flowers white, large. Site half-shade. Soil sandy loam. Flowering Period, May to July. Height, 4 ins.

A. purpurascens. — A creeping plant, with wiry stems. Flowers reddish-purple. Site half-shade. Soil gritty. Flowering Period, May to July. Height, 3 ins.

A. tetraquetra.—This forms compact tufts of closely packed rosettes in the form of a mound. Flowers white. Site sunny. Soil gritty. Flowering Period, August. Height, 4 ins.

ARETIA.—Now included in the genus *ANDROSACE.*

ARISTELLA.—Now included in the genus *STIPA.*

ARISTOLOCHIA. — For the best species see *CLIMBING AND TRAILING PLANTS.*

ARITHMETIC AND GARDENING.

It often happens in connection with various gardening operations that simple arithmetical calculations have to be made. These calculations sometimes prove a stumbling-block to those whose schooldays are some distance behind them. It is therefore the object of this article to set forth clearly certain simple methods which it is hoped will prove useful. The strictest accuracy is not aimed at, especially as with the rough methods of measuring usually adopted, it would be unobtainable.

Arithmetical Constants.—The following list will be useful :—

(1) A cubic foot of water weighs 1000 oz.
(2) A cubic yard of water weighs $\frac{3}{4}$ ton.
(3) A pint of pure water weighs $1\frac{1}{4}$ lb.
(4) A gallon of water weighs 10 lb.
(5) A gallon occupies 277 cub. ins.
(6) About $6\frac{1}{4}$ gallons occupy 1 cub. ft.

A "table-book" will be useful for reference. The following facts are constantly wanted :—

12 ins.	= 1 ft.
144 sq. ins.	= 1 sq. ft.
1728 cub. ins.	= 1 cub. ft.
$5\frac{1}{2}$ yds.	= 1 pole.
$30\frac{1}{4}$ sq. yds.	= 1 sq. pole.
22 yds.	= 1 chain (the length of a cricket pitch).
10 sq. chains	= 1 acre.
4840 sq. yds.	= 1 acre.
8 pints	= 1 gallon.
8 gallons	= 1 bushel.
2240 lb.	= 1 ton.
Standard brick	= $9 \times 4\frac{1}{2} \times 3$ ins.

Areas of Beds and Borders.—Very often it is necessary to estimate the area of flower-beds of different shapes. The following notes will thus be useful :—

CIRCULAR BEDS : *Example.*—If o is the centre, the area is $3\frac{1}{7} \times$ oa $\times$ oa.

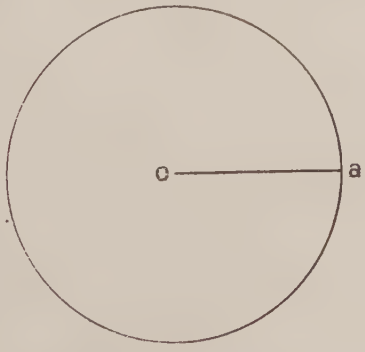

FIG. 1.

Thus if the radius oa is 10 ft., the area is $3\frac{1}{7} \times 10 \times 10$

$$= \frac{22}{7} \times 10 \times 10$$
$$= \frac{2200}{7}$$
$$= 315 \text{ sq. ft. nearly.}$$

ELLIPSE-SHAPED BEDS: *Example.*—The Area $= 3\frac{1}{7} \times oa \times ob$.

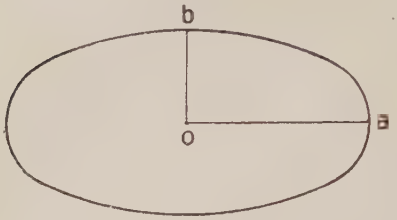

FIG. 2.

Thus if **oa** is 10 ft., and **ob** is 7 ft.,

$$\text{Area} = \frac{22}{7} \times 10 \times 7 = 220 \text{ sq. ft.}$$

HEXAGONAL AND OCTAGONAL BEDS: *Example.*—The area of the hexagon **abcdef** is six times the triangle **oed.**[1]

So if **de** is 10 ft. and **ok** is 8 ft.

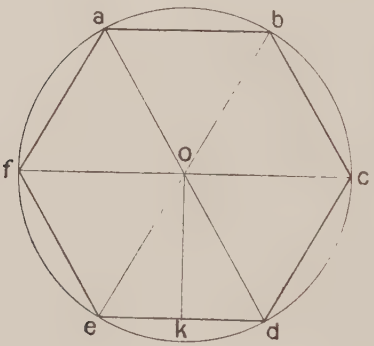

FIG. 3.

Area of hexagon $= 6 \times \frac{1}{2}(10 \times 8)$

" $= 6 \times 40$

" $= 240$ sq. ft.

The area of an octagon would be *eight* times the corresponding triangle.

RECTANGULAR BEDS: *Example.*—If **ab** is 10 ft., and **bc** is 7 ft., the area is $ab \times bc = 10 \times 7 = 70$ sq. ft.

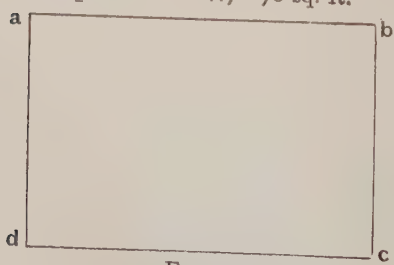

FIG. 4.

[1] For areas of triangles see later.—EDITOR.

TRIANGULAR BEDS: *Example.*—If **bc** is 10 ft., and **ad** 6 ft., the area is $\frac{1}{2}(bc \times ad) = \frac{1}{2}(10 \times 6) = 30$ sq. ft.

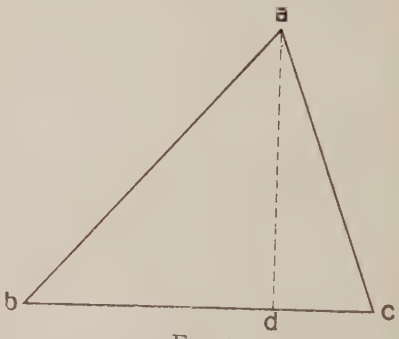

FIG. 5.

Percentages.—Suppose it is required to make up a mixture of 60 lb. of three different fertilisers A, B, and C, and that the mixture is to contain 30 per cent. of A, 25 per cent. of B, and 45 per cent. of C.

A must be $\frac{30}{100}$ of 60 lb.

B must be $\frac{25}{100}$ of 60 lb.

C must be $\frac{45}{100}$ of 60 lb.

So we must take $\frac{3}{10}$ of 60 or 18 lb. of A.

$\frac{1}{4}$ of 60 or 15 lb. of B.

$\frac{9}{20}$ of 60 or 27 lb. of C.

Another kind of percentage problem often arises in seed sowing. Suppose a certain kind of vegetable seed is known only to germinate up to 80 per cent. and 1000 plants are required, how many seeds must be sown?

$$\text{In this 80 per cent.} = \frac{80}{100} = \frac{4}{5}$$

$\therefore \frac{5}{4}$ of 1000 seeds must be sown.

$$= \frac{5}{\cancel{4}} \times \frac{\overset{250}{\cancel{1000}}}{1} = 1250 \text{ seeds.}$$

When the germination is only 50 per cent. and 1000 plants are required, it will, of course, be necessary to sow twice as many seeds as the plants wanted.

Thermometers.—To change from Centigrade to Fahrenheit double the

Centigrade number, take off one-tenth, and add 32.

Example.—Express 25° C. in the Fahrenheit scale.

Double 25	= 50
Take off $\frac{1}{10}$ =	5
	45
Add	32
Result	77

Thus 25° C. = 77° F.

To change from Fahrenheit to Centigrade. Subtract 32, add one-ninth, and take half the result.

Example.—Express 100° F. in the Centigrade scale.

	100
Subtract 32	32
	68
Add $\frac{1}{9}$	7·5
	75·5
Take half	37·7

Thus 100° F. = 37·7° C.

Unit Values.—These are used in calculating the cost of manures or fertilisers per ton. The current price per unit of nitrogen, soluble phosphate, insoluble phosphate, and potash can be obtained from the more technical newspapers dealing with advanced agriculture or with chemistry.

To estimate the cost per ton of a compound fertiliser, multiply the unit value of each of the four constituents above by the percentage present in each case, and the total of the four gives the cost.

Example.—Let the cost of a unit of each of the constituents be as follows: Nitrogen, 12s. 6d.; soluble phosphate, 1s. 6d.; insoluble phosphate, 1s.; and potash, 3s. 6d. Let the percentages of these four constituents be as follows: Nitrogen, 10 per cent.; soluble phosphate, 15 per cent.; insoluble phosphate, 20 per cent.; and potash, 5 per cent.

Then the total cost of the manure of fertiliser per ton is—

$$(12\tfrac{1}{2} \times 10) + (1\tfrac{1}{2} \times 15) + (1 \times 20) + (3\tfrac{1}{2} \times 5) \text{ s.}$$

$$= \left(\frac{25}{2} \times \frac{5}{10}\right) + \left(\frac{3}{2} \times 15\right) + 20 + \left(\frac{7}{2} \times 5\right) \text{ s.}$$

$$= 12\tfrac{5} + 22\tfrac{1}{2} + 20 + 17\tfrac{1}{2} \text{ s.}$$

$$= 185\text{s.} = £\frac{185}{20} = £9\ 5\text{s. per ton.}$$

The method of working is exactly the same where the percentages or unit values are more complex, or in the case of where one or other of the four constituents is absent.

Volumes.—This kind of calculation probably occurs more frequently than any other in gardening.

Capacity of Barrels.—Find the volume of a barrel 4 ft. high, whose average circumference is 8 ft., and radius 15 ins.

Here we use another rule for obtaining the area of a circle.

Area of circle = $\frac{1}{2}$ circumference × radius.

Area of top of a similar cylindrical barrel—

$= \frac{1}{2} \times 8 \times 1\frac{1}{4}$ sq. ft.

$= 5$ sq. ft.

Volume of barrel = $4 \times 5 = 20$ cub. ft. approximately.

When the barrel bulges much, this rule will not be safe.

Capacity of Cylinder.—Find the area of the circular top and multiply by the height.

Example.—Find the volume of a circular hole 4 ft. in diameter and a yard deep.

The area of the circular top

$= 3\frac{1}{7} \times 2 \times 2$ sq. ft.

The volume = $3\frac{1}{7} \times 2 \times 2 \times 3$ cub. ft.

$$= \frac{22}{7} \times 2 \times 2 \times 3 = \frac{264}{7} = 38 \text{ cub. ft. nearly.}$$

Capacity of Tanks or Boxes.—To find this measure the inside length, breadth, and height, and multiply these together.

Example (i.).—Find the volume of a tank whose inside measurements are 3 ft. 6 ins., 2 ft. 8 ins., and 4 ft. 9 ins.

The volume is—

$(3\frac{1}{2} \times 2\frac{2}{3} \times 4\frac{3}{4})$ cub. ft.

$$= \frac{7}{2} \times \frac{8}{3} \times \frac{19}{4} \text{ cub. ft.}$$

$$= \frac{133}{3} = 44\tfrac{1}{3} \text{ cub. ft.}$$

Example (ii.).—How many gallons of water would the above tank hold?

As $6\frac{1}{4}$ gallons go to a cub. ft., the number of gallons is roughly—

$6\frac{1}{4} \times 44$, or 275 gallons.

Example (iii.).—What weight of water would fill the tank?

As a gallon weighs 10 lb., the weight is 2750 lb., or about $1\frac{1}{4}$ tons.

Cubical Contents of Greenhouses.—How many cubic feet of air are contained in a greenhouse whose length is 20 ft., and the end view of which is drawn on the next page?

Find the areas of the triangle abc and the rectangle bcde by the rules already given. Add these together, and multiply by the length—in this case 20 ft.

Thus if abc is 100 sq. ft.
and bcde is 250 sq. ft.,

there are 350×20 or 7000 cub. ft. of air in the greenhouse. The directions furnished with fumigating compounds are usually per 1000 cub. ft., and unless a proper calculation such as the above is made the plants may be severely injured by an overdose of the smoke.

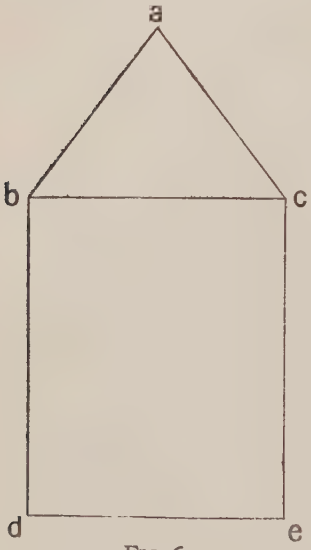

FIG. 6.

GRAVEL FOR PATHS.—What amount of gravel will be required for a layer 3 ins. thick on a path 50 yds. long and $1\frac{1}{2}$ yd. wide?

The volume required will be—

$(150 \times 4\frac{1}{2} \times \frac{1}{4})$ cub. ft.,

$= \frac{\overset{75}{\cancel{150}}}{1} \times \frac{9}{\cancel{2}} \times \frac{1}{4}$ cub. ft.

$= \frac{675}{4} = 169$ cub. ft. nearly.

Taking the volume of a ton of gravel as 20 cub. ft. we shall want $\frac{169}{20}$ or about $8\frac{1}{2}$ tons.

PLANTS REQUIRED FOR DIFFERENT AREAS.—How many plants will be required for a bed 10 ft. × 12 ft., if they are planted 6 ins. apart?

It will evidently be possible to put 23 plants along dc, supposing each plant to be 6 ins., from the edge, and 19 along ad.

Thus the number required is

23×19, or 437 plants.

SOIL FOR BORDERS.—How many tons of soil will be required to fill a border 20 yds. by 10 ft., and 1 ft. deep?

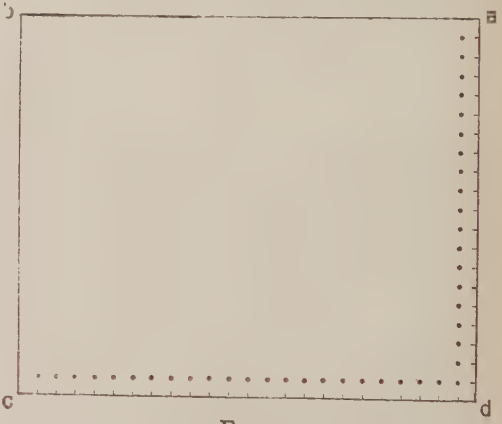

FIG. 7.

The volume of the bed is $60 \times 10 \times 1 = 600$ cub. ft.

Taking the volume of a ton of soil as 24 cub. ft., we shall want $\frac{600}{24}$, or 25 tons.

WALL BUILDING.—How many tons of bricks will be required to build a single ($4\frac{1}{2}$ ins.) wall 5 ft. high, and 50 ft. long?

If abcd represents the bottom layer, and dm represents a brick, we shall want $\frac{50 \times 12}{9} = \frac{50 \times \overset{4}{\cancel{12}}}{\underset{3}{\cancel{9}}} = \frac{200}{3}$ or about 67 bricks for this layer.

FIG. 8.

The number of layers will be $\frac{5 \text{ ft.}}{3 \text{ ins.}} = 20$.

Therefore 67×20 or 1340 bricks will be wanted.

Taking the weight of a brick as 8 lb., the total weight required will be

$$\frac{1340 \times 8}{2240} = \frac{\overset{67}{\cancel{1340}} \times 8}{\underset{28}{\cancel{2240}}} = \frac{67}{14} \text{ tons},$$

or roughly 5 tons, with some allowance for wastage.

Weight of Bushel.—A useful method of finding the weight of a bushel of anything is to weigh a pint of the substance as accurately as possible, and then multiply by 64.

S. B. L. & E. T. E.

ARIZONA CEDAR (*Cupressus Benthami arizonica*).—See *TREES*.

ARMERIA (CUSHION PINK, SEA PINK, and THRIFT. Nat. Ord. Plumbaginaceæ).—This is a genus of evergreen tufted plants, one or two of the dwarfer kinds being excellent rock garden subjects. To propagate divide the roots in the spring.

Armeria alpina.—This is a robust species. Flowers purple. Site sunny. Soil rocky. Flowering Period, July to August. Height, 6 ins.

A. caespitosa.—This is the smallest species, with bluish-grey leaves in compact tufts. Flowers pale lilac in large heads. Site sunny. Soil rocky. Flowering Period, May and June. Height, 2 ins.

A. latifolia (Syn. *A. Cephalotes* and *A. mauritanica*).—This bears broad leaves in loose tufts. Flowers rosy-lilac and other colours in large heads. Site open. Soil deep loam. Flowering Period, May to July. Height, 1 ft.

A. maritima (Syn. *A. vulgaris*).—This is the COMMON THRIFT. Flowers pink, white, crimson, or purplish above grass-like foliage. Site sunny. Soil ordinary. Flowering Period, May and June. Height, 4 ins.

A. mauritanica.—A synonym of *A. latifolia*, which see.

A. plantaginea.—This has plantain-like leaves. Flowers rose-pink and many other colours, in large heads. Site open and sunny. Soil deep loam. Flowering Period, May to July. Height, 1 ft.

A. vulgaris.—A synonym for *A. maritima*, which see.

[There are a number of other species of this genus grown at Kew and in gardens where space is no object. The above selection includes only the cream of the species.—EDITOR.]

ARMORACIA.—Now included in the genus COCHLEARIA.

ARNEBIA (Nat. Ord. Boraginaceæ). Everyone familiar with the beauty of *Macrotomia echioides* (see *MACROTOMIA*), perhaps better known as *Arnebia echioides*, will appreciate the charms of the allied but annual *A. cornuta* and *A. Griffithii*. The first may reach a height of 1½ ft., from an April sowing out of doors, though March sowing in a frame generally gives better results. The flowers are yellow, with a black spot on each petal. *A. Griffithii*, with rich yellow flowers, grows 9 ins. high. Both bloom from June onwards.

See also *MACROTOMIA*.

ARNICA (LAMB'S SKIN. Nat. Ord. Compositæ).—Although there are many species in this genus, only one is usually considered worth growing, and is a rock plant. This (*Arnica montana*) requires well-drained gritty loam in full sun. It is propagated by dividing the roots in the spring or by seeds sown in gentle heat in March which come up freely. The flowers produced on branching stems are orange-yellow and are given in May, June, and July. The height is about 1 ft.

ARONICUM.—Now included in the genus *DORONICUM*.

ARPOPHYLLUM.—See *ORCHIDS*.

ARRANGEMENT OF ORCHARD TREES.—See *ORCHARD: MAKING AND MANAGEMENT OF.*

ARRANGEMENT OF PLANTS.—See *HERBACEOUS BORDERS: MAKING NEW.*

ARRANGEMENT OF SCHOOL GARDEN.—See *SCHOOL GARDENING.*

ARROW-GRASS (*Triglochin.* Nat. Ord. Naiadaceæ).—This is a small genus of hardy grasses succeeding in marshy land. Two forms are usually grown, the SEA ARROW-GRASS (*T. maritimum*) and the MARSH ARROW-GRASS (*T. palustre*). Both average about 12 ins. in height.

ARROW-GRASS, MARSH. — See *ARROW-GRASS.*

ARROW-GRASS, SEA.—See *ARROW-GRASS.*

ARROW-HEAD.—See *WATER GARDEN: PLANTS FOR THE,* and *SAGITTARIA.*

ARROW-WOOD (*Viburnum dentatum*). See *SHRUBS.*

ARSENATE OF LEAD.—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION.*

ARTEMISIA (LAD'S LOVE, OLD MAN, SOUTHERNWOOD, TARRAGON, WORMWOOD, etc. Nat. Ord. Compositæ).—Some species of this genus are described elsewhere in this Dictionary under their English names in the articles on *MEDICINAL HERBS* and *POTHERBS.* They are not largely used in gardens except as herbs, but may be set in the perennial border, rock garden, or wild garden. They succeed in common light rich garden soil in any open position and have pleasingly scented foliage. There are some half-hardy or greenhouse sorts which we need not trouble to notice here.

Perennial Border Species. — A very large number have been described, of which the following is a selection. All may be propagated by root division in the autumn or spring, or by seeds sown in the usual way.

Artemesia argentea. — A useful yellow or white species blooming from June onwards, and about 2 ft. high.

A. austriaca.—A sort with brownish flowers blooming in September, and about 18 ins. high.

A. cana.—A yellow sort blooming in July and August. Average height, 30 ins.

A. lactiflora.—This is probably the most popular sort. Its flowers are white, the foliage is fine, and the plant blooms freely in September and October. Its height is 2–4 ft.

A. pontica.—A yellow September blooming sort averaging a yard in height.

Rock Garden Species. — Three only are valuable for the rock garden, and these may be grown in rock crevices as foliage plants. They are propagated by cuttings in July.

Artemisia Baumgarteni. — This has silvery much divided leaves in tufts on sub-shrubby stems. Flowers yellowish. Site warm, well drained. Soil gritty. Flowering Period, July. Height, 6 ins.

A. lanata.—The leaves of this are softly woolly and silvery, on sub-shrubby prostrate stems. Flowers dull white. Site a warm rock crevice. Soil gritty. Flowering Period, July. Height, 6 ins.

A. vallesiaca.—This has much divided and silvery-white leaves on erect branching stems. Flowers dull white. Site sunny. Soil gritty, well-drained. Flowering Period, June to July. Height, 12 ins.

See *SHRUBS,* and under MUGWORT, SOUTHERNWOOD, and WORMWOOD in *MEDICINAL HERBS.*

ARTHROLOBIUM.—Now included in the genus *ORNITHOPUS.*

ARTICHOKE, CHINESE. — See *CHINESE ARTICHOKE.*

ARTICHOKES (Syn. SUNROOT. Nat. Ord. Compositæ).—Three distinct kinds of these are cultivated in this

country, the Chinese (*Stachys Sieboldi*) — for which see separate article—the Globe (*Cynara Scolymus*), and the Jerusalem (*Helianthus tuberosus*). The first mentioned finds little favour among those owning small gardens, but where there is plenty of room, and variety in vegetables is appreciated, it is usually given a place.

Globe Artichokes (*Cynara Scolymus*) are cultivated for their large edible heads; these are in season throughout the summer and early autumn, and by many regarded as a great delicacy. The plant, which is of handsome appearance, is not really hardy, and, especially where the soil is wet or badly drained, protection should be given at the approach of severe weather.

PROPAGATION is effected by seeds, or offshoots, the former being sown in heat early in March, or later in the open garden. Planting out should be done when sufficiently hardy, or large enough to handle. Give a well-manured soil, allowing from 30 to 36 ins. between the plants, and not less than 5 ft. between the rows. No heads should be allowed to develop the first season. Offshoots may be planted in early spring, giving copious waterings throughout the summer.

Jerusalem Artichokes (*Helianthus tuberosus*) are by far the most popular, and succeed well in almost any district. On heavy ground the tubers although produced in abundance are usually of very irregular shape, this being less apparent when plenty of ashes or road-sand is added before planting. Where the soil is of a sandy nature the shape of these is more even and the table quality is better. Planting may be done any time from January to the end of March. Set the tubers 18 ins. apart, in rows 2 ft. asunder. The crop may be lifted in November, or left in the ground to be dug as required for use.

Two distinct varieties are now in general cultivation, the old purple skinned, and the newer Sutton's White. This latter is far and away the better of the two, and is recommended for all soils.—F. R. C.

See also *CYNARA*.

ARTIFICIAL FENCES.—See *GARDEN FENCES*.

ARTIFICIAL FERTILISERS:

Their Use in the Garden.—The term artificial manure is usually meant to include any manure that is prepared by some manufacturing process (such as is carried out in the case of superphosphate). This distinction is unfortunately not as definite as might be desired; for instance, guano is merely dried dung, and yet is always referred to as an artificial. A further distinction between artificial and natural manures may be borrowed from the realm of chemistry. It is known that chemical infertility of a soil is usually due to deficiency in one or more of the most readily exhausted ingredients of the soil necessary for plant food, namely, Nitrogen (in compound form), Phosphates, or Potash. Artificial manures are usually applied for the purpose of supplying the deficiency of one or two of these ingredients; the needs of a soil deficient in all three substances that make for fertility are best met by an application of a natural manure.

Storage of Artificials.—If any fertiliser is to be used with the greatest success it must be properly stored or it may lose much of its value. Natural manures such as dung may greatly improve by being stored, but this is never true in the case of artificials. They must be carefully stored in a perfectly dry place, preferably with a concrete

floor if a satisfactory texture and chemical composition are to be preserved. Even when stored under the best conditions they may become lumpy and have to be crushed or sieved before application. Manures most liable to spoil when stored are :—Dissolved Bones, Nitrate of Ammonia, Nitre Cake, Nitrate of Lime, Nitrolim (or Calcium Cyanamide), Superphosphate, and the higher grades of guano.

What Not to Mix.—To lessen the work of applying artificials they are often mixed, but there is usually a risk of loss if the components of the mixture react upon one another. Before mixing any artificials the following rules should be learnt :—

Firstly, Acid manures, such as Superphosphate of Lime or Dissolved Bones, should not be mixed with nitrates, since one spoils the other.

Secondly, Lime, or other manures containing lime, such as Basic Slag, should not be mixed with Sulphate of Ammonia or any organic manure that may contain ammonia, for a similar reason.

Thirdly, Superphosphate of Lime should not be mixed with Basic Slag or any other manure containing insoluble phosphates, for if it is the plants will less readily take up the phosphate contained in the former.

Kainit and Nitrate of Soda should not be mixed, as the product will set hard. Any other artificials not mentioned above may be safely mixed.

When to Apply.—The time of application greatly influences the effects of any artificial manure; quick acting manures such as Nitrate of Ammonia, Nitrate of Lime, Nitrate of Potash, Nitrate of Soda, Phosphate of Ammonia, Phosphate of Potash, etc., are best applied to growing crops, and if the land is dressed with them before planting much of their value is lost. Sulphate of Ammonia may be satisfactorily applied at the time of sowing seeds or planting tubers and sets, since it undergoes a process of nitrification in the soil before it is made use of by the plant. Salt, however, should not be applied at sowing time as it is apt to injure tiny seedlings.

Basic Slag is usually applied in the autumn for the succeeding crop, and the same remark applies to Gaslime, which in the fresh state contains substances poisonous to plants. By applying the latter to the land in the autumn, the action of the air renders these substances harmless before the growing season comes on. Kainit also is more suitable for autumn and winter application on heavy or limestone soils, but on light soils (which are most benefited by this fertiliser) should be applied in the early spring. Granulated Nitrolim should also be put on in the winter or early spring to give it time to lose the power, possessed by some samples, of injuring growing crops.

When fertilisers are applied to growing crops, care is necessary in the case of dusty compounds such as ground Nitrolim and Nitrate of Ammonia, which have a scorching action on the foliage and which may in the case of broad-leaved plants easily kill them entirely.

As the usual object for which artificial manures are applied is the benefiting of the immediately succeeding crop, the majority are spring sown. There is no objection, however, to applications at other seasons of the year except in so far as rapid-acting manures are concerned, and these are readily determinable by the fact of their containing readily soluble chemical substances, the amounts of which can be immediately ascertained by reference to the chemical

analysis which the purchaser has always the right to claim from the vendor.

Fertilisers for Various Soils.—Certain artificials are specially suited to certain classes of soils. We give details of the best for the two chief classes of soil below :—

Artificials for Heavy Soils.—Nitrate of Soda is especially suited for clay land which contains a sufficiency of potash, and this the dressing of Nitrate of Soda helps to bring into use.

Basic Slag gives pronounced results on heavy land, while on light land is often without apparent effect.

Wool Waste and other artificials of a bulky nature are particularly valuable for improving the texture of heavy land.

Artificials for Light Soils.—Kainit and other potash manures (such as Carnallite, Muriate of Potash) are particularly valuable on light soils.

Wood Ashes are of more value to

TABLE OF ARTIFICIAL FERTILISERS.

Name of Fertiliser.	Amount to apply Dry (Per 30¼ sq. yards).	Amount to use Wet (Per gallon of water, per 30¼ sq. yards).
Basic Slag.	7½–15 lb.	Not soluble, so not used.
Bone Meal.	4 – 8 lb.	Not soluble, so not used.
Chalk.	30 –90 lb.	Not soluble, so not used.
Chloride or Muriate of Potash.*	2 – 4 lb.	Not used.
Chloride of Soda (Salt).*$_2$	2 lb.	Not used.
Cyanamide.	1 – 2 lb.	Not used.
Dissolved Bones.	4 – 8 lb.	1½ oz. per gal., 40–80 gals.
Guano.	4 lb.	½ peck per 36 gals.
Horn and Hoof Refuse.	20 lb.	Not soluble, so not used.
Kainit.*	4 lb.	Not used.
Lime (Quicklime).	1 – 3 lb.	As much as will dissolve.
Nitrate of Ammonia.	7½– 9 oz.	½ oz. per gal., 15–18 gals.
Nitrate of Potash.*	1 lb.	¾ oz. per gal., 21 gals.
Nitrate of Soda.*$_1$	1 – 2 lb.	¾ oz. per gal., 21–40 gals.
Nitrolim.	2 lb.	Not used.
Phosphate of Ammonia.	Only used in solution.	½–½ oz. per gal., 10–20 gals.
Phosphate of Lime.	See Bone Meal.	Not soluble, so not used.
Phosphate of Potash.	Only used in solution.	½–½ oz. per gal., 10–20 gals.
Phosphate of Soda.	Only used in solution	½–½ oz per gal., 10–20 gals.
Refuse from Carbide.	15 lb.	Not used.
Salt.*$_2$	2 lb.	Not used.
Soot.	Sufficient to colour ground black.	1 peck to 40 gals., 40 gals.
Sulphate of Ammonia.	1½ lb.	1 oz. per gal., 24 gals.
Sulphate of Lime (Gypsum).	12 –15 lb.	Not used.
Sulphate of Potash.*	2 – 4 lb.	½–¾ oz. per gal., 60–80 gals.
Superphosphate.	4 – 6 lb.	1 oz. per gal., 60–70 gals.
Wood Ashes.	15 –20 lb.	Not used.
Wool Waste.*$_3$	10 lb.	Not soluble, so not used.

In the above table the suitability of fertilisers to particular crops is denoted as follows :—

* For Asparagus, Carrots, Cauliflowers, Globe Artichokes, Onions, and Parsnips.

*$_1$ For Spinach and Green Peas improved in cooking qualities.

*$_2$ For Beet and Sugar Beet.

*$_3$ For Hazel Nuts, Damsons, Hops.

light land than heavy land—the latter being less deficient in potash.

Superphosphate is a better artificial than Basic Slag for the addition of phosphate to light land. Bone Meal and Dissolved Bones are also suitable.

What to Avoid.—Applications of artificials that may be expected to give unsatisfactory results are :—

Sulphate of Ammonia applied to a soil deficient in Lime.

Superphosphate of Lime applied to a sour soil, particularly if the crop to be grown is susceptible to an acid condition of soil. (Turnips and Cabbages, for instance, are very liable to become "clubbed" when so treated.)

For gardening practice in the use of artificial fertilisers it is useful to remember that a dressing of 1 oz. per square yard represents a dressing of about 2½ cwt. per acre.

We give on p. 63 a table of Artificial Fertilisers in which brief details are set out as to their mode of application.—P. H. F.

[Further hints on the use of artificials will be found in our articles *Lime Compounds*, *Potash and Potassium Compounds*, *Soda and Sodium Compounds*, etc.—Editor.]

ARTIFICIAL FLAGSTONES.

Flagstones are costly and often very difficult to get, but are so useful for hearths, etc., in greenhouses that they are practically indispensable to gardeners. Where natural stone is not available they can be easily made as follows :—

Have ready a large wooden seed-box of the size the stone is required and line it carefully with a double thickness of newspaper. Fill the box with concrete (see article on *Mortar*), to within an inch of the top, taking care that the corners are not left "hollow," and smooth the surface with a mortar trowel, pressing loose stones into the body of the mixture. Pour off any excess of water which may rise to the surface and put on a layer half an inch thick of Cement for Facing (see article on *Mortar*), smoothing this well out. Allow to set for about a week, then turn the box over and give its bottom a few knocks with a hammer and the flag will drop out. After drying for a day or two longer it is ready for laying.

ARTIFICIAL MANURES FOR VEGETABLES.—See *Vegetables : General Considerations*, and under Food for All Crops in *Feeding Plants*.

ARTIFICIAL STONE. — See Rockwork.

ARTIFICIALS FOR HEAVY AND LIGHT SOILS. — See under Fertilisers for Various Soils, in under *Artificial Fertilisers*.

ARUM LILY. — A name applied to *Richardia africana*. See *Arum Lilies*.

ARUM LILIES (*Richardia*. Nat. Ord. Araceæ).—These are greenhouse perennials with fleshy rootstocks, and either white or yellow flowers. The decorative part of the so-called flower is really a spathe, the true flowers being borne on the central part or spadix.

Culture.—They like a rich soil, hence when potting the mixture of loam and sand should be enriched with good old cow manure and some bone meal. The dry rhizomes are best obtained in August or September, when they should be at once potted in good large pots. Three crowns may be put in an 8- or 9-inch, or one in a 6-inch, pot. Stimulants should be applied whenever the pots have become full of roots. The winter temperature under glass should not fall below 45° F. In summer, that is, when all danger from frost is over, the pots may be plunged in the open air, or the plants turned out into

a border, where they may remain until they are repotted in early September preparatory to their being again housed. During the time the plants are outside, they need copious supplies of water and regular feeding with stimulants, care being taken, if proprietary articles are used, to apply only as directed on the bag or tin.

In the southern parts of the British Isles, the Arum Lily (*Richardia africana*) is sometimes planted in shallow water from 1 to 2 ft. deep round the edges of lakes and pools, and is wonderfully effective when it really flourishes in such positions.

The yellow-flowered species require more heat in the winter than the old white varieties. They must be kept under glass all the year round. These (yellow-flowered) species and varieties may be repotted in February when they are beginning to grow, after their period of almost dryness from October to the end of January, when they are quiescent. Water must be given very sparingly indeed, if at all, during this period. The temperature should be about 60° F. when they are growing.

Species and Varieties :—*Richardia africana* (the old *Calla æthiopica*).—This is the well-known Arum Lily, so much used in floral decorations and wreaths. The spathe is large and white. Care must be taken to fumigate whenever there is any sign of greenfly, or the pure whiteness of the spathe will be sullied. Seminal varieties have of late appeared. Of these *Little Gem* is hardly half the size of the type. *Childsiana, Pearl of Stuttgart,* and *The Godfrey* are useful. The last claims to be extra free. *Nicolai* is a tall grower, with extra large flowers. All these average 2–3 ft. in height.

R. elliottiana (Golden Calla).—This has large yellow flowers and spotted foliage. It blooms about August and grows 2 ft. high. Hybrids of this are now in commerce, of which *Mrs Roosevelt* (pale yellow) is one of the best.

R. Pentlandii has large yellow flowers and unspotted leaves. It is summer flowering, and grows 2 ft. high.—J. J. & E. T. E.

ARUNCUS.—Now included in the genus *Spiraea.*

ARUNDINARIA.—See *Bamboos.*

ARUNDO (Reed. Nat. Ord. Gramineæ).—This is a genus of plants of no great garden value. *A. Donax,* the Provence Reed, is sometimes grown in the wild garden, shrub border, or water garden, under the impression that it is the Pampas Grass (see notes on *Cortaderia* and *Ornamental Grasses*). It flowers much more freely than the last named, though not nearly so elegant, and grows 9–12 ft. in height.

ASAGARA (*Halesia hispida*).— See *Shrubs.*

ASARINA. — Now included in the genus *Antirrhinum.*

ASCLEPIAS (Milkweed. Nat. Ord. Asclepiaceæ).—This genus, though a large one, is very little known save to students of hardy herbaceous plants, or those who make a direct speciality of their culture. Some are not hardy, but these we are not dealing with here. The rest are useful, hardy, ornamental plants, though the nomenclature of the species is somewhat confused. They may be used in the border, but the site should be warm and sunny and some winter protection given. Regarding the soil, I am informed they do best in a peaty medium, but, personally, I do not think this is essential. To propagate them, sow seed in the usual way at the usual times for perennials. They may also be increased by division of the roots in the spring,

and may be planted any time from November to the end of March.

What to Grow.—Species are numerous. We recommend any of the following :—

Asclepias amplexicaulis.—A desirable red sort blooming during July, and averaging 2 ft. in height.

A. Douglasii (Syn. *A. speciosa*).—A useful red sort, blooming in September and October, which averages about 24 ins. in height.

A. incarnata.—A reddish-purple sort of no great value, blooming from July onwards, and of similar height to the above.

A. Michauxii.—A useful white sort, blooming at the same time as the last-named, but a little taller.

A. obtusifolia.—This purplish sort is not as pretty as some. It blooms in July and averages about a yard high.

A. phytolaccoides.—Similar to the above.

A. polystachia.—A taller white flowering sort, coming in during July, and averaging 36–42 ins. in height.

A. quadrifolia.—A useful sort with a scent. In colour it may be light purple, reddish, or nearly pure white. It blooms at the same time as the above, but rarely exceeds 15 ins. in height.

A. rosea.—This is a red sort coming in during July. Its height averages about 12 ins.

A. rubra.—Similar to *A. rosea.*

A. syriaca.—Another scented sort bearing purplish flowers in July. Its height varies from 2½–4½ ft.

A. tuberosa.—An attractive tuberous species bearing distinctly good orange flowers during the summer and in September. Its height averages 18–24 ins.

A. variegata. — A purple-white variety not as attractive as the above opening in July, varying from 2½ to 3½ ft. in height.

ASCOMYCETES.—A group of FUNGI. See *FUNGOUS DISEASES.*

ASH.—A name applied to the genus FRAXINUS. See *TREES.*

ASHES OF PLANTS, Analysis of. It used to be the custom to analyse the ashes of crops and supply to the ground, in the form of artificial manures, those chemicals contained in the ashes of the crops. This old-fashioned idea is now fortunately expiring, for chemical research has proved it to be of very little value.

To take an example : The ash of the stem of the Jerusalem artichoke was analysed and found to contain silica. It was assumed, taking the premises above, that if the ash contained much silica the plants would be greatly benefited by an application of soluble silica. Now silica is not easy to obtain in a soluble state, the best known compounds being hydrofluor-silicic acid, — a compound no amateur should handle, — silicic acid, and sodium and potassium silicate. Some sodium silicate was applied to certain artichokes, and some silicic acid to others. But the most careful observation failed to show any difference in size, quality, or bearing capability between the plants dressed with silica and the plants not dressed with it. Countless other examples might be named to show that the ash contents have little to do with the requirements of the plants.

A much better way to find out what our plants need on certain soils is to have the soil analysed, and then conduct experiments with the crops on the land, using various artificial fertilisers. This takes time but is a most interesting and useful work.

Further notes on Experiments will be found in the article *GARDEN EXPERIMENTS.* Every gardener should, we think, make an effort

to conduct at least one simple experiment each year.

ASHES : Their Value in the Garden. Gardeners divide ashes into two groups, wood ashes and furnace ashes. The first group includes all the ashes gained by burning woody garden rubbish, as well as that gained by burning such green material as potato tops, weeds, ivy leaves, etc. These ashes are most valuable for the garden ; they can either be used when digging or trenching in the winter at the rate of a pound per cubic yard of soil ; or when sowing such root-crops as parsnips, carrots, long beetroot, etc., at the rate of 4 oz. per sq. yd. of surface soil. In every case they should be got under cover as soon as they are produced ; if rain falls on them most of the potash they contain is washed out of them, and they are then valueless for crops.

The second group, furnace ashes, includes coal ashes, as well as the ashes produced in coke-burning furnaces. Some people favour the use of these for lightening heavy clay soils ; they may be good for mechanically improving the worst clays ; but we prefer to keep them off the garden soil. The coke or cinder grit they invariably contain does the crops little good, and in some cases scabs on potatoes have been traced to ashes. Ashes, if used at all freely, also make the soil much too porous, with the result that crops become dry very easily in summer and much labour for watering is required.

Furnace ashes are, however, decidedly useful for making rough paths in the garden. But ash paths, since they "pick up" in bad weather, must not be made too freely in the garden.

Furnace ashes form also a very useful medium in which to plunge pot-plants in the summer, since they effectually prevent worms from entering the pots. For this purpose they should be put through a ½-inch riddle to remove clinkers, etc.

See also under POTASH MANURES in *MANURES*.

ASPARAGUS (*Asparagus officinalis*. Nat. Ord. Liliaceæ).—Few crops better repay a good rich soil than this, a fact which needs to be kept in mind by all when first forming new beds.

The old system of raised beds is now recognised as being superfluous, excepting where the soil is of a very retentive nature, in which case plenty of old builders' rubbish, or clinkers, should be buried not less than 3 ft., below the surface of the bed. The width of the bed is usually from 3 to 4 ft., and when preparing new sites, manure from well-fed horses or cows should be aimed at. A good dressing of old mortar is an advantage to most soils at the time of preparation. Start work as early in the winter as circumstances allow, but defer planting till early spring.

A bed 3 ft. wide will take two rows of plants, allowing each to be a foot from the outer margin. A bed 4 ft. wide will take an extra row, but such a bed will require plenty of help in the shape of rich top-dressings if the produce is to be of the highest quality. Set each plant about 12 or 18 ins. from its neighbour, the distance being decided by the age and size of the plant, also the richness of the bed, a poorly made bed needing more plants. Bury the crowns 3 ins. deep.

No cutting should be attempted the first year, and only very little the second year after planting. Give plenty of clear water if a dry period follows the planting, and

keep the bed free from weeds. The second year, instead of clear water, use liquid manure very freely from May until the end of August. Abundance of excellent asparagus should then be forthcoming during April, May, and early June of the third year from time of planting if one or two year old crowns are set. Cutting should cease after the middle of June, at which date a heavy dressing of rich manure should be given, and manure-water or other liquid fertiliser given liberally during the following ten months. If this is done, the one-time popular method of applying manures in early spring may be dispensed with, though a good dressing of common salt, or Nitrate of Soda in March (3 oz. to the square yard), will be an advantage. Cut away all foliage early in November.

If it is preferred to raise the plants at home, sow the seed in single pots, or in the open air in March, setting each seedling 9–12 ins. apart. Such plants may be transferred to permanent beds the following year.—F. R. C.

See also under *ORNAMENTAL VEGETABLES*. For METHOD OF BOTTLING see *VEGETABLE BOTTLING*.

ASPARAGUS BEETLE.—See *INSECT PESTS*.

ASPARAGUS FERN.—See *ASPARAGUS PLUMOSUS*.

ASPARAGUS FLY. — See *INSECT PESTS*.

ASPARAGUS KALE.—See *BORECOLE, or KALE*.

ASPARAGUS PLUMOSUS (ASPARAGUS FERN. Nat. Ord. Liliaceæ).—This is one of the best and most useful plants either in pots or planted against a wall as a decorative plant, or for cutting purposes, and will keep fresh in water for a long time after being cut. It is propagated by division or seeds in spring, in good turfy loam, leaf-mould and sand, and succeeds well in a temperature between 45° and 60° F.

Greenhouse Species.—*Asparagus myriocladus*.—Whitish-green. Long erect feathery fronds. Flowers from June to September. Height, 1½–3 ft.

A. plumosus (ASPARAGUS FERN). —White. Flowers from May to September. Height, 1–1½ ft.

A. p. scandens.—White. A trailing plant for walls. Flowers from May to September. Height, 2–10 ft.

A. Sprengeri. — Whitish-green. Suitable for hanging baskets. Flowers from June to September. Height, 1–6 ft.

A. tenuissimus. — Light green. Suitable for trailing or for pots. Flowers from May to September. Height, 1–6 ft.

ASPARAGUS RUST. — See *DISEASES OF PLANTS*.

ASPECT FOR ORCHARDS.—See *ORCHARD: MAKING AND MANAGEMENT OF*.

ASPECTS FOR WALL TREES.—See *FRUIT CULTURE: HARDY*.

ASPEN (*Populus tremula*).—See *TREES*.

ASPERUGO (GERMAN MADWORT. Nat. Ord. Boraginaceæ).—This is a genus of hardy annuals of no value in the garden. The best-known sort is *A. procumbens*, or GREAT GOOSE-GRASS, a troublesome weed in some districts. This must be carefully distinguished from ordinary GOOSE-GRASS (*Galium Aparine*), a much more common annual described in our article on *WEEDS*.

ASPERULA (WOODRUFF. Nat. Ord. Rubiaceæ).—One species of this is a hardy annual, and this is the Syrian *Asperula orientalis* (Syn. *A. azurea*). It grows about 1 ft. high, and its slender stems are furnished with small green leaves in whorls of eight. The small light

blue flowers are abundantly produced, and they have the additional virtues of fragrance and longevity when cut and placed in water. It is easily grown in ordinary garden soil from seeds sown thinly in March or April. It is a charming plant, but not nearly so well known as it deserves to be.

Rock Garden Species. — Three species of this genus may be selected for the rock garden, the others are too aggressive. Propagate by dividing the roots in autumn or spring.

Asperula hirta.—Leaves in whorls of six, closely set on wiry stems. Flowers white, changing to pink. Site sunny. Soil gritty. Flowering Period, June to September. Height, 4 ins.

A. nitida (Syn. *A. Gussoni*).—Leaves in whorls on short stems forming dense cushions of dark green. Flowers white. Site sunny. Soil gritty. Flowering Period, June to July. Height, 2 ins.

A. suberosa (Syns. *A. Athoa* and *A. arcadiensis*).—Leaves in whorls, very hairy, close tufts. Flowers pink. Site sunny. Soil gritty. Flowering Period, May to July. Height, 3 ins.

See also WOODRUFF in *MEDICINAL HERBS.*

ASPHODEL (*Asphodeline* and *Asphodelus*. Nat. Ord. Liliaceæ).—The two genera just named, both of which are popularly known as Asphodel, may conveniently be treated together. Both are hardy perennials and may be grown in any soil of average quality. They may be put to the usual purposes, and are propagated by seeds and root division in the usual way in the spring. They may be planted in March.

What to Grow.—We recommend the following :—

Asphodeline liburnica.—A yellow vivid summer flowering sort, averaging 20–24 ins. in height.

A. lutea.—This also is yellow, and flowers about the same time as the above. It is about the same height, though sometimes it reaches as much as a yard.

A. taurica.—This is whitish, but otherwise similar to *A. liburnica.*

A. tenuior.—A yellow sort blooming in July, and 2 ft. in height or thereabouts.

Asphodelus acaulis. — A useful pinkish species of the second genus named above, flowering in May and June, and averaging 15 ins. in height.

A. fistulosus tenuifolius.—A white July blooming sort, averaging 24 ins. in height.

A. ramosus.—There are various varieties of this which are white and bloom from April to August. *A. r. intermedius* is only half-hardy and should be wintered indoors. The height averages 2–5 ft.

ASPHODELINE.—See *ASPHODEL.*

ASPHODELUS.—See *ASPHODEL.*

ASPIDIOTUS.—See OYSTER SHELL BARK SCALE in *INSECT PESTS.*

ASPIDISTRA (PARLOUR PALM. Nat. Ord. Liliaceæ).—This is a useful ornamental foliage plant for rooms, greenhouse or conservatory, and of easy culture, with the flower scarcely discernible showing above the soil like a little round shield. It is increased by divisions in spring, inserted in light loam, leaf-mould and sand. Temperature needed 40–45° F.

Greenhouse Species. — *Aspidistra lurida.*—Brown. Flowers in May. Green leaves 1–2 ft. in length. Height, 1–2½ ft.

A. l. variegata.—Brown. Flowers in May. Variegated leaves 1–2 ft. in length. Height, 1–2½ ft.

ASPIDIUM. — For the best species and varieties see *FERNS AND FERN GARDENING.*

ASPLENIUM.—For the best species and varieties see *FERNS AND FERN GARDENING.*

ASSES' FINNOCHIO (*Foeniculum piperitum*).—See *FOENICULUM.*

ASSIMILATION.—See under FOOD SYNTHESIS in *PLANT PHYSIOLOGY.*

ASSISTING GERMINATION.—Hints on this matter will be found in *GERMINATION OF SEEDS.*

ASTER (STARWORT. Nat. Ord. Compositæ).—Hardy herbaceous perennials and half-hardy annuals. The former range from 1½–6 ft., and the latter from 9–24 ins., in height. A deeply worked well-manured garden soil suits them. They are propagated by seed, division of roots and cuttings.

Cultural Notes.—The true Starworts or MICHAELMAS DAISIES are hardy herbaceous perennials and form the most important section of a widely varied species of plants bearing this name; but the Chinese Asters, also known as *Callistephus hortensis*, which are annuals, likewise fall under the heading of florists' flowers. The perennials are usually increased by division of roots, more rarely by cuttings. They are very useful plants for supplying cut flowers in autumn, and make handsome beds where these can be devoted entirely to different varieties of Starworts.

Starwort Sections:[1]—The various sections have distinct characteristics as follows:—

Aster acris.—Type, starry lilac blue flowers. Height, 2–3 ft.

A. Amellus (ITALIAN STARWORT).—Dwarf growing, with broad hairy leaves. Flowers rather large, varying in colour from pink to violet. Height, 2–2½ ft.

A. cordifolius.—Small, starlike flowers, lilac to white. Very free flowering. Height, 3–4 ft.

A. diffusus.—Medium, flowers white, tinted red. Height, 2½ ft.

A. ericoides (or more correctly *A. multiflorus*).—Heath-like foliage, tiny white flowers, very free and graceful. Height, 2½ ft.

Aster Novae-Angliae (NEW ENGLAND STARWORT).—Flowers large, crimson, purple, and pink. Foliage downy. Height, 4–5 ft.

A. Novi Belgii (NEW YORK STARWORT).—Large flowers freely produced in many shades, including white, lilac, purple, blue, and pink. Strong and tall, growing up to 6 ft.

Varieties.—These are very numerous, and in making a selection the grower should procure a list from a specialist.

CHINA ASTERS are half-hardy annuals; in height they range from 9 ins. to 2 ft. Propagation is by seed sown in March.

Culture.—Seedlings should be carefully thinned out as soon as large enough, and later transplanted into a cold frame. This ensures dwarf and sturdy growth before the plants are finally placed in their flowering quarters about the middle of May, prior to which they must be well hardened off. China Asters make effective bedding plants, and are also grown for conservatory decoration in late autumn. For this purpose seed is sown outdoors in May or June and the young plants potted up just before coming into bloom in September.

Varieties.—Chrysanthemum-flowered, Comet, Ostrich Feather, and Victoria. Each of these may be had in any selected colour.—J. L. G.

[1] Other species suitable for general border work are:—*A. grandiflorus*, the CHRISTMAS DAISY; *A. Linosyris*, well known as GOLDILOCKS; *A. tanacetifolius*, the DAGGER FLOWER; *A. Tradescanti*, the MICHAELMAS DAISY; and *A. Tripolium*, the SEASIDE ASTER. The species described are, however, much more desirable than any of these.—EDITOR.

NEW VARIETIES.

Aster alpinus Nancy Perry.—This, suitable for rockwork, bears light blue flowers having a yellow disc, and grows 6 ins. high.

A. Amellus Arethusa.—This has deep rose flowers, and grows 2 ft. high.

A. Amellus King George.—This has bright violet-blue flowers, and is of very branching habit. Its height is a yard.

A. Amellus Mrs Perry.—This has violet-purple flowers, and grows a yard in height.

A. Novae-Angliae Purple Prince.—This is a dark purple seedling from *William Bowman.*

A. Novi Belgii Blue Gem.—This is a very floriferous dark blue double sort.

A. Novi Belgii Brightest and Best.—This has pretty, semi-double, deep purplish-rose flowers.

A. Novi Belgii Cloudy Blue.—This has double lavender-blue flowers.

A. Novi Belgii J. S. Baker.—This is a free blooming and branching variety, with pure white, semi-double flowers.

A. Novi Belgii Joan Vaughan.—This is an early blooming sort bearing silvery-mauve double flowers.

A. Novi Belgii King of the Belgians.—This bears very large, mauve, semi-double flowers.

A. Novi Belgii Mons.—This bears rosy-red flowers on tall stems, which branch freely.

A. vimineus Lovely.—This bears small pink flowers, which are carried in great quantities on twiggy branches.—W. J. C.

ASTER: Rock Garden Species.—Of these there are only one or two. They thrive in well-drained loamy soil and are propagated by division of the roots in autumn and spring or by seeds sown in March and April.

Aster alpinus (BLUE MOUNTAIN DAISY).—Leaves dark green, entire, in rosettes. Flowers in typical species deep purple. Site open. Soil sandy loam. Flowering Period, June to July. Height, 6 ins.

A. a. albus.—Flowers white.

A. a. ruber.—Flowers deep red.

A. subcaeruleus.—Leaves in rosettes, the whole forming close mats of foliage. Flowers bright purple, with yellow disc. Site open. Soil deep loam. Flowering Period, June to July. Height, 1 ft.

ASTER BIGELOVII.—See *BIGELOW'S ASTER.*

ASTER, CHINA.—See *ASTER.*

ASTER, PERENNIAL.—See *ASTER.*

ASTEROCEPHALUS.—Now included in the genus SCABIOSA.

ASTEROTHRIX.—Now included in the genus LEONTODON.

ASTILBE (Nat. Ord. Saxifragaceæ). The cultural remarks under *SPIRAEA* apply equally to this genus, which is so closely allied to the other that in our opinion both should be united. Hybrids are numerous and beautiful, but it is impossible to describe any here, since these plants are being so rapidly improved that any selection would be quickly out of date. The species described below are quite the best, and most of them are grown at Kew.

Astilbe Arendsii.—This is not a species, but a series of hybrids of *A. Davidii* (see below).

A. Aruncus.—This is a name applied by nurserymen to *Spiraea Aruncus*, which see.

A. chinensis.—This is a pretty pink summer blooming sort about a yard high.

A. Davidii (Syn. *A. chinensis Davidii*).—This is an exceptionally fine species bearing rose-violet flowers in May and June on plants 3–4 ft.

high. The popular ARENDSII HYBRIDS, often named as a species (*A. Arendsii*), have been evolved from this. They vary in colour from the palest pink almost to purple, and are splendid border or water garden plants. The blooming period of all extends from May to August if they are well looked after, and the height averages 2–4 ft. The named sorts are so numerous that any selection given here would be quickly out of date. Readers should thus consult the current trade catalogues.

A. japonica (Syn. *Spiraea japonica*). —This is probably the most popular of all, excluding *A. Davidii*, with its pure white flowers in May and June on plants 2–3 ft. high.

A. rivularis (GOAT'S BEARD).—This is a creamy-white sort blooming freely through the summer, and growing, according to its soil and site, 2–5 ft. high.

A. rubra.—This is an attractive rose sort blooming in August, and growing 6 ft. high.

A. Thunbergii.—This is a white summer blooming sort only about half a yard in height, or at the most not more than 2 ft.

NEW VARIETIES.

Astilbe Princess Mary.—This bears rose and violet flowers in wide pyramidal panicles. It is useful alike for garden and greenhouse.

A. simplicifolia rosea.—This bears rose and white flowers. Its foliage is tinted bronze.

ASTRAGALUS (MILK VETCH. Nat. Ord. Leguminosæ).—A genus of mostly robust plants of little garden value. Three or four species are useful in the rock garden. They thrive in deep sandy loam and are propagated by division in autumn, or seeds in spring.

Rock Garden Species.—We recommend the following :—

Astragalus alpinus.—This has short trailing shoots, forming a mat of foliage. Flowers purple. Site open. Soil loam. Flowering Period, July to August. Height, 3 ins.

A. danicus.—Similar in habit to above. Flowers blue and white. Site open. Soil gritty. Flowering Period, June to July. Height, 3 ins. The variety *albus* has white flowers.

A. massiliensis (GUM TRAGACANTH). —A spiny bush, with silvery pinnate leaves. Flowers white. Site sunny. Soil rocky. Flowering shrub blooming June to July. Height, 1–2 ft.

A. monspessulanus.—Leaves pinnate and in tufts. Flowers large, reddish-purple. Site open. Soil deep gritty loam. Flowering Period, June to July. Height, 6 ins.

See also *SHRUBS.*

ASTRANTIA (Nat. Ord. Umbelliferæ).—This is a useful genus of herbaceous perennials which are of easy culture in ordinary soil, and quite hardy. They may be planted in the borders or in the rock garden, and when once established will look after themselves. They are best propagated by root division in the autumn or spring, and the latter period is the best for planting.

What to Grow.—We recommend the following :—

Astrantia alpina.—Syn. *A. minor*, which see.

A. helleborifolia.—This bears pretty pink flowers in June, and grows about half a yard in height.

A. major (BLACK MASTERWORT). —This is the most popular species of all. It bears pink or red-striped flowers from May to July, and grows 2–3 ft. in height. Two useful varieties of it are *carinthiaca* and *variegata.*

A. minor and *A. pauciflora* are two very pretty species suitable for the rock garden. The first bears

pink and the second white flowers from June to July, and both average 6 ins. in height.

ATHANASIA.—Now included in the genus LONAX. See *EVERLASTING FLOWERS.*

ATHROTAXIS.—For the best species see *TREES.*

ATHYRIUM.—For the best species and varieties see *FERNS AND FERN GARDENING.*

ATLAS CEDAR (*Cedrus atlantica*).—See *TREES.*

ATMASCO LILY.—A name applied to *ZEPHYRANTHES,* which see.

ATRAGENE. — See CLEMATIS in *CLIMBING AND TRAILING PLANTS.*

ATRIPLEX (Nat. Ord. Chenopodiaceæ).—A very large number of species of this genus are quite worthless in the garden. Orache, or Mountain Spinach (*Atriplex hortensis*), to which we devote another article, is grown as a vegetable, but is not admissible in the flower borders. A variety of it, however, *A. h. atrosanguinea,* certainly deserves notice, as the whole of the plant above ground (and sometimes it reaches 6 ft. in height) becomes a rich crimsom-red or red-purple colour. The flowers of this annual are not attractive, but the seed vessels assume the same bright hue as the stems and leaves, therefore this variety is useful for producing colour effects in the wild garden or the bog garden. It is perfectly hardy and easily raised from seeds sown in early spring or late summer. Fifteen inches between the plants will not be too much space for full foliage development.

ATRIPLEX HORTENSIS.—See *ORACHE, or MOUNTAIN SPINACH.*

ATROPA (DWALE. Nat. Ord. Solanaceæ).—This is a genus of hardy herbaceous perennials which are very poisonous and should be banished from the garden unless grown for medicinal purposes. The best known species is *A. Belladonna,* popularly known as BELLADONNA and DEADLY NIGHTSHADE, the culture of which for medicinal purposes is fully described under the first of these names in our article on *MEDICINAL HERBS,* which see. The plant requires handling with care, and children should never be allowed to pluck or handle it.

AUBERGINE.— See EGG PLANT in *SALAD PLANTS.*

AUBRIETIA (PURPLE ROCK-CRESS. Nat. Ord. Cruciferæ).—This is a slow growing, spreading, dwarf perennial, forming carpets of foliage covered in spring with masses of flowers. It is propagated by division of roots after flowering. These divisions planted in a shady border make good plants for the following spring. In the rock garden the plants should be cut back close after flowering to make them grow more compact. There is only one species generally grown :—

A. deltoidea.—Flowers pale purple. Site sunny. Soil rich sandy loam. Flowering Period, April to June. Height, 4 ins. There are many beautiful varieties, including :—*Bridesmaid* (rosy-pink); *Campbellii* (violet-blue); *Dr Mules* (glowing purple); *Hendersoni* (rich purple); *Leichtlinii* (rosy-crimson); and *Moerheimi* (pale rose).

NEW VARIETY.

Aubrietia rosea splendens.—This bears attractive rich rose flowers.

AUCUBA.—For the best species see *SHRUBS.*

AURELIA.—Now included in the genus *NARCISSUS.*

AURICULA : Historical Notes.

This has, in its day, been one of the most famous of florists' flowers. Its history goes back into a period when the student of floricultural lore has an immense amount of material

to draw upon. Without indulging in speculations as to whether it was known to the Romans, for its native home is the Alps, we can certainly trace it back to a starting-point much too remote to allow us to follow up its progress with any degree of detail.

Like many other subjects of the flower garden the Auricula has been known by other names. In old English it was commonly called Bear's Ears, the French and Italian popular names are equivalent, *i.e.* Oreille d'ours and Orecchia d' orso. Bauhin in 1569 named it *Auricula ursi*, from which it is evident that the other names are mere translations. It was so called chiefly from its leaves resembling that animal's ear. Other botanical writers gave it different appellations. For instance, in Mathiolus (1579) it will be found illustrated and described under the name of Sanicle. Clusius (1601) gives several figures of it under the name of *Auricula ursi*, and devotes a whole chapter to it in the third book of his *History of Rare Plants*. John Gerarde in his *Herbal* (1597) devotes chapter cclxii. to an account "Of Beare's eares, or mountaine Cowslips," and there are six wood-cut illustrations of those that he writes about.

A little later John Parkinson in his *Paradisus* (1629) heads his "Chapter XXXIIII. Auricula ursi —Beare's eares." He figures eight varieties on a full-paged plate, giving short particulars of twenty-one kinds followed by notes on the various names under which the flower had been described by other writers, the time of flowering, its habitat and virtues.

John Rea in his *Florilege* (1665) writes an article in chap. xxxi. on "*Auricula Ursi*" which has a distinctly florists' flavour about it. By this time new seedling varieties had evidently been raised and named. He mentions among those early growers "my very good friend, Mr. John Downham, a reverent Divine, and an industrious florist." The clergy of this country, of France and Italy, were then as now eminent in their attachment to flowers. Mr Austen in Oxford, Mr John Good of Balliol College, William Whitmore, Esq., Mr Rickets of Hoxton, and Jacob Bobert of Oxford are all referred to in this connection, and several fantastical names had been bestowed upon the novelties which the raisers had obtained, a sample of this seventeenth-century floral nomenclature being the Fair Virgin, the Matron, the Alderman, Mercury, and a white one called the Virgin's Milk.

As time went on and the cultivation of the Auricula increased and was subjected to the severe rules of the standard set up by the florists, so the literature at home and abroad developed. It is a very voluminous subject and one must be a specialist to understand and absorb it.

In the North of England and Midland Counties the culture of the Auricula among the weavers and artisans became quite a mania. The many shows and continued development of the flower can only be followed up by reference to the periodical horticultural press, which we must pass over as well as the names of the pioneers and champions of Auricula culture who were actively engaged in the work of improvement.

On the Continent, especially in Flanders, the Auricula was much appreciated and widely grown by enthusiasts. Its properties were clearly defined, and there, as in England, the raisers of new seedlings vied with one another in producing flowers that came up to the standard demanded by the exhibitors. In

one old treatise printed in Brussels in 1732 the names of the most famous growers of the day are given with their places of residence. The reader will not fail to notice that many of these places have since become notorious by virtue of the prominent part they played in the Great War, 1914–18.

The Auriculas when in bloom were usually staged in pots on stands, called *Theatres*, and the writer of the treatise already referred to tells us that between 20th April and 10th May is the period when the flowers can be seen at their best. The names of the foremost growers are given at Abbeville, Amiens, Cambrai, Chauny, Douai, Haarlem, Laon, Lille, Mondidier, Nesle, Noyon, Paris, St. Quentin, Soissons, Val St. Pierre, Ypres, and other places.

Samuel Gilbert in his *Florists' Vade-Mecum* (1682) gives descriptions of some of those varieties mentioned by Rea. He says under the heading of "Auriculas—Bear's ears, flowers so much now in esteem (and well deserve it) for their diversity of colour and different faces, each adding a new grace to its kind."

There are many famous names of growers in connection with this flower, but we have no space to mention them. The North of England and the Midlands furnished many of them for a long period of time. It is curious too how long-lived some of the favourites were, for *Page's Champion* was one that until quite recent times was well known by the fancier and had been grown for about a century. Some of the green-edged show varieties were very famous. There were *Slater's Cheshire Hero*, *Taylor's Victory*, and many more beside.

Maddock the great Quaker florist of Walworth, followed Thompson of Newcastle and Hudson of the same town with one of the first of the serious treatises on Auricula culture. This was in 1792. It is really wonderful to notice at that time the large number of florists there were who were occupied with cultivating this flower, for sale and exhibition. The plants were sold at prices varying from a shilling each to about three guineas—that being the price asked for *Maddock's Invincible*. The most famous raisers of that day were Buckley, Bury, Chorlton, Clegg, Foden, Gorton, Grimes, Harrison, Maddock, Metcalfe, Potts, Slater, Stretch, Taylor, etc. Collections of 300 plants named, two plants of each, were offered at £35. Smaller collections proportionately less, down to 25 plants unnamed at 10s.; the best Auricula seed fetched ten guineas the ounce.

Isaac Emmerton was the first author of an independent treatise on the flower—the first edition appeared in 1815. Thomas Hogg of Paddington was another well-known author and practical cultivator whose work on florists' flowers (1820) included a treatise on the Auricula and ran through quite a number of editions.

The flower is essentially a poor man's favourite, hardy and requiring but little space; it is one of the choicest of our florists' flowers. On the show table it is an exquisite little gem, forming a dainty contrast to some of those colossal and gorgeous show flowers like the Dahlia and its sister rival the Chrysanthemum.

In later years there have been many eminent amateurs, besides nurserymen, who have specialised in the Auricula. Messrs. Lightbody, Groom, Horner, C. Turner, and others have all done good work in connection with the flower, which to-day has its interests looked after by an organisation known as the National Auricula and Primula Society, at the exhibitions of which

the reader can feast his eyes upon some of the most delightful floral gems that Nature, aided by the art and patience of man, has ever yet produced.—C. H. P.

AURICULA (*Primula Auricula.* Nat. Ord. Primulaceæ).—Hardy perennial. Height, 6–9 ins.

Soil.—Well-drained, heavy loam enriched with old manure is suitable for garden or rockery sorts, but the show varieties must be grown under glass to secure protection against the weather. In this case the best medium is two parts turfy loam, one part decayed farmyard manure, and one part half-decayed leaves run through a half-inch sieve, with sufficient coarse sand or crushed oyster shell to keep the soil porous. Propagation is by seed and offsets.

Culture.—Seed can be sown when ripe in July, August, or in spring. Use light sandy soil and barely cover the seed. Germination takes place in ten to fourteen days. Prick out the seedlings as soon as they can be handled, 5 or 6 in a 4½-inch pot, using little or no manure in this compost. In due time pot each plant singly into 2½–3-inch pots according to development, and finally into 4–4½-inch size. Pots of larger size are not recommended, as the flowers are more perfectly developed if the roots are somewhat cramped. Offsets may be taken from the parent plants in spring, and at repotting time in summer. These are usually rooted before separation, and grow into full-sized plants in about two years.

Apart from their value as cold greenhouse plants the Alpine Auriculas are decorative spring subjects for the rockery and for bordering shady beds or edging borders. The main flowering period is throughout April; but blooms will begin to open early in March, and last on through the greater part of May. Occasionally also trusses of bloom will open in autumn.

Varieties. — SHOW AURICULAS:

Green Edged.—Prince Charming, Shirley Hibberd, William Smith.

Grey-edged. — Geo. Lightbody, Geo. Rudd, Richard Headley.

Selfs.—Favourite, Fingo, Harrison Weir.

White-edged. — Acme, Eucharis, Guy Cranfield.

ALPINES:—Argus, Golden Dustman, Firefly, Kaffir, Majestic, Mrs. Douglas, Muriel, Prime Minister, Prince of Tyre, Phyllis Douglas, Roxborough, and St. Vincent.

J. L. G.

NEW VARIETIES.

ALPINE SORTS: — *Edith.* — This bears fragrant flowers having a maroon body, a broad margin of purple, and a yellow eye.

Pilatus.—This has flowers with a blackish-purple body, a silvery-purple edge, and a creamy-white eye.

Silverwood.—This has flowers with a maroon body, a bright crimson edge, and a white eye.

SHOW SORTS: — *Edenside.* — This bears fragrant heliotrope, self-coloured flowers.

Gordon Douglas.—This bears large, fragrant, golden-yellow self-coloured flowers.

AURICULA.—See *Primula Auricula* in *PRIMULA.*

AURINIA.—Now included in the genus *ALYSSUM.*

AUSTRALIAN BRACKEN (*Pteris tremula*).—See *FERNS AND FERN GARDENING.*

AUSTRALIAN GUM TREE. — See *EUCALYPTUS.*

AUSTRIAN BRIAR (*Rosa lutea*).—See *ROSE SPECIES.*

AUSTRIAN BRIAR ROSES. — See *ROSE CLASSES.*

AUSTRIAN HYBRID ROSES.—See under PERNETIANA ROSES in *ROSE CLASSES*.

AUSTRIAN PINE (*Pinus Laricio nigricans*).—See *TREES*.

AUTUMN BLOOMING ROCK PLANTS. See ROCK PLANTS FOR AUTUMN BLOOMING in *ROCK PLANTS FOR ALL PURPOSES*.

AUTUMN CROCUS (*Colchicum autumnale*).—See *COLCHICUM*, also under CROCUS in *MEDICINAL HERBS*.

AUTUMN-FLOWERING BULBS (for the Rock Garden).—See *ROCK GARDEN BULBS*.

AUTUMN-FLOWERING CROCUSES. See under SPECIES AND VARIETIES in *CROCUS*.

AUTUMN GARDEN : THE.

Few people are not struck by the beauty of the autumn garden, with its grass, and flowers and plants spangled with September dews, and its glorious colours. Only, however, are the autumn days too short, the evenings soon draw in, and outdoor gardening in the evenings is greatly curtailed. The leaves fall from the trees, making a "litter," and the autumn winds blow sadly, though sometimes fiercely around, and the fact that winter is fast coming on is again and again forced upon us. I am not myself nearly as fond of the winter as the summer,—for, of course, the summer time is the active time and the beautiful time in the garden,—and this feeling is shared by many people, who also dislike the long wet winters we have, but certainly at these seasons there is much that can be done if the results next spring and summer are to be good.

However, I am rather wandering from my subject. The present article is not about the winter garden, but about the autumn garden.

Tidying Up.—Of course, gardeners say it is their first duty to do tidying up as the autumn season comes on and passes. And such is very necessary on big places where there is much in the way of trees and pleasure grounds. Nothing looks worse than a large lawn semi-covered with rotting leaves. Nothing pictures lack of care and pride in the garden as much as herbaceous borders from which the dead remains of plants have not been removed, but have been allowed to remain decaying for three or four weeks. In the autumn season weeds go to seed and the same unkempt and uncared-for appearance results if they are not rooted out of borders and paths. So, in a word, it is a most necessary thing to do to tidy up.

In the Woodland.—But while tidying up is essential if the pleasure grounds are to look as they should, it would be a waste of time and indeed bad policy to spend hours in the woodland brushing up the leaves as they fall, as some people do. In these days of expensive labour, and labour so hard to get withal, gardeners and gardening folk should not tidy more than need be. For after all, the woodland is the woodland, and it is here that the autumn effects are so beautiful. Here also Nature may be left to her own will, tidying up being done if necessary when the winter has come. Leaves are, of course, the natural food of the soil of the woodland, and should not be swept up more than necessary.

If the leaves from the trees in the pleasure ground are to be used for the purpose of leaf-mould, then pine needles and "acrid" leaves must be kept out. Some say that only oak and beech leaves should be used, but most of us have not enough of these to supply our wants, and so use others as well. Leaf-mould is made best by stacking the

leaves in the open and covering with a good weight of stable manure.

Planning Next Year's Garden.—Ere it is too late to notice them, the plants which are not in suitable positions in the borders should be marked and new positions decided upon and pictured if possible in a plan.

But, of course, much other actual planning can be done. Readers can well use the long autumn and winter evenings by making plans of new borders, blue borders, yellow borders, red borders, "annual borders," "perennial borders," and also, of course, structural alterations. Such plans should be well thought out, and will be ready to put into practice in the late winter or next spring. Many people, as has so often been pointed out, make up their minds and do alterations all in a hurry, and then they wonder why they are disappointed by the ill effects. Gardening, like other occupations, needs a vast deal of thought if good effects are to be produced, and it is in the autumn and winter months that new plans can be given that all-important thought.—E.

AUTUMN HARVESTING. — See *ALLOTMENTS: MANAGEMENT OF.*

AUTUMN SOWING: Some Views on.

Much has been said and written about the sowing of annuals in the autumn, but perhaps a short article may be useful to readers of the Dictionary who it is possible have not seen the correspondence about it in the Press recently.

Personally I am not in favour of autumn sowing, at any rate in cold northern districts where the garden is exposed to winds which sweep down from the moors or hills, and an extensive trial with certain well-known hardy annuals showed the plants to be weak and spindly at the end of the winter. But I am quite willing to consider both sides of the question, and any who have sheltered borders would do well to try autumn sowing, as there is no doubt that when it "comes off" the results the following summer are highly enviable.

Certain plants are much hardier than others. Such strong annuals as *Calendula officinalis*, the Clarkia, the Feverfew (this last is, however, a weed in most gardens near here), the Godetia, and the Shirley, or the Common Poppy, are examples, but there are many others quite as hardy. All come very readily when they sow themselves naturally in their own way at the end of the season. Many of these seeds never germinate till the spring, so they miss the cold winter above ground. We have, for instance, some Calendula growing at the edge of the border with splendid blooms on, and this has sown itself from some plants set the previous season. The same with poppies. They sow themselves readily and appear where not required—that is no uncommon occurrence. I have found with several annuals that they come up all right if left to themselves, but not nearly so satisfactorily if one takes trouble to sow them.

This fact suggests an idea which may seem comparable to laziness. If self-sown annuals come up so well, why not let them be self-sown and pull up the old plants in the winter or next spring? Such a proceeding I would not commend, but I believe it has been seriously suggested many times before this. It is evidently not desirable for the following good reasons: (1) Because the soil cannot be dug up and manured meanwhile; (2) because the seedlings are likely to come up somewhat irregularly; and (3) because this necessitates the land being cropped with the same plant for at

least two successive seasons. Other reasons may occur to the reader.

People will say that all these reasons are to be disannulled. Taking the first one they will ask, "Why should not the soil be dug and manured? Your wild poppies and feverfew come up irrespective of that." Yes they do, but they are not wanted, and as aforesaid the seed may fall into the ground too late to germinate the same autumn. Moreover, we can truthfully say that the vitality of the seeds of most of our weeds bids fair to be greater than that of any other seeds known; it must be, or they could not exist. And if the garden be dug over at all correctly, the surface layer of the soil containing the seeds will be buried at least 9 ins. The seeds of our shier garden flowers, and indeed those of the hardier of the annuals, cannot be expected to come through that.

The second danger given above is not so great, but nevertheless it is quite serious enough. It is admitted that the spring-sown annuals have to be thinned out, and thinned out mercilessly. But the danger is on the other side. We can thin out excessively thick seedlings;—indeed, we must do this somewhat heart-breaking task as soon as ever the plants are large enough, be that in the autumn after they have appeared or next spring, but—and this is a very big "but"—we can expect no success if we try planting out the "thinnings" on the bare spaces on which the seed has unluckily not fallen.

Again, however, the reader may exclaim, "Why not sow some seeds on the bare spots in the spring, or why not plant something else there when bedding-out time comes?"

But as to the former we have already said that spring-sown ones are always later than successful autumn-sown ones, so the gap in the group of annuals is still apparent; and with regard to the latter, the planting of such spots to harmonise with the surroundings is not far from impossible, if the bare spaces be towards the back of the plot containing tall annuals.

The question of rotation is not considered by many who are really serious flower gardeners. But the principle which I will state directly is almost essential to the prolonged success of the vegetable garden, and I see no reason why it should not apply to flowers as well. Broadly, the principle of Rotation of Crops states: "That every particular crop takes from the land a certain particular compound necessary and essential for that certain plant's development, and, that if a given piece of land be cropped for many successive years with one certain crop, irrespective or almost irrespective of the fact that the land is manured once a year, that piece of land will become impoverished of the certain compound necessary for the plant, and that the plant will cease to flourish there in consequence."

Of course two successive years or even more would be much less serious if the land was properly manured than if it was not, but it is far better to change the land given even for certain flowers each year if at all reasonably possible. Hence our third reason for avoiding this practice.

Up to this point we have remarked on the self-sowing of annuals freely, and we have decried it. I have already said that I myself do not care for autumn sowing of annuals at all, but those in other warmer parts of the country have by one means or another obtained the following all-desired results: (*a*) Strong plants, (*b*) flowers much

earlier than spring-sown annuals, (*c*) flowers of better quality. [This last is, I fancy, only occasionally, seeing what excellent results we get from spring-sown annuals.] (*d*) A prolonged supply of bloom most of the summer if the plants are attended to and the seed vessels removed, and (*e*) seed if to be saved can be had in plenty, of good quality, and is ripe early.

Such advantages as these are, of course, likely to tempt the gardener, but whether the game is worth the candle—what with the risk of loss of seed, etc., in each particular case—this fortunately is not my business to decide.

But if, as said before, it "comes off," splendid plants are often obtained (these, of course, by sowing the seed in a prepared bed as described hereafter). I have read that plants of Clarkia and Godetia, especially when autumn sown, sometimes form bushes a foot across, and I do not doubt this. Specimen plants of annuals of that size must be truly fine when in full bloom.

So I do not urge people not to try autumn sowing. It will, I admit, produce great results in good positions; but what I do say is that those whose gardens are exposed to all the cold winds which blow may save themselves the trouble and disappointment of trying autumn sowing.

We will now give a brief résumé of the practical details connected with autumn sowing, since to close an essay on autumn sowing without giving these seems to me somewhat absurd.

Last year a new idea was told me when it was too late to try it, but I hand it on in case some readers may not know it.

The gentleman I was talking to referred to autumn sowing, and he said, "The new idea is to sow the seeds on a north border." The prevailing idea, that the north border is the coldest one in the garden, here seems mistaken. My friend explained that if the north border gets frost, it at any rate gets very little sun, and at times it is the sun after frost which does the damage. As I have not tried this I can only give what I am told. But I should think it inadvisable to try the experiment on a north border which is also open to cold east winds.

The more usual way of proceeding is to choose a piece of land adjoining a wall facing due south. The desirability of its being sheltered from the other points of the compass is generally accepted. The land is dug over and has some rotten manure incorporated *deeply* into it; no surface manuring should be allowed. Then the land can be levelled and permitted to settle for some days, after which some old soot may be forked in at desire, and the surface raked fine. Sow the seeds very thinly in beds, lines, or clumps, and cover lightly with soil. Label accurately. Thin as soon as possible, and in cold weather it is advised to cover the bed with hand-lights, supported mats, or straw, removing these as soon as the danger is past.

AUTUMN WEEDING.—See *ALLOTMENTS: MANAGEMENT OF.*

AUVERGNE PINK (*Dianthus arvernensis*).—See *DIANTHUS.*

AVENA (OAT. Nat. Ord. Gramineæ).—This genus is not of much importance to the gardener, but of great importance to the farmer, as Oats are one of its species (*A. sativa*). The best species for the garden is *A. sterilis*, the ANIMATED or WILD OATS described in our article on *ORNAMENTAL GRASSES.* It is known at Kew as *A. fatua.*

AVENS.—A name applied to *GEUM* which see.

AVENUES.

The planting of avenues of trees is a garden operation which is, alas, on the decline. Avenues look so stately and noble that it is a great pity to let the practice drop. There should, of course, be some definite object at the far end of the avenue, such as a house, tower, monument, or the like. Elms, Oaks, Horse Chestnuts, and many other trees are suitable for avenue planting, and Limes look very well, but by far the most striking effect is produced if the avenue be made of Copper Beeches.

AVERAGE GERMINATION OF SEED.

See *SEED : AVERAGE GERMINATION OF.*

AYRSHIRE ROSE (*Rosa arvensis*).—See *ROSE SPECIES.* For the best varieties see *ROSE CLASSES.*

AZALEA[1] (Nat. Ord. Ericaceæ).

Very beautiful free flowering shrubs. The Indica hybrids with single and double flowers are quite indispensable for decorative purposes, from January to May. They are propagated by cuttings of half-matured wood in spring, and should be potted firmly in good peat and silver sand. The cuttings should be placed in a temperature of 55° F., under a bell-glass or hand-light. Temperature needed when potted 40–50° F.

Greenhouse Species.—*Azalea amoena.*—Crimson-purple. Flowers in April. Height, 1–2 ft.

A. balsaminaeflora.—Salmon-red. Flowers in April. Height, 1–2 ft.

A. indica (INDIAN AZALEA).—Scarlet. Flowers in May. Height, 1–2 ft.

A. linearifolia.—Rose. Flowers in March. Height, 1–2 ft.

A. obtusa.—Red. Flowers in March. Height, 1–2 ft.

A. ovata.—Pink. Flowers in April. Height, 1–2 ft.

A. o. alba.—White. Flowers in April. Height, 1–2 ft.

A. rosaeflora.—Rosy red. Double. Flowers in March. Height, 1–2 ft.

Good Indica Hybrids.—*Azalea Apollo.*—Double scarlet. Flowers from January to May. Height, 1–2 ft.

A. Deutsche Perle.—Double White. Flowers from January to May. Height, 1–2 ft.

A. Hermosa.—Bright rose. Flowers from January to May. Height, 1–2 ft.

A. J. T. D. Llewellyn.—Rose with red markings and white border. Flowers from January to May. Height, 1–2 ft.

A. Mdlle. Marie Rosseel.—Flesh coloured. Flowers from January to May. Height, 1–2 ft.

A. Vuylstekeana.—Brilliant crimson. Flowers from January to May. Height, 1–2 ft.

AZALEA : Hardy Species.

As a general rule no culture distinct from that given to Rhododendrons is required by these species, though they are often used for more select purposes. The following species, which we recommend as being distinct, include all the best hardy Azaleas. The greater number of the synonyms have been purposely omitted for the sake of simplifying the list, and reference should be made to nurserymen's catalogues for varieties of garden Azaleas commonly sold as GHENT AZALEAS. For convenience of reference the names of the Rhododendrons under which these Azaleas appear in the *Kew Hand-list of Trees and Shrubs* are added. The heights given are approximate only.

[1] This is now correctly included in the genus *RHODODENDRON* (see separate article), but in gardens the two are still regarded as distinct genera.—EDITOR.

Azalea arborescens (Syn. *Rhododendron arborescens*). — Red flowers in June. Height, 10–20 ft.

A. calendulacea (Syn. *Rhododendron calendulaceum*).—Orange flowers in June. Height, 2–8 ft.

A. californica (Syn. *Rhododendron californicum*).—Purple flowers in May or June. Height, 2–8 ft.

A. indica (Syn. *Rhododendron indicum*). — The INDIAN AZALEA. See above under GREENHOUSE SPECIES. The variety *balsaminaeflorum* (Syn. *A. rosaeflora*) is hardy and has salmon flowers in May. Height, 1 ft.

A. ledifolia (Syn. *Rhododendron ledifolium*).—White flowers in June. Height, 2–6 ft.

A. linearifolia (Syn. *Rhododendron linearifolium*). — Rosy-lilac flowers in May. Height, 1–2 ft.

A. mollis in variety (Syn. *Rhododendron sinense*).—Flame-red flowers from May onwards. Height, 3–6 ft.

A. nudiflora in variety (Syn. *Rhododendron nudiflorum*). — The PINXTER FLOWER. Pink or white flowers in April. Height, 3–4 ft.

A. occidentalis (Syn. *Rhododendron occidentale*).—White flowers in May. Height, 2–6 ft.

A. pontica in variety (Syn. *Rhododendron flavum*).—Yellow flowers in May and June. Height, 4–6 ft.

A. Vaseyi (Syn. *Rhododendron Vaseyi*).—Pink flowers in April. Height, 2–4 ft.

A. viscosa (Syn. *Rhododendron viscosum*). — The SWAMP HONEYSUCKLE. Pink flowers in May and June. Height, 2–4 ft.—S. A.

See also *RHODODENDRON*.

AZALEA LEAF BLISTER. — See *DISEASES OF PLANTS*.

AZALEASTRUM (FALSE AZALEA. Nat. Ord. Ericaceæ).—This is a group of Rhododendrons requiring the general culture outlined in the article on *RHODODENDRON*. The best species are *Rhododendron albiflorum*, with its white flowers in June on plants 2–3 ft. high, and *R. ovatum* with its purple-spotted purplish-rose flowers in May on plants 2–3 ft. high.

AZALEODENDRON. This is only a generic name from the nurserymen's point of view. Botanically it is now a series of hybrids of *Rhododendron sinense*. Many of these are of great value in the garden, and are known as *Azalea mollis Hybrids*.

AZARA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

AZAROLE (*Crataegus Azaroleus*).—See *TREES*.

B

BABIANA (BABOON-ROOT. Nat. Ord. Iridaceæ).—Babianas are half-hardy bulbs, whose native home is the Cape of Good Hope, where they are a favourite food of the baboons. From this circumstance the Dutch colonists gave the plant the name of Babiana: "Babianer" being the Dutch for baboon. As a rule the pale-green foliage is hairy and the flowers brightly coloured, some being blue and some being crimson.

Culture.—It is only in the very warmest parts of the British Isles that outdoor culture can be attempted with any prospect of success, and Babianas should be treated as pot-plants except in such localities. The bulbs may be potted in October, placing about six bulbs in a 5-inch pot. They like a light compost, made up of sandy soil, leaf-mould, and rotten cow manure. A winter temperature of from 40–50° F. suits them. Water should be sparingly

given until the growth has well advanced, when a little help from weak liquid manure is beneficial if given at every other watering. Babianas may be grown from year to year, if after flowering the pots are kept in a warm greenhouse and the plants regularly fed until the foliage begins to turn yellow, when water must be gradually decreased, until the leaves wither, when it must be entirely withheld.

Varieties.—As a rule Babianas are offered in mixture. The colours vary very much—scarlet, crimson, mauve, blue, and purple being available. The best sort is—

Babiana stricta rubro-cyanea.—This has brilliant blue flowers with a basal zone of crimson. It blooms about April, if slowly forced, and grows about 1 ft. in height.

BALLOTA (STINKING HOREHOUND. Nat. Ord. Labiatæ).—This is a genus of herbs and weeds of no garden value, though some are used for herbal medicines. *B. nigra* (Syn. *B. vulgaris*) is probably the best known species. It is popularly known as BLACK HOREHOUND. *B. Pseudo-dictamnus* (Syn. *Marrubium Pseudo-dictamnus*), known by some nurserymen as FALSE DICTAMNUS, or FALSE DITTANY, is another species not unlike a very coarse growing Dictamnus. See articles on *FRAXINELLA* and *MARRUBIUM.*

BALM (*Melissa officinalis*). — See *MELISSA* and *POTHERBS.*

BALM OF GILEAD (*Abies balsamea*). See *TREES.*

BALSAM (*Impatiens Balsamina.* Nat. Ord. Geraniaceæ).—This is a half-hardy annual growing about 18 ins. high. A rich soil with good drainage is required, and abundant moisture must be provided during the growing season. Propagation is best effected by seed.

Culture.—Seed sown in heat in February will produce flowering plants by June, and successional sowings will prolong the flowering season till the autumn. Sandy loam and leaf-mould in equal parts is a good medium for the seedlings. These should be pricked out early, and potted on as occasion demands, till finally the plants are accommodated in 6- or 7-inch pots. A compost made up of maiden loam and decayed farmyard manure in equal parts, with a little leaf-mould or fibrous peat, and some silver sand, will then produce good results in this latter stage. The atmosphere of the house should always be kept moist, or red spider is likely to become troublesome. Frequent fumigation is desirable. See article on *FUMIGATING.*

Uses.—Balsams are splendid for decoration of conservatory or greenhouse, and are sometimes employed for summer bedding out of doors.

Varieties.—Selected strains of seed should be purchased from a well-known seedsman.—J. L. G.

BALSAM FIR (*Abies balsamea*).—See *TREES.*

BALSAM POPLAR (*Populus balsamifera*).—See *TREES.*

BAMBOOS.

The evergreen, woody plants known collectively as Bamboos belong to several genera of the Bambuseæ tribe of the order Gramineæ. Some of the principal genera are :—

Arundinaria, Bambusa, Cephalostachyum, Dendrocalamus, Dinochloa, Gigantochloa, Melocalamus, Melocanna, Ochlandra, Oxytenanthera, Phyllostachys, and *Thyrsostachys.* So far as the British Isles are concerned, however, *Arundinaria* and *Phyllostachys* are the two most important genera.

Habit.—Bamboos vary a good deal in habit, ranging from giant plants with stems 100 ft. high and 9 ins. in diameter, to low-growing species 1½ ft. high with stems of less diameter than a knitting-needle. Allowing for this variation, however, the species of the various genera have certain points in common. For instance, they all spread by means of rhizomes, which may be very short or little more than the production of a growth bud from the parent stock immediately below the ground line, or of considerable length running about beneath the ground after the manner of couch-grass. Old stems, again, are constantly maturing and dying without bearing flowers, new ones taking their place until the age limit or period of maturity of the particular species has arrived, when all the living stems almost at once lose their sterile condition, and with every new one that appears produce flowers, bear seeds, and, as a rule, die. The period of maturity only occurs at long intervals, perhaps in thirty, forty, or more years; then, however, the plants growing over hundreds of thousands of acres usually flower at the same time, seed and die, to give place to a new generation which continues to flourish until in its turn the flowering age is reached. Flowering takes place in the case of cultivated plants as well as in that of plants growing in a state of nature, therefore it behoves the cultivator to collect seeds whenever possible for the purpose of perpetuating his stock, for seedlings enjoy a longer life than plants raised by any other means. Another item possessed by Bamboos in common is the regularly jointed stems, the stems being hollow between the joints and every joint bearing when young an attendant sheath.

Uses.—In tropical countries short sections of the larger stems cut beneath a node are used for plant receptacles, instead of the, to us, more familiar flower-pots, whilst strong stems are in demand for house-building, bridges, fences, and other structural purposes. Smaller stems have considerable value for the manufacture of furniture, stakes, fishing-rods, walking-sticks, etc.; rods split into narrow strips are made into ropes and plaited into mats; young growing joints are used as a vegetable and old stems are macerated and made into paper; the seed is a valuable food grain and has been known to take the place of the commoner cereals in some tropical countries in times of scarcity. These, though but a few of the many varied uses of the Bamboos, serve to indicate the enormous economic importance of the group, more particularly to the residents of tropical countries, whilst they are brought prominently into notice in other countries in many ways.

Bamboos are more characteristic of the arboreal vegetation of tropical and sub-tropical countries than of temperate climes, although there are many hardy species from Japan, a few from China and the Himalaya,

and one from North America. Asia is the great Bamboo-producing continent, India and Burma being the headquarters of the family. Many of the species are of purely tropical origin and are of little value for cultivation in this country, the temperate ones being of greater worth from a decorative standpoint.

In the following notes the culture of hardy and tender species is given under different headings, the descriptions being followed by a selection of hardy and tender species in alphabetical order, each one marked as to hardiness.

Outdoor Culture.—Hardy Bamboos became popular with the garden-loving public during the last decade of the nineteenth century, for, although a few species had been introduced about the middle of the century and grown here and there from that time onward, many more were received from Japan about 1892, and from a few collections formed about that time, a stimulus was given to general planting, with the result that there are now few gardens of importance in the country where Bamboos are not to be found. Unfortunately in the early days a good deal of indiscriminate and injudicious planting took place, with the result that they were at times comparative failures, thereby earning a bad name in some quarters. Bamboos at their best are amongst the most charming evergreens we possess; they are not, however, suitable subjects for every position, and instead of mixing them in shrubberies with other shrubs or including them as isolated lawn specimens in prominent places, they ought, whenever possible, to be given a position to themselves or be grown with such kindred plants as *Arundo* and *Miscanthus*, a little apart from the shrubs. The reason for this is that whilst Bamboos are peculiarly attractive for six or seven months of the year, from July onwards, they are decidedly dingy during spring and early summer when most shrubs are at their best, for the first cold winds of late winter cause the leaves to shrivel and turn brown, a condition maintained until the new leaves develop in June.

When selecting a site for a Bamboo garden choose a semi-shady position sheltered from cold winds but not impoverished by the roots of trees. The banks of a lake or stream often form a charming garden, and the proximity of water is valuable in dry weather. Rich light loamy soil is the most suitable, but success can be attained in heavy loamy soil approaching a clayey nature. Trench the ground and incorporate leaves and manure, cow manure for preference, allow the ground to settle, then in May, or when the new shoots are about an inch long, carry out the planting. Water well and mulch the ground with leaves or decayed manure. Although Bamboos usually grow freely when transplanted in May, they often suffer severely if disturbed at other times. As a rule, if abundance of room is given in the first instance, they will grow for many years without disturbance. It is, however, a good plan to water them a few times during the growing season with liquid cow manure, and to surface the ground above the roots with manure at least every second year. Pruning takes the form of removing each spring some of the older stems, or such as appear to be dying, the work being done during early April. Be careful to remove the growths quite close to the ground line. Never shorten a shoot half-way; if it must be cut, take it clean away.

Propagation should be carried on by means of seeds whenever possible; but as seeds are rarely available,

one of the following methods, division, cuttings, or layers, must be selected. Division means the removal of large or small sections from the parent stock and treating them as separate plants. Large sections can be planted at once in the open ground, but small pieces should be potted and placed in a moist greenhouse until new roots are active. Cuttings are formed of sections of stems one or two nodes, usually two, in length. Roots are formed from the node inserted in the soil, and growth is from dormant buds. This method is not practised much here, but some of the vigorous species in the tropics respond well to this method of increase. Layers consist of pegging shoots down into the soil, a notch being sometimes cut at each node, although this is not absolutely necessary. Roots and shoots appear in due course, which can be removed as separate plants. May is a good time for division and layering.

Bamboos planted in large pots or tubs are useful for the decoration of large rooms in winter, and for this purpose the hardy kinds are more desirable than the tender ones. They can be kept in good health by feeding and proper attention to watering. In dry weather all Bamboos should be given a good supply of water. Cut branches of Bamboos are not of much value for decorative work, as the leaves soon shrivel.

Most of the hardy Bamboos are included in the two genera *Arundinaria* and *Phyllostachys*, *Bambusa* containing one or two species of little value. As they are likely to claim more attention than other genera, the following remarks on their distinguishing characters are appended. *Arundinaria* and *Phyllostachys* are readily distinguished from each other by the following peculiarities:—In *Arundinaria* the side-shoots are in dense clusters of an indefinite number each and the culm or stem sheaths are retained on the stems long after they are dead, whereas in *Phyllostachys* the side-shoots are in groups of three each, two large and one small, the latter sometimes falling away soon after it matures, and the sheaths are very early deciduous.

Indoor Culture.—It is only practicable to cultivate the tender Bamboos successfully in lofty structures where a moist atmosphere can be maintained, and even in those places they ought not to be overdone, for it must be remembered that they have neither attractive flowers nor luscious fruits to recommend them. Nevertheless a few can be admitted to large palm houses and winter gardens with marked success. For winter gardens where a minimum winter temperature of 40–45° F. is maintained all those that come from sub-tropical countries may be grown, the tropical species requiring a minimum 10–15° higher. They may be grown in pots, tubs, or borders, border culture being the most satisfactory. In either case thorough drainage must be provided, and rich loamy soil containing sharp sand and half-inch bones. Keep the plants well watered, and well syringed or hosed overhead, otherwise the leaves will become a prey to thrips and red spider. Prune and propagate as advised for the hardy species. Those grown in pots and tubs will require frequent applications of liquid manure during the growing period.

A CHOICE SELECTION.

Arundinaria.—*A. anceps*, from the North-west Himalaya, has slender, erect branches 12–14 ft. high, and rather small, dainty, bright green leaves. It spreads rapidly and forms picturesque masses. Hardy.

A. angustifolia.—This is a low-growing plant with slender stems 2–6 ft. high, forming dense clumps. Native of Japan. Hardy.

A. aristata.—An elegant plant 8–12 ft. high, from the Eastern Himalaya, suitable for the warmer parts of the country but hardly suitable for general outdoor planting.

A. armata.—A vigorous plant with spiny stems at least 20 ft. high and 1–1¾ in. in diameter. Its leaves are 6–9 ins. long and ¾–1½ in. wide. Native of Upper Burma. Requires a warm structure.

A. auricoma is a Japanese species growing 4 ft. high, with slender stems. The leaves are distinct by reason of their golden variegation. Hardy.

A. elegans.—This is a graceful plant with stems 12–20 ft. high and less than an inch in diameter, the leaves being 4–5 ins. long and up to ½ in. wide. Native of Assam and Burma. Requires a warm greenhouse.

A. falcata is a very graceful tall-growing plant 15–18 ft. high. The stems are grouped closely together, the lower parts erect, the upper bending gracefully outwards. The leaves are usually 3–4 ins. long and less than ½ in. wide, larger on young vigorous shoots. Native of the Western Himalaya. Half-hardy.

A. Falconeri is a closely allied species from the Himalaya. It is rather tender but grows into very attractive specimens in Cornwall and Ireland. It is excellent for cool winter gardens. The stems are used for fishing-rods, basket-work, etc.

A. fastuosa (Syn. *Phyllostachys fastuosa*).—There are few handsomer hardy species than this and none to keep better colour in spring. The strong erect stems exceed 20 ft. in height and are 1½ in. thick. Native of Japan.

A. Fortunei is a dwarf plant from Japan rarely exceeding 2 ft. in height. The leaves are prettily variegated with silver. Hardy.

A. graminea.—An erect, handsome plant 10–12 ft. high, with rich green narrow leaves. Native of Japan. Hardy.

A. Hindsii is closely allied to *A. graminea* but is much coarser in character and less useful.

A. Hookeriana.—A handsome fast-growing plant at least 20 ft. high, with strong stems over 1 in. thick. Leaves 6–12 ins. long and ½–1½ in. wide. Native of Sikkim and Bhutan. Suitable for Cornwall and for a cool winter garden.

A. intermedia.—A vigorous species 12 ft. or more high, with leaves up to 8 ins. long and 1 in. wide. Native of the Western Himalaya. Branches used for baskets, fishing-rods, etc. Can be grown out of doors in Cornwall, but not generally hardy.

A. japonica (Syn. *Bambusa Metake*).—This is perhaps the hardiest and best known of all Bamboos. A native of Japan, it was introduced in 1850. The stems are 12–15 ft. high and the leaves large and attractive. Hardy.

A. nitida is a very dainty species from Central and Western China. Growing about 10 ft. high, it forms dense masses of slender arching stems clothed with the daintiest of pale green leafage. It is one of the most beautiful of all Bamboos but quickly suffers from drought. Hardy.

A. palmata (Syn. *Bambusa palmata*).—This is a vigorous fast-spreading plant with slender but stiff stems 6–8 ft. high, bearing large leaves up to 12 ins. long and 3 ins. wide. Native of Japan. Can be cut down to the ground line every three or four years if desired. Hardy.

A. pygmaea grows from 12–18 ins.

high, with very slender stems which form a dense mass. Native of Japan. Can be cut to the ground every second year. Hardy.

A. Ragamowskii (Syn. *Bambusa tessellata*) has the distinction of producing larger leaves than any other hardy Bamboo. They are sometimes 18 ins. long and 4 ins. wide. It is not a very striking plant, however, and only grows about 3 ft. high. Native of China. Hardy.

A. Simonii is an erect plant from China, with stems 18 ft. long. It is fast growing and often represented in gardens by large masses. There is a variegated form but it is not effective and has no horticultural value. Hardy.

A. tecta is the single hardy species from America. It grows wild in the south-eastern United States, and forms a dense mass of stems 6–8 ft. high. It is not a very effective plant.

Bambusa.—*B. Alphonse Karrii.*—There is some doubt as to the origin of this plant, but it is striking by reason of its stems being striated with gold and green. It is probably hardy in the mildest parts of the country, but elsewhere should be grown in a cool greenhouse.

B. arundinacea.—An Indian species distributed widely on the plains and low hills, also found in Ceylon. Height, 80–100 ft., with a diameter of 6 ins. or more. An important species from an economic standpoint but too tender for outdoor culture here. Plant in a warm greenhouse or large stove; it is too vigorous for any but the largest structures. It is peculiar by reason of its very spiny stems.

B. polymorpha.—This tall-growing species attains a height of 80 ft., with stems up to 6 ins. in thickness. A native of India, it can only be grown in warm houses here.

B. Tulda, a vigorous species 30–70 ft. high, native of India, is of little horticultural value as it can only be grown in large houses. Its stems can be used for building purposes, paper, etc.

Cephalostachyum.—*C. flavescens.*—This Burmese Bamboo is an elegant habited species 15–20 ft. high, with stems up to 1½ in. in diameter. It is a graceful plant suitable for a warm greenhouse.

Dendrocalamus.—*D. giganteus* is one of the largest growing Bamboos, attaining a height of 100 ft., with stems up to 10 ins. in diameter. Native of the Malay Peninsula, etc., and cultivated in India, it is an important species from an economic point of view. Its large size is against it for indoor cultivation, although it is sometimes included in lofty palm houses, as at Kew.

D. sikkimensis is another large-growing species, for it exceeds 50 ft. in height, with stems up to 7 ins. in diameter. It is curious by reason of its purplish, intensely hairy culm-sheaths. A native of Northern India. It requires a warm greenhouse.

D. strictus, 20–50 ft. high, with stems 2–3 ins. in diameter, is widely distributed in India. It is a handsome plant suitable for a warm greenhouse.

Gigantochloa.—*G. verticillata.*—This is a large-growing species from the Malay Peninsula. It is met with 80–100 ft. high, with stems 5 ins. in diameter. Its stems are of value for building purposes, etc. It can only be grown here in a warm glass structure.

Oxytenanthera.—*O. abyssinica* is a tropical African species at least 50 ft. high, with stems 3 ins. in diameter. The leaves are up to 10 ins. long and 3 ins. wide. Plant in a tropical house.

Phyllostachys.—*P. aurea,* a native

of Japan, has yellowish stems 12–15 ft. high. It is of erect habit and distinguished by the crowded nodes near the base of the stem. Hardy.

P. Castillonis, from Japan, may exceed 12 ft. in height. It has golden stems, with the exception of the flat portion between the nodes, which is bright green. The leaves are sometimes variegated. Hardy.

P. flexuosa, native of China, is a handsome plant of elegant growth, with stems 8–10 ft. high.

P. Henonis is another very beautiful plant of graceful outline, growing 10–12 ft. high. Native of Japan. Hardy.

P. mitis is not very hardy, but in mild districts it sends up erect growths to a height of 20 ft. Native of Japan.

P. nigra, growing up to 20 ft. high, is a handsome and useful species from Japan. It is distinguished by its black stems. In the variety *punctata* the stems are mottled. Hardy.

P. Quilioi grows 12–18 ft. high and bears handsome foliage larger than that of other species of Phyllostachys. Native of Japan. Hardy.

P. ruscifolia, a dwarf species from Japan, grows about 2 ft. high, and has no special value. Hardy.

P. viridi-glaucescens is perhaps the best-known species of the genus, for it was introduced from China about the middle of last century. Growing 12–18 ft. high, it forms very large clumps with graceful arching branches. Hardy.

Thyrsostachys.—*T. siamensis* is a strong plant with stems 20–30 ft. high and up to 3 ins. in diameter, from Siam. It is of no value here, for it can only be grown in a tropical house, but it has an economic importance in Siam.—W. D.

BAMBUSA.—A species of Bamboo. See *BAMBOOS.*

BANEBERRY.—See *ACTAEA.*

BANFFYA.—Now included in the genus *GYPSOPHILA.*

BANKS' PINE (*Pinus banksiana*).—See *TREES.*

BANKS.

These are usually necessary to support higher ground in the garden, and are preferable to walls inasmuch as they can be made far more beautiful. There are various kinds of banks, on some of the more important of which we enlarge below :—

Grass Banks.—These are the most unsatisfactory of all banks, inasmuch as they are very rarely tidy and hardly ever look well. The grass has to be kept short, and this is not easy even with a scythe, since, if the banks are at all steep, it is impossible to use the tool. For the same reason it is impossible to use the mowing machine. Grass banks are fortunately less common than they were ten years ago ; it is time they gave place to something more beautiful.

Rock Banks.—Rocks of varying sizes may be used with great effect for the holding up of soil to form banks, and these are about the most satisfactory kind of bank there is. Herbaceous plants, rock plants, and most of the hardier subjects described in our article on *CLIMBING AND TRAILING PLANTS*, may be effectively used for clothing them, and where the choicer alpines are used, some rocky steps should be arranged at intervals so that it is easy to get to them for the purpose of watering.

Rose Banks.—Where turf banks exist it would be much better either to remove the grass altogether or to take out holes in it, and in both cases to plant rambler roses on it.

Such sorts as *Crimson Rambler, Dorothy Perkins, Minnehaha,* and *White Dorothy* simply revel in such sites if the soil is made reasonably rich. Very little pruning is necessary, and the more the roses are allowed to have their own way the more lovely they look.

Shrub Banks.—These are far too abundant and cannot be recommended, since none of the choicer shrubs look really happy on them, with the exception, perhaps, of the stronger Rhododendrons on very slightly sloping banks. The coarser Laurels and so on will thrive well enough, but are apt to become leggy and ugly, while Azaleas and the choicer Rhododendrons, though often used for clothing such banks, seldom do as well as they would in shrub borders. The average shrub bank is as unspeakably ugly as a rose bank is unspeakably lovely.

Wild Banks.—These are often necessary and look well in the wild garden. In the winter they are beautiful with woodland-loving bulbs, and in the summer wild annual flowers are usually grown on them. Wild banks often lead down to lakes or ponds for the wild garden, and should never be far removed from the water garden. A combination of wild gardening and shrub gardening on a gentle slope leading down to a lake has great possibilities, and if flowering shrubs are freely used some wonderful colour pictures may result.—E.

BANKSIAN ROSES. — See *ROSE CLASSES.*

BAPTISIA (Nat. Ord. Leguminosæ). About half a dozen sorts of this may be recognised as species, though over a dozen have been described as such. All are hardy herbaceous perennials of very easy culture, thriving in ordinary garden loam in a sunny or very lightly shaded spot. They may be propagated by division of the roots in the usual way from November onwards, and the best planting period is March. The two best sorts to grow are :—

Baptisia australis.—A blue June flowering sort growing about a yard high.

B. tinctoria (WILD INDIGO).—A yellow July flowering sort growing half a yard high.

BASKET PLANTS.

The cultivation of various kinds of plants in hanging baskets is desirable from an æsthetic standpoint and also from the fact that certain species respond more kindly to that method of culture than to any other. In the first place basket plants add considerably to the appearance of greenhouse, conservatory, or corridor by breaking up the vacant head-space, whilst well-chosen subjects are seen to greater advantage than they would be were they grown in any other way. Secondly, the compost in which the plants are growing is always well aerated and there is less chance of its becoming sour or otherwise unsuitable for the maintenance of plant life than when it is enclosed in pots or forms borders. This alone is a great consideration in the care of certain species that are difficult to grow, and the large number of Orchids requiring basket treatment may be cited as belonging to this class. With Orchids, however, we have nothing to do in this article but rather to subjects that are available for more general use.

Baskets made of galvanised wire or wood are most frequently used, the former being the more serviceable. In some instances wire baskets are manufactured for ornament rather than plant cultivation, and it is wiser that the grower should select those of simple make, the ordinary plain round one being most serviceable. Care must be taken to ascertain that they are strongly made, for faulty construction may lead afterwards to the destruction of a finely-grown plant. When wooden baskets are used they should be made of teak, for that wood stands the damp conditions better almost than any other.

When preparing the baskets for the accommodation of plants they should be lined with moss, good fibrous loam or peat. Loam or peat, according to the plants to be grown, are preferable to moss. Good pieces, at least 3–4 ins. across, should be placed round the wires, then the remaining space filled in with a suitable compost. A tidy finish is ensured by rubbing the outside round with the hands and clipping off any long fibres. It is better to use young vigorous plants for baskets than to select well-grown subjects, for they are more easily manipulated and trained into the desired formation. Further, if basket plants are beginning to deteriorate, it is better to destroy them and commence again with young stock rather than to try to doctor them. It is rarely possible to remove plants from baskets and place them in larger ones, and if it is thought desirable to give more root room the best plan is to place the old basket inside the new one and fill in the vacant space with new soil. Vigorous plants can, however, be kept in excellent condition for a considerable period by weekly application of manure water or some chemical manure. When baskets are first filled with plants they should be kept in a warmer structure, until growth is active, than is required later on.

The Best Basket Plants.—In the following notes attention is directed to some of the most suitable plants for baskets:—

FUCHSIAS are charming basket

plants, and they are available for everyone, in addition to being suitable for greenhouses, conservatories, and for porches, summer-houses, etc. Varieties of free, spreading habit should be chosen, and one to three plants 5–6 ins. high placed in a basket 15–18 ins. across. If the baskets are filled in March, excellent specimens can be produced by the end of May which will blossom throughout the summer. A few good varieties for the purpose are—Avalanche, Charming, Daniel Lambert, Elizabeth Marshall, Loveliness, Rose of Castile.

SHRUBBY BEGONIAS with trailing branches form good basket plants. These should be pegged round the sides of the basket as they elongate, and some shoots may be trained up the supporting wires. The best of all is *B. glaucophylla*, a handsome plant with reddish flowers. Others with erect branches such as *B. gracilis*, *B. kewensis*, and *B. coccinea* can also be used, whilst *B.* "*Gloire de Lorraine*" never looks better than when growing in a hanging basket.

ASPARAGUS SPRENGERI forms a well-furnished basket of greenery, its long plumose shoots hanging from the basket to a depth of 2–3 ft. During the autumn and winter the green leaves are often relieved by red berries. Other notable and useful species are *A. crispus*, *A. scandens*, and *A. verticillatus*.

FERNS are popular basket plants for moist greenhouses and stoves. Most of the Adiantums or Maidenhair ferns are available as also are the finer growing Hare's-foot ferns (Davallias), such as *D. canariensis*, *D. elegans*, and *D. repens*. The following are also useful: *Asplenium bulbiferum*, *Gymnogramme elegantissima*, *G. schizophylla* and variety *gloriosa*, *Hypolepis distans*, *Nephrolepis cordifolia*, *N. exaltata*, the various Stag's-horn ferns, particularly *Platycerium alcicorne* and *P. æthiopicum*, etc.

Although not usually grown in baskets, the various ACHIMENES give excellent results as basket plants. When filling the baskets the corms should be so placed that they will grow from the sides and bottom of the basket as well as from the top. *A. coccinea*, *A. grandiflora*, and *A. Verschaffeltii* are specially worthy of note.

LACHENALIAS can also be successfully grown in baskets, the bulbs being placed in the same manner as described for Achimenes. The Rat-tail Cactus (*Cereus flagelliformis*) forms an excellent basket plant for a sunny greenhouse or window. It ought not, however, to be given a very large basket.

Another member of the Cactus family suitable for baskets is *Epiphyllum truncatum*; this thrives best in a rather moist and warm house. The various varieties of Phyllocactus can also be used.

An out-of-the-way plant for a sunny greenhouse is Sturt's Desert Pea (*Clianthus Dampieri*). Most people who have seen this gorgeous plant in flower try to grow it and usually fail. If, however, they sow seeds of *Colutea arborescens* singly in thumb pots a fortnight in advance of seeds of the Clianthus, then as soon as the Clianthus seedlings appear, and before they form their first true leaves, graft them upon the Colutea stocks, they will have every chance of success. It forms a very beautiful basket plant.

Hardy plants such as Ivy, *Lonicera japonica variegata*, and *Vinca minor* can all be requisitioned for outdoor baskets if desired. Ivy-leaved geraniums are excellent subjects for outdoor work in summer. Young plants placed in baskets in March or early April, and kept in-

doors until early June, produce well-furnished specimens which remain in bloom all summer. In some instances several species of plants are placed in the same basket, but as a rule single examples are the more effective. In addition to the plants mentioned many others will suggest themselves to those who are interested in the subject.

BEAN RUST.—See *DISEASES OF PLANTS*.

BEANS (Nat. Ord. Leguminosæ). Of these there are many sorts, The following notes deal with all those usually cultivated :

Broad Beans (*Vicia Faba*).—These are one of the most accommodating crops, thriving well in almost every district and upon any soil. However, a little extra attention in the way of manure or deep digging generally increases the size of the bean and number of the pods.

On very light soils sowings may be made from November to the end of May, but where this is of a wet nature, sowing is not advised before March. Sow in double rows 5 ft. apart, allowing 6 ins. between the plants in the rows, and cover the seed with not more than 2 ins. of soil. Spinach and turnips may be grown between the rows. If either are sown, it is important these should be withdrawn as soon as of usable size.

A plan finding much favour among those having a heated greenhouse is to sow the seed 3 ins. apart in shallow boxes early in the year, removing these to a cold frame when the plants are 3 ins. high, planting into open quarters about the end of March. The earliest crop must be well earthed when 6 ins. high. Nip the tops out of the plants as soon as the bloom is fairly set, to serve the double purpose of destroying numerous insects and hastening the development of the pods.

GOOD VARIETIES include Bunyard's Exhibition, Exhibition Long Pod, Giant Windsor, Hartington Long Pod, Improved Windsor, Kinver Monarch, Knight's Tremendous, and Leviathan.—F. R. C.

Climbing French Beans (*Phaseolus vulgaris*).—These are distinct from the ordinary Dwarf French Bean. They are very heavy croppers, but need less support than the ordinary Runner Bean, otherwise the treatment is similar. In this section there are several varieties of tall-

growing Butter Beans, all of which are worth attention. *Princess of Wales* and *Tender and True* are among the best French Climbing.

Dutch Brown Beans (*Phaseolus vulgaris*).—These came much to the front during the recent terrible European War. Analysis shows that they are much richer in true food (protein) than beef, and they also contain a large quantity of valuable carbohydrates which are totally absent in beef. They found much favour when tried at the Wisley Gardens, and seed was distributed to Fellows, by the Royal Horticultural Society, during the spring of 1918. The Society warns growers not to eat the pods, as is done in the case of Dwarf French, or Runner Beans, but to allow the seeds to ripen, shell them, dry them, and use them for winter food, as to eat the young pods is very wasteful.

CULTURE.—A rich soil is necessary for the successful culture of these Beans, the seed of which should be sown about 15th May, or later still if the district be cold and exposed. Each seed should be set 1 ft. from the next, and each double drill should be 2 ft. from its neighbour. They should on no account be planted with a dibber. Frequent hoeing, feeding, and watering are advisable.—EDITOR.

Dwarf Beans (*Phaseolus vulgaris*).—With good cultivation these form one of the most useful among summer crops. The reason why this fact is not more fully recognised is due to the prevailing error of sowing only in poor ground, and failing to allow sufficient space between the plants. A good open spot should always be selected and a good dressing of half-decayed manure given. Then you start on the high road to success.

CULTURE.—From 18 ins. to 20 ins. should be the minimum space between rows, and each plant allowed a clear foot from its neighbour. Seed sown more closely in a wet season often encourages rotting off; any surplus not required may be transplanted to other quarters and invariably provides a useful "follow on" to the original row.

The plants need abundance of water, especially after the first pods commence to swell. Where water is scarce and the soil light a mulch of some kind should be placed over the roots as soon as flowers show. For this purpose old hotbed manure, tan, or leaf-soil answers very well.

Gather all pods as soon as they are fit for cooking, even if these have to be given away. By so doing the productive power of the plant is maintained, but should even a few pods reach the ripening stage no further pods need be expected to form.

GOOD VARIETIES.—Canadian Wonder, Everbearing, Magnum Bonum, Osborne's Forcing, Perfection, Plentiful, and Reliance are as good as any.

The **Dwarf Wax-pod**, or **Butter Bean** (*Phaseolus vulgaris*), is worthy of extensive cultivation, coming to maturity earlier in the season than others in this section, the beautiful golden pods being very freely produced. These pods are best if cooked whole, and are of very delicate flavour.

Sow from the end of April until the first week in July, or, for very early picking, sow under glass the first week in April, and plant out six weeks later in a sheltered spot, protecting from cutting winds. [In very cold exposed districts sowing out of doors is not recommended before early June.—ED.]

Runner Beans (*Phaseolus multiflorus*).—During recent years a great advance has been made in this section; and certainly no popular

vegetable of to-day better repays good cultivation than a first-class variety of these; the number and length of the pods produced by a hundred good healthy plants being almost incredible to those who know only the older varieties.

CULTURE.—Plenty of good fat manure for the roots to feed upon, ample room for the large leaves to develop, together with unstinted supplies of soft, or rain water, sum up the secrets of successful culture.

Start early in the spring by choosing a site in the open garden, right away from trees of all kinds. This should be thoroughly trenched or double-dug, well mixing plenty of nearly fresh manure with the bottom spit of soil. For a row the width of the ground should be a full yard.

Seed for the earliest crop should be sown from the middle to the end of April; for later crops until mid-June. [In very cold exposed districts seed should not be sown out of doors before the third week in May.—ED.]

Upon the ground previously trenched, draw out a drill not less than 6 ins. deep, and 15 ins. wide, treading the soil moderately firm. Sow the seed in a double row, allowing 10–15 ins. between each seed, always putting in a few extra at each end of the row for later transplanting should any of the others fail to germinate. Cover with about 3 ins. of soil.

Before the plants commence to run, give each a good stout stick or pole 8–10 ft. long, and instead of inserting this quite close to the plant, and thus damaging the young roots, put it midway between the plants in a perfectly upright position, tying the sticks in opposite rows together, a few inches from the top, or, better still, have a good stout and perfectly straight stick tied horizontally at nearly the top of the poles to which these may be tied, thus ensuring greater neatness and stability.

As already pointed out, moisture is of the greatest importance, it being almost impossible to overwater a well-prepared row; but very hard water, or water from a deep well, should be exposed to sun and air for several hours before using, it being possible to kill outright the most healthy plants by using such water too freely.

Syringing overhead each evening after a hot day is most beneficial, especially when the flowering stage is reached, and syringing two or three times a day will hasten the setting, also the development of the pods. Liquid manure should be given after the first pods are 6 ins. long, or equally good results will follow the use of fish manure, sprinkled along each side of the row at the rate of 2 oz. to the lineal yard. This last should be lightly pricked into the soil with a fork, and afterwards well washed in.

FOR EXHIBITION.—If extra large pods are desired allow each plant to carry but a single shoot; single rows of plants would also be preferable. From these plants all side growths or laterals should be removed, and as soon as the best shaped pods can be discovered, select not more than two from each truss.

Where the soil is very light, liquid manure may be given twice a week from the time the pods are a few inches long until the end of September. On heavy soils once a a week will be ample, but no matter what may be the nature of the soil, a light mulch of rich manure applied along each side of the row early in August will be an advantage. Gather all pods before they become too stringy for the table; the re-

tention of such upon the plants prevents the development of others.

GOOD VARIETIES for large pods include Emperor, Exhibition, Hackwood Park Success, Mammoth Scarlet, and Mammoth White, Prizewinner, Sutton's A1, and Sutton's Best of All.

Stringless Beans (Tall). — These are not very popular among vegetable growers, but are well worthy a place in gardens where a great variety of vegetables is valued. If treated liberally in the matter of manure and moisture the cropping powers are extraordinary, the long pods hanging in great clusters. Not being of such robust growth as the ordinary Runner Bean, the sticks usually used for tall peas answer well for these. The pods are stringless and if preferred may be cooked whole. Sow the seed early in May, a distance of 6–9 ins. apart in the row being ample.—F. R. C.

NEW VARIETIES.

The following are some of the best :—

BROAD :—*Sutton's Unrivalled.*—This is of the Windsor type, but with large pods of green seeds. It is a free bearer, of robust habit.

DWARF : — *Feltham Prolific.* — This has medium-sized, rich green, fleshy, almost stringless pods. It is a heavy cropper, of very dwarf habit.

Longpod Wonder. — This bears long, pale, straw-coloured, stringless pods in clusters. It is a heavy cropper, excellent for forcing or early work, coming in three weeks earlier than the old *Canadian Wonder.*

Sutton's Satisfaction.—This has long, very tender pods, which are stringless when young. It is an exceptionally prolific sort, and a quick grower, equally good for forcing or for the open ground.

White Leviathan.—This is a white-seeded *Canadian Wonder* variety, of vigorous growth, and a heavy cropper. The beans may be ripened for use as haricots.

RUNNER :—*Sir Douglas Haig.*—A strain of Scarlet Runners with very broad and stout pods. The quality is excellent, and the variety is exceedingly prolific.—W. J. C.

BEDDING OUT, PRACTICAL HINTS ON.

There are many hundreds more failures in Bedding Out than there should be, and these failures result from lack of attention to small practical details more than anything else. In this article we propose to deal with the practical side of the question, leaving another contributor to deal with the subject of *BEDDING SCHEMES FOR SUMMER AND WINTER.*

Our first consideration in Bedding Out must be the

Preparation of the Site.—It seems to us that very few gardeners realise what hungry subjects Wallflowers

and other winter bedding plants are, or they would not put summer plants in their positions without well manuring the beds first. This mistake is most often made: it is the rarest thing for summer beds to be thoroughly manured prior to the planting. Winter bedding plants will not need a lot of additional food if planted in October in beds which have been previously well manured for summer bedding plants, but more often than not the question of manuring beds at all, whether for summer or winter plants, is waved aside and the plants are put in soil which grows yearly poorer.

Poor soil for summer bedding plants is a very serious matter, in fact it may mean total failure. Rich soil, on the other hand, is one of the high roads to success, and should always be available.

Of the manures to use, the two we prefer are very old cow manure, and old hotbed manure. The cow manure is preferable for a light soil. The manure should be dug in immediately the old bedding is off the land, and should be buried about 10–12 ins. down.

Hardening the Plants.—Probably the greatest fault of all in summer bedding is to omit to harden the plants completely before setting them out in their new positions. We should think this mistake obvious, and its prevention equally obvious, but this is not the case. We constantly see boxes of plants transferred direct from frames, which have been kept closed and warm for many weeks, to borders during cold weather, and plants so treated cannot avoid being greatly checked. Hardening off is more fully dealt with in a separate short article on the subject, so all we need do now is to insist on the wisdom of gradually inuring the plants more and more to being in the open air for many weeks prior to planting out.

Dry Weather Planting.—It often happens that in late May or early June when the summer bedding plants have to be put out, the soil is very dry, and the same thing frequently occurs when the winter bedding is put down in October, if the month of September has been nearly rainless. Dry weather planting is never a great success, and it may be a complete failure. In any case precautions should be taken. Both the new sites and the present sites of the plants should be very freely watered the night before re-planting, since it is only thus that the work can be safely done. It is no good thinking that a drop of water is enough for the purpose: it is not: what is wanted in both cases is a thorough good soaking.

Mistakes in Planting.—It is not often that care is taken of the bedding plants when they are being lifted from nursery beds outside, from boxes in frames, or knocked out of pots. Gardeners frequently drag the plants up anyhow, or roughly knock them out of the pots tearing the crocks away with no regard at all to the tender roots of the plants. These are terrible mistakes. The plants should be most carefully lifted with a small handfork with as large a ball of soil on their roots as possible, or in the case of the pot-plants they should be turned out of their pots with some care, the crocks being removed so gently that no roots are injured at all and the soil ball remains unbroken.

Further mistakes are to attempt to plant with a wide dibber, and to plant so loosely that the plants can most easily be pulled out of the ground.

The former mistake is almost too foolish to comment upon, since it should be obvious that no plant can

thrive if it is cramped into a hole far too small for it, and at the same time finds a cavity of air immediately under the ball of soil for its roots to run in. Obviously a hole should be taken out with a trowel or with the hand, which is amply large enough to hold the ball of soil and roots without any cramping. Care should be taken not to bury the plant deeper than it was originally, or it may damp off. The matter of loose planting deserves a special word of comment. Gardeners as a whole utterly fail to see the necessity for firm planting; otherwise we should never see a single one out of the hundreds of cases we do see of plants "falling over" immediately after being re-planted. Firm planting is essential if there is to be immediate new root action, and new root action is essential if the plant is to become established in its new position, hence firm planting is the high road to establishing bedding plants successfully. We certainly consider that the firmer the plants are made in the ground the quicker they become established; this has been proved by comparison with loosely set plants of the same genus.

Another mistake in planting is overcrowding. Gardeners wishing for immediate effect always seem to forget that the plants require room to grow during the next four months. Thus the appearance of the borders is soon utterly spoilt, and the plants completely ruined because too many have been put into one border. As a rule a distance of 6 ins. apart each way should be the absolute minimum for summer bedding, except when the plants are really exceptionally small. Where the plants are of fair size, 9 ins., or even as much as 12–14 ins., apart each way will be required.

Yet another mistake is to put plants with glaring, clashing colours side by side; but as this point is fully dealt with by other contributors, we do not propose to comment upon it here.

Watering after Planting.—In hot weather the bedding out should very preferably be done in the late afternoon or evening. Thus immediately it has been completed the plants can receive and should be given a thorough good soaking of warm water from a fine-rosed can. This will settle the soil about their roots and do more than anything else to establish them. Next morning very early it is advisable to syringe them lightly over, and the same evening another good watering can be given. It may be necessary to continue the daily watering and syringing for a week or more, after which it may be stopped and only done in very hot dry weather. Never water the plants in hot sunshine or they will be badly burnt. Even in very wet weather some of the borders will need watering if they have been protected by the dwelling-house from the driving rain.

Feeding.—Certainly bedding plants are much neglected in the matter of feeding, but no class of plants repay it better. Weak liquid manure applied once a week has a truly wonderful effect on their growth and flower-productiveness, and this fact should be appreciated by gardeners. Phosphate of potash or ammonia, sulphate of iron, and superphosphate of lime, so long as given at about half the usual strength, have a wonderful effect, and so also has very weak liquid animal food. Both should be kept off the foliage.

Small Matters.—Early attention should be paid to the clipping of the grass verges of the bedded-out borders, for nothing detracts so much from their appearance as

does a shaggy beard. Attention should also be given to removing dead flowers, to training the trailing varieties of plants down in the way they should go, and so on. When a plant fails, take it out and set something else in its place. When plants make long undesirable shoots without flowers, cut these shoots out and use them if need be for propagating purposes. Keep all bedded-out borders weeded, for flowering weeds detract greatly from the appearance, and are apt to disgrace the gardener in the eyes of his friends. In the cases of both winter and summer bedding, be "in time" with regard to the plants. Baby seedlings are no possible value; they will not flower for many months, and this lateness is wasted time. Sow them early enough; then the plants will be on the large, rather than the small, side. This inevitably means earlier, larger, and better flowers, so it is worth taking a little trouble in this direction. With winter bedding do not wait until the bad winter weather sets in during November. Put your plants in place in October; then they will have a good chance to get established before the bad times start.—E.

BEDDING PANSIES.—See *PANSIES: CULTURE OF.*

BEDDING PLANTS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING.*

BEDDING PLANTS, CULTIVATION OF. A glance down the list of summer bedding plants will show what great variety there is both in type and hardiness of the plants. For instance, next to each other we have the hardy annual Calendula and the half-hardy perennial shrubby Calceolaria. We could write at great length on the cultivation of bedding plants, but owing to space limitations we must refrain from entering into all unnecessary details and give a few really practical hints instead.

The Start.—As a general rule a start is made by sowing all the half-hardy or tender annuals and perennials in boxes in heated pits, frames, or glasshouses, during January or early the following month. It is a usual maxim that the smaller the seed, the finer the seed-bed and the lighter the soil covering of the seed must be. Very small seed should be mixed with ten times its own amount of fine silver sand. Extra choice, very small seed should be sown on the surface of pans or boxes after covering the soil completely with a thin layer of silver sand. The seed after sowing is then lightly covered with more sand.

The greatest care must be taken in sowing to sow extremely thinly to allow room for growth before pricking out commences. After sowing, the pans or boxes should be immersed to within an inch of their rims in a trough of warm water, the water being allowed to soak through. When this has taken place, the pans, etc., are covered with slates to keep them dark until the seed germinates.

A suitable compost for sowing and pricking off seedling bedding plants is made by mixing equal parts old loam and old leaf-soil with as much as ¼ part of sharp silver sand, and a generous dash of wood ashes, old soot, and bone-meal.

Pricking Off.—The early stages of the plants are the most important of all, for on them depends success or failure in the future. You will never get a long lanky seedling Schizanthus to give you a good bunch of bloom, nor will small sturdy "stumpy" seedlings give

poor bad flowers. From the first moment the seed starts germinating, care should commence. All possible excess of moisture must be avoided or damp will set in. The plants must be brought gradually to the light, and after that given all the light and air possible, otherwise they soon turn spindly. Early pricking out should be done, the plants being set 3–4 ins. apart each way very firmly in large rectangular boxes. These after being watered are shaded for a few days and then put on the shelf close to the glass and given further doses of light and air. Early in May transfer the lot to cold frames and harden off. (See short article on *Hardening Off*.)

Hardy Annuals.—When these are used as bedding plants they should be sown in early March in pans or boxes of prepared soil, and the same efforts made as described above to induce them to make short sturdy growth. They are pricked off into other boxes in April, and planted out during the following month. They may also be sown in the reserve garden, pricked off there, and re-planted into their permanent "bedded-out" positions.

Hardy Biennials. — These are mostly used, when used for bedding at all, in winter or spring work. They are for this purpose sown in open sunny reserve garden beds, or sown in a frame, in June or July, pricked off into nursery beds 6 ins. apart from plant to plant, and transferred to their permanent quarters in manured land during October. Firm planting is essential to success.

Hardy Perennials. — These when used for summer bedding and raised from seed are treated almost exactly the same as are half-hardy annuals, being sown in January or February, pricked off in March or April, hardened off, and planted out in May or June. When used for winter bedding, sow in June or July.

Greenhouse Plants.—These, when used for summer bedding, are encouraged to grow rapidly from February to May by giving them more heat than half-hardy annuals and plenty of moisture. They are then very gradually hardened off and planted out in June after all danger of frost is over.

Disposal of Bedding Plants. — When the summer is over and the autumn frosts commence, it is usual to pull up the summer bedding plants and destroy them. Where a supply of winter bloom is wanted in the greenhouse, however, this can often be obtained by lifting the best plants from the beds with care, and potting them on at once. When there are plenty of plants this need not be done, and certainly it should not be bothered with in the case of any of the commoner flowers. Care should be taken to see that a sufficient supply is kept for next year's possible needs. These are boxed up close together and put into a cool greenhouse, water being withheld except when absolutely needed.

Cuttings of Bedding Plants. — Undoubtedly the best months to take these are July and August. Then they can with the greatest ease be struck by inserting them in a slightly shaded bed of sandy soil, or in the case of Geraniums in a sandy bed in full sunshine. Moisture at the root and occasionally overhead will soon induce the formation of roots. Gardeners should realise that an enormous number of half-hardy bedding plants can be propagated in this way. Some men consider that a frame is absolutely essential; so it is if the propagation is not started until cool September sets in, but during July and August it is not in the

least necessary, except in the case of a very few "shy" plants. Far better to reserve a stock of rooted cuttings of bedding plants at a safe period, rather than wait for an unsafe period and then depend on all the cuttings rooting. Usually if the plants have been properly managed, there is no lack of young succulent growth ideal for cuttings during July and August, so they should unhesitatingly be taken. It is only necessary finally to reiterate here that all summer bedding plants intended for next season should be out of the open garden and under suitable cover in heated structures by September 30th, since a sudden frost may otherwise kill the lot. Also all winter or spring bedding plants should be in place by the end of October to give them a good start before the winter.—E.

BEDDING PLANTS, CUTTINGS OF.—See CUTTINGS OF BEDDING PLANTS in *BEDDING PLANTS: CULTIVATION OF.*

BEDDING PLANTS, SELECTED LISTS OF.—The following are specially selected lists of some of the best plants for use in bedding.

SUMMER BEDDING PLANTS.

Agathæa cœlestis.
Ageratum Blue Perfection, Little Dorrit, etc.
Alonsoa Warscewiczii.
Alyssum Lilac Queen, maritimum, minimum.
Amarantus tricolor.
Anagallis grandiflora.
Antirrhinum Dobbie's Brilliant, Primrose King, Amber Queen, Carmine Queen, Cottage Maid, Nelrose, Queen of the North, Tom Thumb (many colours).
Arctotis grandis.
Asters, Comet, China, Chrysanthemum-flowered, Paeony-flowered, Quilled, Dwarf Victoria, etc. etc., varieties and colours too numerous to mention.
Balsam, Ryder's Prize, The King, The Queen, Dobbie's Selected, Ryder's Dwarf Bedding.
Bartonia aurea.
Begonia Dobbie's Selected Single, and Blackmore's Double.
Beta Chiliensis.
Brachycome iberidifolia Blue Star, and White Star.
Browallia grandiflora.
Calceolaria Dobbie's Perfection, Ryder's Superb, etc.
Calendula Dobbie's Orange, Meteor, Prince of Orange, Favourite, etc. All splendid plants.
Calliopsis Crimson King, Drummondii.
Candytuft White Spiral, Rose Queen, White Rocket, Little Prince.
Cannas, any Crozy varieties.
Celosia pyramidalis Thompsoni.
Centaurea candidissima and Cyanus, especially dwarf Cyanus.
Cerastium arvense, tomentosum.
Chrysanthemum coronarium, inodorum, tricolor, Lord Beaconsfield, Morning Star and Northern Star.
Cineraria maritima.
Clintonia pulchella.
Coleus Verschaffeltii.
Convolvulus minor coeruleus.
Cosmos Crimson King, Rose Queen.
Cuphea platycentra.
Dahlia Cactus, Collerette, Fancy, Paeony-flowered, Single Cactus, and Single sections. Hosts of named varieties. Unless dwarf Star Dahlias are used the above sections will have to be put at the back of the borders.
Delphinium Azure Fairy, Blue Butterfly, Cardiopetalum, chinense, and formosum.
Dianthus chinensis, Heddiwegii, and laciniatus.
Diascia Barberae.
Dimorphotheca aurantiaca hybrida (Golden Star of the Velde).
Echeveria, all varieties.
Eschscholzia crocea, Douglasii, and Mandarin.
Fuchsia (for specimens), any good greenhouse variety.
Gaillardia amblyodon, picta Lorenziana, etc.
Gaura Lindheimeri.
Geranium (Zonal Pelargonium), Happy Thought, Henry Jacobey, Mrs Pollock, Paul Crampell, etc. etc.
Gerbera Jamesoni (Barberton Daisy).
Godetia Bijou, Duchess of Albany, Gloriosa, Lady Albemarle, Lord Roberts, Rosamund, Schamini, White Pearl, Whitneyi, etc. etc.
Golden Feather (*Pyrethrum aureum*).
Helichrysum monstrosum, nanum, setosum (various beautifully attractive colours).

Heliotropium peruvianum, Regale Margaritæ.
Herniaria hirsuta.
Ice Plant (*Mesembryanthemum*).
Jacobaea (*Senecio elegans*), Double Crimson and Double Purple.
Lantana hybrida.
Larkspur Hyacinth and Ranunculus-flowered.
Leptosyne maritima, Stillmannii.
Lobelia cardinalis, Erinus vars, erecta pumila splendens, hybrida, tenuior, etc. Many named sorts.
Lupinus nanus and subcarnosus.
Marigold, African, French, named varieties.
Marvel of Peru (*Mirabilis*).
Matricaria eximia Golden Ball, and Silver Ball.
Melianthus major.
Mesembryanthemum tricolor.
Mignonette (all varieties).
Mimulus cupreus, cardinalis, albus, tigrinus, etc.
Nasturtium Tom Thumb, Aurora, King of Tom Thumbs, King Theodore, Ruby King, Golden King, H. M. Stanley, etc.
Nemesia Blue Gem, Dobbie's Triumph, and strumosa Suttonii.
Nicotiana affinis and Sanderæ.
Nierembergia frutescens and gracilis.
Nigella damascena, and hispanica atropurpurea.
Œnothera bistorta, macrocarpa, and mexicana.
Pansy, all Bedding Strains, such as Fairy Queen, etc.
Pentstemon, every variety.
Perilla nankinensis.
Petunia Dobbie's Superb Double and many others.
Phlox Drummondii grandiflora and compacta in separate colours (many sorts).
Portulaca grandiflora, single and double.
Prince's Feather (*Amarantus hypochondriacus*).
Pyrethrum aureum (Golden Feather), selaginoides.
Rhodanthe maculatum, Manglesii.
Salpiglossis grandiflora.
Salvia coccinea splendens, farinacea, patens, splendens, Pride of Zurich.
Saponaria calabrica rosea.
Scabious atropurpurea, aurantiaca, minor aurea, and sulphurea.
Schizanthus grandiflorus, pinnatus, retusus, Wisetonensis, etc.
Senecio (under Jacobaea).
Silene pendula compacta, and Fortunei.
Statice Bonduelli.
Stock East Lothian, Dwarf Bedding, Intermediate, Mammoth Ten Week, Perpetual-flowering, Pyramidal, and Large-flowered sections. Many named varieties.
Sunflower Dwarf Miniature.
Sweet Sultan (*Centaurea moschata* and *suaveolens*).
Tagetes signata pumila.
Torenia Baillonii, and Fournieri.
Trachelium caeruleum and c. album.
Verbena Defiance, erinoides, erecta compacta, Helen Willmott, lemon-scented, venosa (hybrid forms very beautiful).
Viola Maggie Mott, J. B. Riding, Mauve Queen, Fred Wilkins, and many others.
Zinnia elegans, single and double.

SPRING OR WINTER BEDDING PLANTS.

Adonis vernalis.
Alyssum saxatile compactum.
Arabis albida or alpina flora plena.
Aubrietia deltoidea Dr Mules, etc.
Bulbs, all spring flowering genera.
Canterbury Bells, Calycanthema, double and single.
Cerastium Biebersteinii.
Daisies Double (*Bellis perennis*).
Helleborus niger (Christmas Rose).
Myosotis alpestris, etc.
Polyanthus Munstead variety, etc.
Stock, Brompton varieties.
Sweet William, Auricula Eyed, Pink Beauty, etc.
Viola cornuta atropurpurea, named varieties.
Wallflower, single and double. Numerous beautiful sorts.—E.

BEDDING, ROSES FOR.—See ROSES FOR BEDDING in *ROSES FOR ALL PURPOSES*.

BEDDING SCHEMES : FOR SUMMER AND WINTER.—Experienced gardeners are quite able to plan their own bedding schemes, but amateurs and beginners often find considerable difficulty in planning out schemes of floral beauty, hence the suggestions which are given below.

Summer Schemes.—One of the prettiest beds that we have ever seen consisted of *Centaurea candidissima* and *Geranium Mrs Quilter*. This last plant has bronze and yellow foliage with pretty red flowers. As dot plants for this bed, hybrids of *Fuchsia triphylla*, such as *Andenken au H. Henkel*, may be used with

great effect, their pretty salmon-red flowers harmonising with the Geraniums. A double row of a light blue variety of Lobelia, such as *Blue Stone*, makes an effective edging.

Another useful bedding scheme is easily planned by using *Geranium Maxime Kovalesky* with pretty orange flowers. These plants are intermixed with *Chrysanthemum inordorum Snowball*. Dot plants of *Grevillea robusta* and an edging of *Alyssum Little Dorrit* complete a pleasing scheme.

A very bright bed will be obtained if crimson-scarlet tuberous Begonias of such variety as *Lafayette* are used with a groundwork of *Mesembryanthemum cordifolium variegatum*. A useful subject for dotting about in this bed is found in *Glyceria spectabilis*, which, although a water plant, grows well in beds. An edging of a blue Lobelia, such as *Mrs Clibran* or *Barnard's Perpetual*, will finish off this bed.

Another nice bed may be made as follows :—

First of all dot the bed over with any good dark flowered variety of Fuchsia such as *Charming*, then plant thinly with *Geranium Verona*, for its pleasing yellow foliage and pink flowers are most attractive, and finally make up the groundwork of *Viola Diana*, edging the bed with the crimson-flowered variety of *Begonia semperflorens*.

Another delightful bed may easily be made by planting the pink-flowered variety of *Begonia semperflorens* (*Fairy Queen*), in conjunction with the dark-leaved Cannas. *Centaurea candidissima* and *Geranium Mrs Quilter* may be used as a groundwork ; and as dot plants *Leucophyton Brownii* grown as pyramids will be useful. This bed may well be edged with the pretty *Geranium Dandy*.

A simpler bed may be made by planting *Geranium Paul Crampell* in conjunction with *Abutilon Thompsonii*, this bed being edged with *Alyssum Little Dorrit*.

Another satisfactory bed is easily made by planting scarlet tuberous Begonias and dotting plants of *Gnaphalium minimum* over the surface. A thick groundwork should be made of *Mesembryanthemum cordifolium variegatum*, and the border edged with a blue Lobelia such as *Crystal Palace Compacta*.

A bed with very distinct charm and somewhat unusual is made by intermixing *Salvia Bluebeard* with a yellow Calceolaria such as *Golden Gem* or *Golden Glory*. The bed may then be edged with *Viola Blue Bell*.

For a very large bed, a splendid lasting effect may be obtained by covering the ground thickly with a good yellow variety of *Tom Thumb Nasturtium* interspersed with dark-foliaged Cannas or *Zea japonica quadricolor perfecta*.

Winter Schemes.—For winter or spring bedding good effects may be obtained generally by the use of Hyacinths, Narcissi, Tulips, and other bulbs, with a carpeting of Double Daisies, or with the early flowering varieties of *Myosotis alpestris*, such as *Queen Victoria* or *Royal Blue*. Other splendid plants for spring bedding are found in the single, double, and variegated Arabis, Violas, Wallflowers, Polyanthus, and *Aubrietia deltoidea Dr Mules*. To lighten up the appearance of beds good use may be made of small shrubs such as Cupressus and Retinospora, as well as the green or variegated forms of Euonymus. If the shrubs are placed in pots there will be little danger of loss through taking them up, after they have fulfilled their purpose in the beds.

As regards particular beds the

following suggestions may be useful :—

Pink Tulips of any good variety, such as *Cottage Maid* or *Pink Beauty*, planted in a bed which is edged with light blue Violas, such as *John Quarton*, and a groundwork planted thereon of *Arabis albida flora plena*, is a pleasing combination.

Another useful bed is made up by planting yellow Tulips, such as *Chrysolora*, with a groundwork of *Aubrietia Dr Mules*, or an equally delightful bed may be made by planting scarlet tulips of such sorts as *Artus* or *Vermilion Brilliant* with a groundwork of single or double Arabis.

A further bulb bed may be made by planting *Hyacinth Charles Dickens* in a groundwork composed of a good yellow Polyanthus.

Narcissi are very useful for many spring bedding schemes. For instance, *Narcissus Emperor* interspersed with a dark Polyanthus, such as *Crimson King*, makes a most charming bed ; *Narcissus Golden Spur* with a carpeting of *Myosotis Royal Blue* is equally delightful, while *Narcissus Emperor*, or indeed any large trumpet sort interspersed with the Grape Hyacinth (*Muscari botryoides*), planted in a groundwork composed of *Arabis albida variegata*, makes an unusually charming and natural bed.

May-flowering and Darwin Tulips are useful for winter and spring bedding schemes. For instance, *Tulip Pride of Haarlem* planted amongst *Wallflower Cloth of Gold* is delightful, while *Tulip retroflexa* interspersed amongst *Wallflower Vulcan* makes a really grand sight. A very nice bed is obtained by planting the early flowering *Tulip Belle Alliance* intermixed with Jonquils, and with a carpeting composed of any good pale blue Viola such as *Blue Stone* or *Diana*.

It will be seen that the different combinations possible to obtain in the arrangement of plants used for bedding are almost inexhaustible ; obviously, however, of first importance is to have the plants well grown before they are put into their flowering quarters, and immediate effects should be aimed at since the seasons are much too short to have to wait long for results.—H. A.

BEDDING STOCKS.—See *Stocks*.

BEDDING VIOLAS.—See *Viola*.

BEDS : Shape and Character of. In the flower garden the most useful beds are either oblong or circular in shape, elaborate geometrical designs consisting of acute or obtuse angled figures being difficult to negotiate with the mowing machine, and except in very large gardens or in close proximity to the mansion where they can be made to enter into the architectural features of the building are quite out of favour with modern tastes. Oblong rectangular, or even square beds are permissible where they run parallel to a straight path, or when they are closely connected with the house or some other building such as a greenhouse, etc. Beds composed of gracefully curved or serpentine lines, alternating with circular or elliptical figures, are best suited to combine with paths or with portions of the lawn or garden having a similar outline. When arranging a scheme of beds preference should always be given to a simple design, selecting the position from the point of view of displaying the flowers to the best advantage, so that they can be seen from the principal windows, while, of course, considering the welfare of the plants by taking care to secure a position that is exposed to the sun, protected from the cold winds, and yet which gives a certain amount of privacy.

The soil for flower-beds should be deeply worked, liberally manured each time it is planted, trenched at least once in three years and well drained. The best flower-beds are made by taking the soil out to a depth of 2–3 ft., breaking the bottom up, and placing thereon 4–6 ins. of broken brick or other coarse material, finally filling up the bed with loam, or if the top spit should be of fair quality and texture, this may be mixed with sufficient new loam to make up the bed.

Beds are planted for both spring and summer effects. In the past bulbs have been largely used for spring effect, chiefly Crocuses, Hyacinths, Narcissi, and Tulips. These should be planted as soon as they come to hand, the beds having been well dug and manured after having been cleared of their summer occupants. The best effects are produced by first of all carpeting the beds with hardy plants, *e.g.* Arabis, Aubrietia, Myosotis, Polyanthus, also Double Daisies and Wallflowers; the latter, of course, being only suitable for carpeting the beds of some of the taller-growing Tulips.

The increased cost of bulbs is likely to restrict their use for bedding, and quite good effects may be produced by relying entirely on the hardy plants previously referred to. Their arrangement in the beds is a matter of taste, some preferring a colour scheme, others preferring a mixture. Wallflowers certainly look well when mixed, and good strains are available. Beds planted with these and edged with *Myosotis Royal Blue* or *Polyanthus Munstead Strain* leave nothing to be desired, and certainly look more natural and pleasing to the eye than splashes of each particular colour, or ribbon bands.

Summer bedding, that is, the summer planting of these beds, embraces Carpet Bedding, Sub-tropical Bedding, and Ordinary Summer Bedding.

Carpet Bedding.—This, years ago, was widely practised, and even now is of sufficient importance to warrant our publishing a special article upon it. Tastes differ, of course, as to its merits or otherwise, but it is clearly declining in popularity.

Sub-tropical Bedding.—This, to be effective, involves the use of many exotic species of plants, such as Palms in variety, Tree Ferns, Musas, Dracænas, etc., all of which require accommodation in heated greenhouses during the winter. The fuel question will rule out many of these subjects; so that this style of bedding will necessitate relying more on such subjects as *Bocconia cordata*, *Buphthalmum speciosum*, Funkia, Gunnera, Heracleum, Pampas Grass, Rheum, etc., while, from seed sown in the spring on hotbeds, Castor Oil Plants, Tobacco Plants, and Zea (Maize), as well as Beet, *Eucalyptus globulus*, Perilla, and some of the stronger-growing Solanums, may be made good use of.

Ordinary Summer Bedding.—This style is much more largely practised than any other. Some popular plants used for this purpose are Abutilon, Ageratum, Begonia, Celosia, Coleus, Fuchsia, Heliotrope, Lantana, Lobelia, Marguerite, Pelargonium, Plumbago, etc., all of which require to be wintered in heated structures, even if only stock plants are to be kept from which to procure cuttings in the spring, while when large beds are to be planted it has been the custom to grow specimen plants, both in bush, standard, and pyramid form, and use them year after year, giving them greenhouse accommodation during the winter. The tendency now is to rely more and more on the hardier flowers, such as Antirrhinums, which make quite a good display in

the flower-beds. Asters, Clarkias, Godetias, *Nemesia Suttoni*, and Stocks, treated as half-hardy annuals are excellent. Sweet Peas sown in pots or boxes in February and planted in April are excellent for furnishing a display in large beds. Pentstemons in such varieties as *George Home*, *Mrs Coats*, and *Mrs Hutton* will flower from June to October if planted in beds that have been well worked and liberally manured. If the beds are hoed frequently they will not require watering. Chrysanthemums of the early flowering class will provide a magnificent display in the autumn, the healthiest roots being, of course, lifted after flowering, and wintered in a cold frame to provide cuttings from which to raise young plants in the spring. Violas in variety will flower continuously throughout the summer if the seed pods are removed weekly. All the above hardy flowers can be raised annually either from seed or cuttings without fire heat; they therefore constitute the most useful subjects for furnishing the flower-beds of the future.

For further notes on this type of bedding see articles on *Bedding Out*, *Bedding Plants*, *Bedding Schemes for Summer and Winter*, etc.—T. A. S.

BEDS AND BORDERS, Areas of.—See Areas of Beds and Borders in *Arithmetic and Gardening*.

BEE ORCHIS (*Orchis apifera*).—See note at end of *Hardy Orchids*.

BEE PLANTS, Lists of.

The present-day bee-keeper must grow largely those plants whose flowers are rich in nectar if he is to have the large amount of honey he desires. The following classified lists contain all the best bee plants, and will be useful to those beginners who are at a loss as to what to grow for their bees :—

Annuals.

Alyssum maritimum.
Borago officinalis.
Centaurea Cyanus, and moschata.
Clarkia pulchella.
Coreopsis tinctoria.
Cynoglossum Wallichii.
Eschscholzia californica.
Gilia tricolor.
Helianthus annuus.
Iberis coronaria.
Impatiens glandulifera.
Limnanthes Douglasii.
Nemophila insignis, and maculata.
Nigella Damascena.
Phacelia campanularia, tanacetifolia, and viscida (Syn. *Eutoca viscida*).
Reseda odorata.
Saponaria calabrica.
Schizopetalon Walkeri.
Silene pendula.
Tropaeolum majus and minus.
Whitlavia grandiflora (Syn. *Phacelia Whitlavia*).

Biennials.

Campanula Medium (Canterbury Bells).
Cheiranthus Cheiri (Single Wallflower).
Echinops sphaerocephalus.
Erysimum perofskianum (often called *Cheiranthus Allionii*).
Myosotis (all species of Forget-me-not ; really perennials but generally grown as biennials).
Verbascum Thapsus.

Perennials.

Ajuga reptans.
Althaea rosea (single).
Alyssum saxatile.
Anchusa italica.
Arabis alpina (single).
Asclepias syriaca (Syn. *A. Cornuti*).
Aster (Michaelmas Daisies, all species).
Aubrietia graeca.
Campanula (most species).
Echinops Ritro.
Hedysarum coronarium.
Helleborus niger.
Malva moschata.
Polemonium caeruleum.
Polygonum sachalinense.
Primula veris, and vulgaris.
Sedum acre, anglicum, major, spectabile, and Telephium.
Spiraea Aruncus, Ulmaria.
Stachys lanata.
Symphytum asperrimum.

Verbascum phoeniceum.
Veronica Teucrium.
Vinca minor.
Viola odorata and tricolor.

Hardy Shrubs.

Berberis (most species).
Calluna vulgaris (Common Ling).
Deutzia crenata and gracilis.
Erica carnea, and cinerea.
Lonicera Caprifolium and tartarica.
Ribes sanguineum.
Robinia pseudacacia (small tree).
Symphoricarpus racemosus.

Bulbous and Tuberous Plants.

Colchicum autumnale.
Crocus vernus.
Eranthis hyemalis (Winter Aconite).
Fritillaria Imperialis.
Scilla sibirica.

L. B.-W.

BEE-TREE (*Tilia heterophylla*).—See *TREES*.

BEECH FERN (*Polypodium Phegopteris*).—See *FERNS AND FERN GARDENING*.

BEECH ROOT ROT.—See *DISEASES OF PLANTS*.

BEECH WHEAT (*Fagopyrum cymosum*).—See *FAGOPYRUM*.

BEEFSTEAK FUNGUS.—See OAK-TONGUE under EDIBLE FUNGI in *FUNGI : EDIBLE AND HARMFUL*.

BEES IN THE GARDEN.

One hundred years ago the little brown bees and their straw skeps were essential features in the gardens of both cottager and squire. To-day the reverse holds good, and owing to a variety of causes the bees and their hives are conspicuous as a rule by their absence, and we are the poorer for it. Gone in great measure is our delicious native honey, and with it went, although only few are aware of it, a good percentage of our fruit crop.

As a fertilising agent among fruit blossom the bee has no equal, and its value in this capacity exceeds even its value as a producer of honey. The grower of fruit should be a bee-keeper, for without their aid he will certainly not get full crops, while any honey he secures will rank as clear profit.

"Bees in the garden" is not always a synonym of "honey in the cupboard," but it should be, for it is largely a matter of a little intelligent attention at important times. The requisite knowledge is easily gained, and the sum total of all the time needed for the care of a small apiary would only amount to a few hours for the whole of the year.

It is best on the whole for beginners to commence with swarms obtained as early in the season as may be and hived in new frame hives. The hives should be placed in a secluded part of the garden, preferably with a southerly aspect. It will be all for the best if they back up to a path, for there will then be no need of walking upon cultivated ground during manipulations. The ground around the hives should be kept clear of weeds and tall-growing crops, while at the same time a little overhead shade will be beneficial in hot weather.

By commencing with swarms, new hives and appliances, there is much less danger of contracting bee disease, which unfortunately exists in many localities. Speaking of appliances, a smoker, veil, and graduated bottle-feeder are all that will be needed for the first year, if a sound text-book be excepted. During the first season it is not usual to secure much honey from swarms, but sound colonies are formed which are good for useful work in future years.

In a small apiary the bees require little attention from May to September. The super cases used for honey are put in position and added to as the need arises. Beyond that little is required unless a swarm should issue. This is often caused by overcrowding in the hive, and most frequently occurs in June, sometimes in the latter part of May, and rarely later than the early part of July. The hiving of a swarm is a formidable proposition to the novice, but there is nothing at all terrible about it. Never are bees more harmless than at that time, and stinging is the last thing they think about.

In average districts good colonies should produce fifty or sixty pounds of surplus honey per annum, but this would be a low estimate in some localities. The writer has taken from 150–200 lb. from single colonies in exceptionally good years.

Bees should be fed and prepared for winter in September, and if this is properly done no further attention should be necessary until April. During this period the bees are more or less semi-dormant, and any interference is to their detriment.

The fear of stings is a bar to the

keeping of bees in many gardens, but it is an exaggerated evil. Bees do not sting as a rule for the love of inflicting pain, but only when in their opinion danger threatens. If the hives stand in a quiet part of the garden a sting is a remote possibility. Bees dislike nothing so much as rush and bustle, quick nervous movements, and strong smells such as the bruising of onions, etc., in their vicinity. These little weaknesses on their part are so trivial as to warrant no one in refusing them admittance, while the good work they do for their owner is rarely credited at the full value.

Some bees are much quieter than others, but if it be found that a colony is of an irritable disposition, there is an easy remedy in re-queening it from a quieter strain.—H. G.

[When the gardener is unfortunate enough to get stung it is important to remember to extract the sting. A little ammonia or blue from the blue-bag rubbed on the wound will then quickly soothe it.—EDITOR.]

BEET.—See *BEETROOT.*

BEET CARRION BEETLES. — See *INSECT PESTS.*

BEET FLY.—See *INSECT PESTS.*

BEET, SEAKALE or SILVER (*Beta Cicla.* Nat. Ord. Chenopodiaceæ).—This is distinct from Beetroot, and is grown exclusively for its huge leaves, the midrib of which, if well grown, is very broad and of great length. When these leaves are divested of all the green, which by some is used as Spinach, the midribs are boiled and treated exactly as is usual for Seakale. As this crop comes in at a different period of the year, it usually finds favour with those who highly prize the real Seakale.

The soil for this crop should be well manured; seed may be sown in April in rows 18 ins. apart, allowing from a foot to 18 ins. between the plants. It bears transplanting fairly well.—F. R. C.

Spinach Beet is dealt with in the article on *PERPETUAL SPINACH.*—EDITOR.

BEET, SUGAR.—See *SUGAR BEET.*

BEETLES (INSECT FRIENDS).—See *INSECT FRIENDS.*

BEETROOT (*Beta vulgaris.* Nat. Ord. Chenopodiaceæ).—Although too often grown only for salads, when served up by those who understand their business, Beetroot makes a most excellent vegetable, a fact appreciated on the Continent, but too little known at home. It is one of the easiest, also one of the most profitable crops to grow, needing neither a rich nor an elaborately prepared soil, nor after attention when the seed has been sown. Large size in these being rarely a recommendation, richness is unnecessary; in fact, when preparing the bed for sowing, animal manure must rigidly be avoided, or the resulting crop will be so coarse or badly forked as to be almost worthless.

Culture.—The intended bed should be deeply dug, and the soil broken up very fine as the digging proceeds, this being done in order that the long root may speedily penetrate to such a depth as will secure the plant against check from likely summer drought.

Sowings may be made from 30th March to 8th June, sowings at the latter date invariably producing roots of most acceptable size, very suitable for use as a winter vegetable. The distance between the rows depends largely upon the variety, also upon the wishes of the grower; for all ordinary purposes, about 12–15 ins. between the rows, and 8–12¾ ins. between the plants in the row may be depended upon to give satisfactory results. Surplus plants obtained when thinning out may be transplanted into other quarters, and, providing rain soon follows, these plants may be expected to take root quickly, and in a very short time they will appear

to be no worse for the shift. Any variety found among the long-growing section will give good results in any soil providing it has been deeply dug, but where land is stony and only a few inches above rock or marl, these would be useless. For all such soils preference should be given to the Globe, or turnip-rooted varieties. These make all their growth above ground, the size or shape of the bulbs being but little affected by the nature of the soil below.

It always pays the grower to purchase none but a good strain of seed; much of that offered at a low price being mere rubbish, and if cooked, scarcely different in colour or character from Mangolds as grown for sheep or cows. Lift the crop in October or early in November, and either place the roots in a clamp or pit, as many large growers do with their potatoes, or put them under cover in a root-shed in heaps. Extra fine roots can be stored between layers of soil.

Good Varieties include Blood Red, Cheltenham Green Top, Dobbie's Purple, Frisby's Excelsior, Nutting's Dwarf, and Pineapple. Among the *Globe Varieties*, Crimson Globe or Model appear to be the best.—F. R. C.

See also *ORNAMENTAL VEGETABLES.*

BEGONIA (Nat. Ord. Begoniaceæ). This was formerly treated as a stove plant, but is now used largely for bedding purposes as a half-hardy perennial, and for conservatory decoration. It is about 12 ins. high, and enjoys a loose lumpy loamy compost, well enriched with decayed manure. Many of the species are tropical and can only be grown with success in a high temperature.

Culture.—Most of the florists' Begonias belong to the tuberous-rooted section. For bedding purposes the tubers should be started in a warm greenhouse or on a hot-bed, early in March. Shallow boxes filled with light, rich soil are convenient for this purpose, the tubers being lightly pressed into the compost, but not covered. Water should be given very sparingly till growth has started, and when the shoots are about half an inch long, the boxes may be moved to a cold house or frame, protection, however, being given against late frosts. Planting out can be safely done during the first week in June. The tubers should then be buried 2 ins. deep and the beds heavily mulched with short manure. Abundant moisture is required during summer, and shade from hot sunshine is desirable. With good culture the flowering season will last from mid-July till the advent of frost in autumn, when the tubers should be lifted and gradually dried off. They will winter safely if kept in boxes of dry soil in a frost-proof shed. For pot culture under glass the procedure is similar till growth is well started, when the tubers are potted up in 4-inch pots. The compost for this should be three parts fibrous loam, two parts leaf-mould, and one part each of decayed manure and coarse silver sand. Before becoming pot-bound the plants are given their final shift, and as they like plenty of root room, pots of 8-inch diameter are not too large for good-sized specimens. Cool culture, pinching off all early buds till thoroughly established, and abundant moisture with occasional doses of weak liquid manure, should ensure successful results.

Varieties.—Black Knight, H. W. Fry, Hon. Mrs R. Greville, Irene Tambling, John G. White, King Albert, Lady Arthur Nicholson, Lady Tweedmouth, Mrs J. D. Black-

more, Mrs Peter Blair, Old Gold, Princess Victoria Louise.—J. L. G.

NEW VARIETIES.

Begonia Fireflame. — A winter flowering sort, with orange-scarlet flowers, and broad, bright green leaves.

B. General Allenby.—A tuberous-rooted sort, with crimson-scarlet double flowers.

B. James Braid.—A tuberous-rooted sort, with cardinal red double flowers.

B. Lady Carew.—A tuberous-rooted sort, with rosy-scarlet double flowers.

B. Mrs C. F. Langdon.—A tuberous-rooted sort, with large pale orange-scarlet double flowers.

B. Mrs Harry Barton.—A winter flowering sort, with semi-double, creamy-white flowers, and broad dark green, shining leaves.

B. Mrs J. S. Brunton.—A tuberous-rooted sort, with salmon-pink double flowers, with a deeper coloured centre.

B. Mrs W. Cuthbertson. — A tuberous-rooted sort, with lilac-rose double flowers, the outer petals of which are frilled.

B. Norbury Park.—A winter flowering sort, with blush flowers of the *Gloire de Lorraine* type.

B. Queen of the Belgians.—A tuberous-rooted sort, with large cerise-pink double flowers.

B. Snowdrift.—A tuberous-rooted sort, with white double flowers.

W. J. C.

BELLADONNA. — A synonym for *ATROPA*, which see. See also *MEDICINAL HERBS*.

BELLADONNA LILY.—See *AMARYLLIS*.

BELLEVALIA.—Now included in the genus HYACINTHUS.

BELLFLOWER.—See *CAMPANULA*.

BELLIDASTRUM.—Now included in the genus *ASTER*.

BELLIS.—See *DAISY*.

BELLIUM (FALSE DAISY. Nat. Ord. Compositæ).—This genus includes several Daisy-like plants with rosettes of leaves. They are useful in the rock garden, though soon form rather large patches. They thrive in half-shady positions in gritty soil, and are propagated by division in the autumn or spring, or by seeds sown outside in the spring.

Bellium bellidioides.—This is an annual, but sows itself freely. Flowers white. Site half-shady. Soil gritty loam. Flowering Period, May to August. Height, 3 ins.

B. crassifolium.—This is a useful little perennial. Flowers yellow. Site sunny. Soil gritty loam. Flowering Period, July. Height, 6 ins.

B. minutum.—This is smaller than the above. Flowers white and yellow. Site half-shady. Soil gritty loam. Flowering Period, June to July. Height, 2 ins.

W. I.

BELLWORT.—See *CAMPANULA* and *UVULARIA*.

BENGAL QUINCE.—A name applied to the genus *ÆGLE*. See *SHRUBS*.

BENT GRASS (*Deschampsia flexuosa*). See *DESCHAMPSIA*.

BENT GRASS.—A perennial weed. For MEANS OF CONTROL see *WEEDS*. See also *AGROSTIS*.

BENTHAM'S STRAWBERRY TREE (*Cornus capitata*).—See *CLIMBING AND TRAILING PLANTS*.

BERBERIDOPSIS.—For the best species see *CLIMBING AND TRAILING PLANTS*.

BERBERIS.—For the best species see *SHRUBS*.

BERCHEMIA.—For the best species see *CLIMBING AND TRAILING PLANTS*.

BERGAMOT.—See *MONARDA*.

BERMUDA BUTTERCUP (*Oxalis cernua*).—See *OXALIS*.

BERMUDA EASTER LILY (*Lilium longiflorum eximium*).—See *LILIES*.

BERRIED ELDER (*Sambucus racemosa*).—See *TREES*.

BERTEROA.—Now included in the genus *ALYSSUM.*

BERYLLIS.—Now included in the genus ORNITHOGALUM.

BETONICA.—Now included in the genus *STACHYS.*

BETULA.—For best species see *TREES.*

BHOTAN PINE (*Pinus excelsa*).—See *TREES.*

BIENNIALS : Notes on.

There is no hard-and-fast line between an annual, a biennial, and a perennial. Annuals, that are sown in autumn, or sow themselves, will live through the winter and bloom like biennials. Seeds of the biennial Evening Primrose that lie in the soil all winter may germinate and reach the flowering stage late the following summer. Wallflowers and Sweet Williams are perennials, but give the best results when grown as biennials. The biennial *Gilia coronopifolia* does best sown early in heat and grown as an annual, and so of many others. Those who have the command of a heated greenhouse or make a hotbed can rear many things in this way, and plant them out when the weather becomes suitably genial. Other things can be reared in a cold frame, such as the Indian Pink (*Dianthus chinensis*), and bloomed outside in July and August. In inland districts, those who have no artificial heat can sow East Lothian and Brompton Stocks in July and preserve them in a cold frame till March or April, according to the weather; those on the sea-board can sow them at that time where they are to bloom, or transplant them. While biennials may be sown in May, June, or July, those who have not even a cold frame should select the earliest month to sow outdoors to enable the plants to grow to good flowering size. Wallflowers bloom in May, and must be sown during that month in the open air. If sowing is delayed until July the plants sometimes fail to reach flowering size the following year.

List of Biennials.—The following list contains those plants usually termed Biennials by gardeners. With the exception of *Ammobium alatum grandiflorum, Anagallis fruticosa, Anarrhinum bellidifolium, Blumenbachia coronata, Gilia aggregata* and *G. coronopifolia,* all are hardy.

Althaea caribæa.
Ammobium alatum grandiflorum.
Anagallis fruticosa.
Anarrhinum bellidifolium.
Anchusa capensis.
Bigelow's Aster (*Aster Bigelovii*).
Blumenbachia coronata.
Bromus brizaeformis.
Bellflowers (*Campanula sibirica, C. s. divergens, C. thyrsoides*).
Canterbury Bells (*Campanula Medium*).
Centaurea Fenzlii.
Chimney Bellflower (*Campanula pyramidalis*).
Chlora grandiflora.
Cretan Mullein (*Celsia cretica*).
Echinospermum marginatum macranthum.
Evening Primrose (*Œnothera biennis, Œ. lamarckiana*).
Foeniculum dulce.
Forget-me-not (*Myosotis alpestris*).
Foxglove (*Digitalis purpurea*).
Gilia aggregata, G. coronopifolia.
Grindelia grandiflora.
Hollyhock (*Althaea rosea*).
Honesty (*Lunaria biennis*).
Horned Poppy (*Glaucium flavum, G. f. fulvum, G. f. tricolor*).
Indian Pinks (*Dianthus chinensis*).
Meconopsis nepalensis.
Michauxia lævigata.
Mullein (*Verbascum olympicum, V. phlomoides, V. phoeniceum*).
Night Scented Stock (*Hesperis tristis*).
Salvia bicolor.
Stock (*Brompton, East Lothian, Queen*).
Sweet Rocket (*Hesperis grandiflora*).
Sweet Scabious (*Scabiosa atropurpurea*).
Sweet William (*Dianthus barbatus*).
Variegated Tree Mallow (*Lavatera arborea variegata*).
Wallflowers (*Cheiranthus Cheiri*).

J. F.

[Descriptions of many of these plants will be found under their English or their botanical names throughout the work.—EDITOR.]

BIFRENARIA.—See *ORCHIDS.*

BIG BUD.—See *INSECT PESTS.*

BIG RIVER ABUTILON (*Abutilon megapotamicum*). — See *CLIMBING AND TRAILING PLANTS.*

BIG SHELL-BARK (*Carya sulcata*).—See *TREES.*

BIGELOW'S ASTER (*Aster Bigelovii.* Nat. Ord. Compositæ).—We give this plant a paragraph to itself as it is the only biennial Aster which is worth growing. There is no difficulty in its culture, a stock of plants being easily raised by sowing seeds in a small bed during May and transplanting the seedlings into sunny positions, in well-drained soil, where they are to remain. The flowers are lilac, with a yellow centre, 2½ ins. across; they are produced in flat-topped trusses, and are very handsome. The blooming period is throughout the summer, and the plant averages 2½ ft. in height.—J. F.

BIGNONIA.—In part a synonym for *TECOMA*, which see. For CLIMBING SPECIES see *CLIMBING AND TRAILING PLANTS.*

BILBERRY (*Vaccinium Myrtillus*).—See *SHRUBS.*

BILL-HOOKS.—See *GARDEN TOOLS.*

BINDING PLASTER.—See *MORTAR.*

BINDWEED.—See *CONVOLVULUS.*

BINDWEED (*Convolvulus arvensis*).—A strong growing perennial weed. For MEANS OF CONTROL see *WEEDS.*

BINDWEED, BLACK (*Polygonum Convolvulus*).—An annual climbing weed. See *WEEDS.*

BIOTA.—Now included in the genus *ASTER.*

BIRCH.—See the genus BETULA in *TREES.*

BIRD CHERRY (*Prunus Padus*).—See *TREES.*

BIRD'S-EYE PRIMROSE (*Primula farinosa*).—See *PRIMULA.*

BIRD'S-FOOT.—See *ORNITHOPUS.*

BIRD'S-FOOT TREFOIL.—See *LOTUS.*

BIRD'S TONGUE (*Senecio paludosus*). See *SENECIO.*

BIRDS AND THE GARDEN.

We are perhaps apt to notice the relative amount of harm more than the good done by these beautiful and cheery inhabitants and visitors of our gardens, therefore we should judge the various kinds fairly, by means of careful observation.

Many of the wilder and more timid birds hardly ever enter a garden, especially if there is a house near; cats also scare birds. *Owls* and *Hawks*, "Nature's mouse-traps," will very rarely be seen unless the garden is near a wood. The locality and position of the garden influence its bird visitors. In many gardens the handsome *Bullfinch* is never seen, whereas in other gardens, perhaps near a wood, they may be most destructive to gooseberries, and plums (especially greengages), by pecking out the buds, in consequence of which nearly the entire crop of fruit is lost and the symmetry of the bushes and trees is spoilt through loss of leaf. The same may be said of the *Hawfinch*, a fine and rare bird, except in certain localities, where it eats peas at a great pace, also cherries and bullaces; it pecks apples and pears to get at their pips, and attacks plum and pear buds. The *Jay* in like manner comes from the woods, and though a sad thief of green peas, cherries and other fruit, it is useful to the garden in eating cockchafer-beetles, and other insects, also blackbirds' eggs, as there are generally too many blackbirds for the good of the fruit of the garden.

Rooks and *Seagulls* hardly ever enter the garden, and the *Jackdaw* seldom, but it may clear cherries or walnuts from an orchard; in the field they destroy newly-sown peas and grain, yet are useful if not too numerous, as they eat leather-jackets, wireworms, and cockchafer grubs, but they will completely clear nests of small birds of both eggs and young.

The *Magpie* is a rare bird in many districts; it goes for cherries like the rook, to which it is allied, but like owls and hawks should never be destroyed.

The *Plover* is another bird common in fields, but seldom seen in the garden; it is a valuable bird to the cultivator of land, and does no harm.

Coming now to the birds which most frequent our gardens, of these the *House Sparrow* is the commonest; it is very hardy, and is so daring that it finds food in winter where

other birds fear to approach; its rate of multiplication also is great compared with other birds, which from a garden point of view seem to be more useful. The house sparrow in feeding its young does take a certain number of caterpillars and other insects, but as soon as the feathers of the young birds are grown, they are fed on grain, seeds being the staple food of the mature bird. Professor F. V. Theobald tells me House Sparrows and other finches eat great numbers of the caterpillars of the winter moth (which defoliate fruit trees), and that the sparrow eats all kinds of caterpillars except the hairy ones, which are only eaten by that interesting bird, the *Cuckoo*. In gardens the House Sparrow interferes severely with new-sown seed and young pea shoots; in the winter and early spring it pecks the buds of gooseberries and red currants, and sometimes those of plums, damsons, and cherries. It pulls to pieces the flowers of some varieties of cherries and plums, perhaps for the sweet juice, but apparently for mischief. It sometimes eats caterpillars on fruit trees, aphides on damsons, weevils on peas, and occasionally a white cabbage butterfly, but the general opinion is that the good it does in a garden even at a most liberal estimate is far out-balanced by destructiveness. The late Miss E. A. Ormerod, one of the wisest and kindest of economic naturalists, considered House Sparrows to be too numerous for the good of both farm and garden.

The *Blackbird* is the worst thief of fruits, including green and ripe strawberries, red currants, gooseberries, raspberries, apples, cherries, plums, tomatoes, mulberries, figs, and loganberries. When not eating fruit, it feeds on worms, slugs, and insects; these birds are considered to be increasing in number.

The *Starling* is very destructive to cherries, strawberries, pears, apples, plums, raspberries, gooseberries, and currants; this bird also appears to be increasing rapidly. It is a valuable insect destroyer on pasture land, foraging among the grass for leather-jackets (larvæ of the Crane-fly) and wireworms.

The sociable little *Robin Redbreast* feeds chiefly on worms, insects, and ground grubs, but it also takes a few red and white currants, cherries, strawberries, and grapes under glass, taking a peck at each fruit, thus doing considerable harm in a short time.

The *Song Thrush* destroys large quantities of strawberries, cherries, red currants, and raspberries, but does not, like the blackbird, peck apples and plums on the trees; its damage is worst in dry summers and autumns, when its natural food consisting of worms, snails, grubs, and slugs is hard to get; it is useful in winter.

The *Missel Thrush* is among the worst fruit thieves, a voracious eater of cherries, also pears, apples, plums, damsons, red currants, ripe gooseberries, strawberries, and raspberries, yew, holly, and mountain ash berries; it is fond of black currants, which most birds avoid. Except in fruit time it is a very useful bird.

The *Chaffinch* attacks plum and pear buds, and bites off many plum blooms presumably to get nectar; in company with the House Sparrow it pecks gooseberry buds, destroys garden seedlings, but eats many caterpillars, also aphides. The *Greenfinch* is in habit very similar to the chaffinch, except that it eats very few insects and is if anything more destructive to sprouting crops; it eats weed seeds, and thereby distributes certain weeds; it eats the seed from turnip, cabbage, and radish plants, and the buds of pear, plum, and gooseberry.

The *Wood Pigeon* is a plague, and is said to do no good; it is a very greedy feeder, destroying cabbage and turnip leaves in winter; it roots up seeds such as beans and corn, eats green gooseberries in quantities, also clover leaves. This bird should be ruthlessly destroyed and made into pies.

The *Lark* is destructive to peas when coming up; in a hard winter it strips autumn-planted cabbage, Brussels sprouts, also spinach. It pecks early strawberries. When not engaged as above, it is probably doing good.

Martins, Swallows, and *Swifts.*—These rapid fliers whilst in flight catch winged aphides, moths, and other flying insects, and are therefore very useful.

The gentle *Hedge Sparrow* is said to do "All good and no harm."

The *Pied Wagtail* is good in every way, eating insects and small molluscs.

The *Brown Linnet* is destructive

to cabbage, radish, and all other seed.

The *Blue Tit* is a great feeder on insects, many of which are injurious; mussel scale on the trunks of apple trees is largely eaten by tits, also scale on gooseberry, black and red currants. The Blue Tit, however, pecks holes in a good many apples, pears, plums, also in grapes in a vinery.

The *Wren* is strictly insectivorous, constantly picking up insects and their eggs on the branches of trees, and does no harm.

The *Cuckoo*.—"Let him be, he lives a useful life." It eats immense quantities of caterpillars during its brief stay in parts of this country before its return to Africa.

The *Blackcap* eats all manner of insects, also raspberries, cherries, and figs.

The *Whitethroat* and other *Warblers* eat raspberries, sweet cherries, grapes, and figs when ripe; otherwise they are insectivorous.

The *Spotted Flycatcher* is wholly beneficial, destroying insects, including aphides and the gooseberry sawfly.

The *Tree Creeper* is harmless and a good insect destroyer.

The *Nuthatch* is beneficial, only taking a few filberts and cobnuts.

Undoubtedly birds eat a great many injurious insects, but several of the most troublesome are little if at all eaten by birds; such are the Big Bud Mite of black currants, Woolly Aphis on apple trees, the larvæ of the Gooseberry Sawfly and Magpie Moth.

Although some kinds of birds eat great quantities of aphis and apple sucker, spraying is more effective where it is possible. Gooseberry bushes may be protected to some extent from birds pecking out the buds by limewash spraying; plum trees may be similarly treated, but a strong pump is necessary in order to apply the lime sufficiently thickly. As a result of the experience of generations of observant gardeners, and the more recent study of the life-histories of insects by economic naturalists, most of the garden pests may be got rid of by means of spraying with insecticides.—C. H. H.

BLUE-BOTTLE.—A name applied to *CORNFLOWER*, which see. See also under CORNFLOWER in *MEDICINAL HERBS*.

BLUE CUPIDONE (*Catananche caerulea*).—See *CATANANCHE*.

BLUE DAISY (*Globularia vulgaris*).—See *GLOBULARIA*.

BLUE-EYED GRASS (*Sisyrinchium Bermudianum*).—See *SISYRINCHIUM*.

BLUE GUM (*Eucalyptus globulosus*).—See *EUCALYPTUS*.

BLUE JACK (*Quercus cinerea*).—See *TREES*.

BLUE LUPINE (*Lupinus polyphyllus caeruleus*).—See *LUPINE*.

BLUE MEADOW GRASS (*Poa compressa*).—See *POA*.

BLUE MOONWORT. — A name applied to the genus *SOLDANELLA*. See note at end of article on that genus.

BLUE MOUNTAIN DAISY (*Aster alpinus*).—See *ASTER*.

BLUE MOUNTAIN SWEET (*Ceanothus azureus*).—See *CLIMBING AND TRAILING PLANTS*.

BLUE OAK (*Quercus Douglasii*).—See *TREES*.

BLUE ROSE (*Veilchenblau*). — See under RAMBLER ROSES in *ROSE CLASSES*.

BLUE SOWTHISTLE (*Lactuca alpina*).—See *LACTUCA*.

BLUE SPRUCE (*Picea pungens glauca*).—See *TREES*.

BLUE SQUILL (*Scilla sibirica*).—See *SCILLA*.

BLUE STONE.—See COPPER SULPHATE in *COPPER AND CUPRUM COMPOUNDS* and *WEED KILLERS*.

BLUE STONECROP (*Sedum caeruleum*). See *SEDUM*.

BLUE THROAT-WORT (*Trachelium caeruleum*).—See *TRACHELIUM*.

BLUEBELL (*Scilla festalis*). — See *SCILLA*.

BLUEBERRY (*Vaccinium corymbosum*).—See *SHRUBS*.

BLUET.—See *CORNFLOWER*.

BLUMENBACHIA (Nat. Ord. Loasaceæ).—The most important garden plant in this little family of annuals is *B. insignis*, the only one that is hardy. Seeds may be sown in early spring where the plants are to remain, or plants may be raised in gentle heat to ensure a longer season of growth. The white axillary flowers are about 1 in. across carried on rather long stems.

Blumenbachia coronata.—This half-hardy biennial species produces large glossy white flowers in June, on erect stems, about 18 ins. high, and these nestle amongst the shiny metallic leaves. Seeds may be sown in gentle heat early in March, and planted out in May to bloom during the summer ; or they may be sown in a cold frame from May to July, and kept there till the weather becomes genial in May following, and then planted out.

B. insignis (Syn. *Loasa palmata*). —This is a low climber bearing white flowers in June. Some of the hairs on its stem have a stinging character, hence it is a useful plant for a low fence and a position where unlawful hands are wont to make free with flowers and fruits to which they have no right.—C. H. C.

BLUSHER. — See EDIBLE FUNGI in *FUNGI : EDIBLE AND HARMFUL*.

BOCCONIA.—See *PLUME POPPY*.

BOG BEAN.—See *MENYANTHES*.

BOG PIMPERNEL (*Anagallis tenella*). See *ANAGALLIS*.

BOG RUSH (*Schoenus nigricans*. Nat. Ord. Cyperaceæ).—This is a hardy plant of easy culture which may be grown in the more boggy portions of the water or wild garden. Its height averages about half a yard.

BOG VIOLET (*Pinguicula vulgaris*).—See *PINGUICULA*.

BOG AND WATER GARDEN PLANTS. See *WATER GARDEN: PLANTS FOR THE*, and under ROCK PLANTS FOR BOG AND WATER GARDENS in *ROCK PLANTS FOR ALL PURPOSES*.

BOIS DE STE. LUCIE (*Prunus Mahaleb*).—See *TREES*.

BOISDUVALIA. — Now included in the genus ŒNOTHERA.

BOLET.— See under DAINTY BOLET among EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

BOLTONIA (FALSE STARWORT. Nat. Ord. Compositæ).—This is one of the lesser known and not largely grown hardy herbaceous perennials. However, it is well worth inclusion in borders where anything like a representative collection of hardy herbaceous plants is attempted. It will succeed well enough in any good moist garden earth, and may be used for shady shrub, and wild garden borders, or for sunny perennial parterres. It is not hard to increase it by division of the roots any time from November to March, and it may be successfully planted at any time within that period.

What to Grow. — Only three species are included, though fanciers may care about others. Of these *Boltonia asteroides* is decidedly the most desirable, as well as being the sort most often grown. There are several sorts of this, and the range of colour includes pink, purple, violet, and white. This sort blooms from July onwards into August, and may extend for a further period into September. The range of height also varies according to circumstances from 2½ ft. to 5 ft. The two other species, *B. indica* and *B. latisquama*, are white and a kind of violet-blue respectively. They bloom from late August onwards, and their height varies.—E.

BONES.

The uses of bones in the form of bone-meal, bone-dust, bone-flour, and what is known as "Half-inch Bones" are very limited, and it is exceedingly doubtful whether they do as much good as is imagined. The phosphates in these forms of bones are quite insoluble, though after a lengthy period they begin to dissolve very slowly, and beyond the fact that bone-meal and bone-dust contain a little organic matter, it is difficult to see where the fertilising value comes in. They are used freely by some people as a dressing for lawns and herbaceous borders, also for potting; but soluble phosphates would probably be very much better, and much less would have to be used.

Dissolved Bones are quite different. Most of this material is soluble in water, or in soil water, and it provides a cheap and very effective phosphatic fertiliser of which full advantage should be taken. About 1 cwt. of commercial sulphuric acid (free from arsenic) is required to dissolve 3 cwt. of bones, and the safest way of working is to make a heap out of doors on a concreted floor and surround it with coal ashes. Opinions differ as to the actual procedure, but we prefer to spray the heap of bones very thoroughly with the coldest well or spring water, and then slowly to shoot the acid out of the kegs it will arrive in, on to the bones. It is desirable to wear glasses and a sufficiently large and thick mask, also thick gloves for this work, since if a drop of the acid should jump up on to the naked hand or face a bad burn will be produced. The heap should then be covered up with large slates (the acid does not dissolve slate or glass though it dissolves all metals save lead and platinum), and left for a day. After this the whole heap is turned over on to another section of concrete

flooring and mixed together. A further day for mellowing is then desirable, after which the lot is passed through a riddle and stored in stone or porcelain tubs in a dry place till required for use. There is another method, namely, that of pouring urine into a barrel of bones, but as this is decidedly smelly and none too healthy we do not describe it in detail here. Dissolved bones can be used for the same purpose and in the same quantities as superphosphate of lime.

E.

See also under PHOSPHO-NITROGENOUS MANURES in *MANURES*.

BORAGE (*Borago*. Nat. Ord. Boraginaceæ).—All members of the Borage family are hardy, and most of those in cultivation are annuals, or best treated as such. The COMMON BORAGE (*B. officinalis*) is generally relegated to the herb border, but it again came into popular favour since herb gardens have become features of many large private and public establishments. When bearing its drooping panicles of blue or purple-blue flowers in June and July, it is quite attractive and has the additional merit of being useful in such summer beverages as Claret Cup and Cool Tankard. It is quite easily raised from seeds sown in the open ground in March, but the seedlings should be thinned to 1 ft. apart. There is also a white-flowered form of this British plant listed as *B. officinalis albiflora*. Both plants should be grown freely where bees are kept; they average 1½–2 ft. high. *B. laxiflora* and *B. longifolia* are both blue-flowered species. The former is a trailer, and blooms throughout the summer, while *B. longifolia* flowers in July and August and grows about 1 ft. high.

One useful PERENNIAL SPECIES may be mentioned, namely, *Borago cretica*. This bears blue flowers in May or June, and averages 12 ins. in height.

There are a number of other species which are excluded for various reasons. The majority are little grown and are thus outside the scope of the present work.

C. H. C. & E.

BORAGO.—See *BORAGE*.

BORDEAUX MIXTURE.—See *SPRAYING MIXTURES* and *FUNGICIDES*.

BORDER CARNATION.

By this we mean the well-known Carnation grown as a border plant, as distinct from the Malmaison Carnation, the Margaret Carnation, or the Perpetual Flowering Carnation. The culture of Border Carnations is fully described in our article on *CARNATIONS*.

BORDERS, AREAS OF.—See AREAS OF BEDS AND BORDERS in *ARITHMETIC AND GARDENING*.

BORDERS, HERBACEOUS.—See the two articles on *HERBACEOUS BORDERS*.

BORDERS, MIXED.—See *MIXED BORDER, THE*.

BORECOLE, or KALE (*Brassica oleracea fimbriata*. Nat. Ord. Cruciferæ).—Owing to the extreme hardiness and general good quality of all this class they enjoy universal popularity among all lovers of fresh vegetables. Many of the best known have a decided ornamental as well as a utilitarian value, and the plants appear to do almost as well in smoky towns as in country districts.

Culture.—Seeds of any of the above may be sown from the middle of March until the first week in May. Transplanting twice is advised, the first when the plants are a few inches high, when a good open, well-manured spot should be chosen. Plant in rows 6 ins. apart, leaving

4 ins. between each plant. Give plenty of water, and plant out into permanent quarters as early in July as it is possible. Plenty of manure should be provided, and water must be given freely until the roots have taken well hold of the soil. Whenever possible allow 30 ins. apart each way, 6 ins. less where the soil is very poor or space limited.

Varieties.—The *Arctic Curled, Cottagers,* or *Dwarf Scotch* are probably the most popular, and these varieties should be largely sown, for use from November onward.

Quite distinct from these, and no less hardy, coming into use later in the season, is what is known as the DRUMHEAD KALE. This forms a large close head very like a cabbage, the outer leaves finding favour with many, chiefly owing to their availability for use after all green has been removed, as a substitute for Sea-kale, while perhaps the most delicate flavoured in the whole section is found in the *Asparagus* or *Buda Kale,* known in some districts as *May Greens,* the long shoots of this during April and early May being almost equal to Asparagus.—F. R. C.

BOTANY FOR GARDENERS.

What has botany to do with practical gardening ? The beginner soon learns what the cultivation of flowers means practically, but it is not so easy to be a botanist.

Botany includes the *study* of *all* plants and not only those in gardens; and to understand *how* a plant grows one must learn all about its different parts, such as the roots, stems, and branches, leaves, flowers, fruits, and seeds. Not only all their different forms, but the internal structure by means of a microscope. We require to know *how* a plant grows from a seed until it is full grown and can produce seed itself.

Let us then briefly consider the parts of a plant, namely the roots, stems, and branches, leaves, flowers, fruits, and seeds, from a botanical point of view. Then we shall see what botany has to do with gardeners. It is clear that if a gardener has to cultivate plants, he should know what they require in order to grow healthily and bear fine flowers or good fruit. It is the study of botany which teaches us this.

The first group of parts of a plant to be considered are called the *Vegetative* "organs." These are concerned with growth only as a rule, while the flowers and fruits are the *Reproductive* "organs."

Let us begin with the root. Dig up a small herb, and the root will be seen to be continuous with the stem, as of a wallflower, shepherd's purse, or groundsel; but it differs in not being green. Moreover, it branches two or three times into fine rootlets. The tip of each end is a point like that of a pin.

Now this point has to grow and so push the soil aside. Being extremely delicate, its "growing point" must be protected, so a tiny "root-cap" consisting of dead cells is constantly being renewed to protect it. This can only be seen under a microscope, which no botanist can do without.

He will also see the cells on the surface extend as fine hairs or tubes, closed at the end. These are for absorbing water from the soil.

Now the gardener will understand that if we wish to transplant a herb or larger plant, it is most important to preserve the finest root-ends, because if they be broken off, the plant cannot get any food till they are renewed, which takes time.

Such is the first practical lesson the gardener has to learn from botany.

The next thing is to know what substances, *i.e.* minerals, are necessary for a healthy plant. These are absorbed, dissolved in water, by the "root-hairs" mentioned above. But this is a long story and will be learnt elsewhere.

The next question is, after having taken up its mineral food in water, how does the water travel up the plant to get to the leaves, etc. ? For no part can live without it; as we can see how lettuce leaves "wilt," as the Americans say, if water is insufficient.

We must use the microscope again, and we discover little tubes called "vessels" running up the stem and branching off into the branches and up the so-called "veins" of the leaves. The latter subdivide again, so that every bit of the leaf can be nourished.

The leaves are the most important "organs," for they not only *digest* the food brought up by the "sap," but get more out of the air.

As the reader may know, we breathe in order to take in the oxygen out of the air; but we do not breathe it out again but expire "carbonic acid" gas. This is not poisonous, but "suffocating," and renders the air very impure if a room be full of people and with insufficient ventilation. Now all green parts of plants, as leaves and branches, take in this gas and use it as food, and in exchange discharge oxygen into the air; so that we have to thank all sorts of vegetation for purifying the air, which the animal kingdom is obliged to make impure.

But how do plants do it? Botanists have investigated the process. The reader will find a full account of it in the article on *Plant Physiology*. All we can say here is, that light is the means by which the plant "assimilates" or converts carbonic acid gas into starch. And out of this it builds up its various structures.

We may go a step further. Every gardener knows that colourless light can be divided up into red, orange, yellow, green, blue, and violet-coloured rays, as seen in a rainbow. To find out if there was any difference in using coloured glasses, I grew lettuces from the young state, 4 ins. high, till full grown. Under red the stems were about 16 ins. long; they were shorter and shorter, till one came to the blue and violet, under which they were *nearly* as short as in open ground.

This showed that they wanted all the coloured rays *i.e.* ordinary colourless light.

To ascertain how much solid matter was made, the plants were dried, and the greatest amount was found to be under yellow and blue, and least under green glass.

This botanical experiment revealed the fact that it is unwise to use any *coloured* glass in conservatories. My experiment was independently corroborated at Kew, for the authorities had put green glass in the ferneries, but they found that it proved so injurious, that it had to be replaced by uncoloured glass. Such is another lesson from botany.

Physiological botany—of which the preceding is an example—teaches much. How comes it that the wild carrot, parsnip, and beet are so totally different from the cultivated plants? In the wild state they are weeds with long, slender, but tough roots. By sowing the seed in a rich garden soil, the seedling soon discovers what a bountiful supply of food it has. It grows apace; its leaves grow larger, make more starch or sometimes sugar, than it used to require, so the root begins to enlarge as a storehouse for it. Moreover, it goes on at this work longer than when it grew in a dry, poor soil, and, so to say, forgets to blossom the first year, and consequently it lives through the winter. In the second year the time has come to produce seed, so it uses up all its stores of food, bursts into blossom and makes seed, then it dies. It has thus become a "biennial" from having been an "annual."

And such is the botanical explanation of the origin of our "root-crops." The late Mr James Buckman, when Professor of Botany at the Cirencester Agricultural College, raised from seed from the wild parsnip, in 1847–51, a fine kitchen root. He handed over the seeds to Messrs Sutton & Sons, and after "improving" it, they issued it as the now well-known "Student" parsnip, having been first raised in the botanic gardens of the College.

But leaves do more than "assimilate" carbonic acid gas, they must *breathe* or "respire." This they do at all times, night and day, as it is induced by heat and not by light; but the amount of this bad air or carbonic acid which they "give out" is small compared with the amount of the same gas which they assimilate.

There is yet another "function," as we say: they must "perspire" as we do. This is called in botany *Transpiration*, and my experiments with the lettuces proved that the greatest amount of water given off was under red and violet glasses.

It is not *heat*, therefore, but *light* which is required for this process; though heat will, of course, cause water to "evaporate" from all tissues, dead or alive. But that is a different thing from transpiration, as lettuces will "wilt" on a hot bright day, but not on a similarly bright day which is not so hot.

Now let us come to the flowers. We all know that these precede the making of seed. The first thing a gardener should know is the structures of as many flowers as he can get. He must have some little elementary

book on Botany to teach him.[1] It is important to understand how a flower can produce seed. To do this, he must be familiar with the *stamens* and *pistil*, the innermost parts of the flower, for "crossing" and "hybridising," as these processes form an essential part of the gardener's profession.

At the same time the gardener should learn how plants are *classified* by the structure of their flowers and fruits.

If, for example, he had learned how to fertilise one sweet pea by another of a different colour, he might think he could get a "cross" between a large-flowered *Ranunculus* with a *Potentilla* or *Geum*, as they look very much alike. But if he has learnt a little "Systematic Botany," *i.e.* Classification, he would know that the first was not in the same "family" as the two latter, and that no members of distinct families can be "crossed."

The above are the most obvious facts which a gardener learns from botany. While "Systematic" Botany teaches him "Classification," "Physiological" Botany explains *how* a plant grows, and what are its requirements to enable it to live a healthy life and leave an abundant offspring.

Lastly, what has been said above about root-crops will show how plants can *change* in form, size, etc., and so render to us far more useful results either for food or ornament. This is called "Evolution."

As we can "evolve" new forms in the garden, so if the student extended his studies outside the garden, and observed wild plants growing under various conditions — as in very dry situations, say, on heaths, or hot deserts; or again on mountains and in cold arctic regions—he could not fail to see how certain plants closely resemble others which may not even belong to the same family. Similarly plants growing in water assume the same characters, though of different families altogether; so that without the flowers, which are not affected by the change, they could be scarcely recognised.

What is the inference? It has been proved by observers in all parts of the world that plants change their forms in "adaptation" to their changed surroundings—such as drought, great heat, bog-land, water, high mountains, and the arctic regions, etc.

Hence when a gardener makes a rockery he looks to the Alps for examples of *dwarf* plants of many different kinds; for this is one of the features all high Alpine and Arctic plants have acquired.

In former days botanists did little more than collect plants and name them. *Now* we study the conditions in which they live. This is called *Ecology*. As *Economy* means the right *ordering* of a home, so the former is the *study* of the *home* of the plant.

Such is the study of botany, and the gardener will see that much he has to do with is what was learnt from the botanist and *not* from the cultivator.—G. H.

See also *EDUCATION AND GARDENING*.

BOTRYANTHUS.—Now included in the genus MUSCARI.

BOTRYTIS CINEREA. — See *DISEASES OF PLANTS*.

BOTTLE BRUSH (*Metrosideros floribunda*).—See *METROSIDEROS*.

BOTTLE GOURD.—See *ORNAMENTAL GOURDS*.

BOTTLE GRASS (*Setaria viridis*).—See *SETARIA*.

BOTTLING FRUIT. — See *FRUIT BOTTLING AND PRESERVING*.

BOTTLING PEAS AND BEANS.—See *VEGETABLE BOTTLING*.

BOTTLING VEGETABLES. — See *VEGETABLE BOTTLING*.

BOUR TREE (*Sambucus nigra*).—See *TREES*.

BOURBON LILY.—See footnote to *Lilium candidum* in *LILIES*.

BOURBON ROSE (*Rosa bourbonia*).—See *ROSE SPECIES*. For the best varieties see *ROSE CLASSES*.

BOURSAULT ROSE. — See under *Rosa alpina* in *ROSE SPECIES*. For the best varieties see *ROSE CLASSES*.

BOUTELOUA (GRAMA GRASS. Nat. Ord. Gramineæ). — A genus of hardy perennial grasses grown very easily in ordinary soil but of little garden value. The best known species are *B. racemosa* and *B. Rothrockii*. Both flower from July to August, and average 9–12 ins. high.

[1] E.g. *Botany for Beginners* (Stanford), or *Oliver's Lessons in Elementary Botany* (Macmillan).

BOUVARDIA (JASMINE PLANT. Nat. Ord. Rubiaceæ).—This is a beautiful evergreen flowering shrub and is most useful for furnishing a supply of flowers from September to January. It is propagated by cuttings of young shoots in heat, in March and April, inserted in a light fibry loam, leaf-mould and sand. Temperature needed 45–55° F.

Greenhouse Species and Varieties.—*Bouvardia Alfred Neuner.*—Double white. Flowers from September to January. Height, 1–1½ ft.

B. Bridal Wreath. — White. Flowers from September to January. Height, 1–1½ ft.

B. Humboldtii corymbiflora. — White. Flowers from September to January. Height, 1–1½ ft.

B. King of Scarlets.—Scarlet. Flowers from September to January. Height, 1–1½ ft.

B. President Cleveland. — Vivid scarlet. Flowers from September to January. Height, 1–1½ ft.

B. Priory Beauty.—Delicate rose. Flowers from September to January. Height, 1–1½ ft.

B. Vreelandii. — Pure white. Flowers from September to January. Height, 1–1½ ft.

BOX. — The genus BUXUS. See *SHRUBS.*

BOX ELDER (*Acer Negundo*).— See *TREES.*

BOX THORN (*Lycium chinense*).— See *CLIMBING AND TRAILING PLANTS.*

BOXES, CAPACITY OF. — See CAPACITY OF TANKS OR BOXES under VOLUMES in *ARITHMETIC AND GARDENING.*

BOYKINIA ACONITIFOLIA. — A name given to *Saxifraga aconitifolia*, which see in *SAXIFRAGA.*

BRACHYPODIUM (FALSE BROME-GRASS. Nat Ord. Gramineæ).— This is a genus of weeds the value of which for garden decoration is *nil.*

BRAMBLE.—See the genus RUBUS in *SHRUBS.*

BRAMBLES AND BERRIES.

Since the introduction of airtight preserving bottles these have come to the front, and are most useful in winter.

The WILD BRITISH BLACKBERRY repays for liberal treatment, but the most productive is the PARSLEY-LEAVED BLACKBERRY with big fruits. The LOGANBERRY also is splendid for jam or bottling and grows with great luxuriance. It resembles a giant raspberry but comes off with a core like a blackberry. We do not find the variety *Phenomenal* any improvement, and of several novelties we cannot at present give an opinion.

Culture is simple. After fruiting, merely cut away the old fruiting rods and train the new growths 2 ft. apart right and left on stakes to ripen the wood. This ensures a good crop the following season.

G. B.

[Other berries of easy culture are the HAILSHAMBERRY, the KINGS-ACREBERRY, the LAXTONBERRY, the LOWBERRY, and the WINEBERRY.—EDITOR.]

BRANDY BOTTLE (*Nuphar luteum*).— See *YELLOW WATER LILY.*

BRASILLETO. — A name applied to the genus CAESALPINIA. See *SHRUBS.*

BRASSAVOLA.—See *ORCHIDS.*

BRASSIA.—See *ORCHIDS.*

BRASSICA (Nat. Ord. Cruciferæ).

This is a large genus of hardy and half-hardy annuals and hardy or half-hardy biennials, including cabbages and greens in all their classes. It would be useless to give a list here of the various vegetables under their Latin names, as an article on each vegetable headed with its well-known English name, followed by the botanical one, appears in its proper place. Nor

shall we enlarge here on the general culture of the genus, for that too would be wasted space, since full details of the culture of each of these vegetables is given in each separate article.

See also under MUSTARD in *MEDICINAL HERBS*, and paragraph on MUSTARD AND CRESS in *SALAD PLANTS*.

BRASSICA FAMILY. — See *KINDS OF CROPS*.

BRASSOCATTLEYA.—See *ORCHIDS*.

BRASSOLÆLIA.—See *ORCHIDS*.

BRASSOLÆLIOCATTLEYA. — See *ORCHIDS*.

BRAVOA (Nat. Ord. Amaryllidaceæ).—This is a genus of half-hardy bulbs, the outdoor culture of which is only possible in the warmest of districts, greenhouse treatment giving the best results elsewhere. Light rich soil with plenty of rotted leaf-mould suits them admirably. *B. geminiflora* is the best known species, and bears red flowers in July and August on plants about 12 ins. high.—E.

BRAZIL NUT.—See *NUT CULTURE*.

BREVOORTIA (Nat. Ord. Liliaceæ). Only one species of this hardy bulbous plant is at all generally grown. This, *B. Ida-Maia* (Syn. *B. coccinea*, and *Brodiaea coccinea*), is popularly known as the CRIMSON SATIN FLOWER. It may be had in yellow, red, and dark crimson forms, and blooms from June onwards, growing 1–1½ ft. in height. Its general cultured requirements are the same as those of *BRODIAEA*, which see.—J. J. & E.

BRIANÇON APRICOT (*Prunus brigantiaca*).—See *TREES*.

BRIDAL WREATH.—See *FRANCOA*.

BRIGHT YELLOW CLEMATIS (*Clematis tangutica*, or *C. orientalis tangutica*).—See *CLIMBING AND TRAILING PLANTS*.

BRISTLY FOXTAIL GRASS. — See *SETARIA*.

BRITISH MYRRH PLANT. — See *SWEET CICELY*.

BRITISH WILD LILY OF THE VALLEY (*Convallaria majalis*).—See *LILY OF THE VALLEY*.

BRITTLE BLADDER FERN.—(*Cystopteris fragilis*).—See *FERNS AND FERN GARDENING*.

BRIZA (QUAKING GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy ornamental grasses useful for garden decoration and of very easy culture. The two best species are described in our article on *ORNAMENTAL GRASSES*.

BROAD BEANS. — See *BEANS* and *VICIA*.

BROAD BUCKLER FERN (*Nephrodium spinulosum dilatatum*).—See *FERNS AND FERN GARDENING*.

BROAD-LEAVED EVERLASTING PEA (*Lathyrus latifolius*). — See *CLIMBING AND TRAILING PLANTS*.

BROAD-LEAVED PARADISE STOCK. See under STOCKS USED in *FRUIT CULTURE : HARDY*.

BROCCOLI (*Brassica oleracea botrytis asparagoides*. Nat. Ord. Cruciferæ).—Few vegetables are more widely appreciated than this, and so it is important to maintain a succession as long as possible. Great attention should be paid to the selection of varieties, also the date of sowing, since it is only by this means that good heads can be cut from October until June.

Culture. — In common with all other plants of this tribe, good results need only be expected on ground which has been liberally treated with rich manure. Whenever possible, prepare the site as early in spring as circumstances allow; or where the local conditions are such as compel this crop to follow one of another kind the same season, endeavour to make the ground so firm either by rolling or trampling it, that planting is only possible with considerable difficulty.

Unless the site is made solid, the

strong sturdy growth so essential to plants which are to pass through an ordinary winter unharmed will not be forthcoming. A good firm root-run induces a slow but very hard growth, and plants grown under these conditions are much less susceptible to damage from severe frost, than others which during a warm autumn make tremendously large leaves and stems, but fail to give the heart the necessary protection even against the earliest winter frost. In addition to a firm soil, plenty of room between the plants is of utmost importance, this being equally as essential while they are still in the seed-bed, as when they are put out into their permanent quarters. A few weeks in an overcrowded condition during the first stages of growth may so ruin the constitution of the plants as to handicap them severely the whole season.

The seed-bed should always be made in good open quarters away from the shade of trees or buildings. When preparing it use air-slaked lime or soot freely to deter the attacks of many insect pests. Where an extra long succession of good heads is needed, make a start early in March. To follow these sow again in April. The main sowing of late varieties may be deferred until the first week in May. This last section boasts of a large number of good sorts, and is of such great importance that where only a few score or so are required, selection from this is most advisable, for if sown thinly at the period mentioned and good cultivation observed, the heads will be ready for use just when other fresh vegetables are most scarce.

Before the plants get crowded in the seed-bed, or as soon as the second pair of leaves are formed, carefully lift a good number of the most promising, with a small fork and replant in rows about 6–8 ins. apart, allowing the same distance between the plants. If this is done at the stage mentioned, every plant will make new roots at once, and later on may be lifted with a good ball of earth full of fibres, which enable it to be transplanted without a check. Those put out direct from overcrowded beds, which plants have very little root, will be very different. These in an unfavourable summer fail to make good growth for many weeks. Where the garden is an exposed one, or the soil very light, instead of following the usual plan by planting in the flat ground, it will be an advantage to plant in deep drills drawn out with the hoe; this will allow water being given to the plants without any waste, and also enable the grower, where the garden is exposed to strong easterly gales, to draw additional soil to the stems of the plants early in the autumn, thus securing them against damage from wind, and later from frost. This precaution has saved many plants when others growing in the same district have been ruined. When planting allow about 2–3 ft. between the rows, and not less than 2 ft. between the plants which are to stand the winter, the early sorts needing a trifle less.

Good Varieties.—*For Early Use.*—Grange's White Cape, Michaelmas White, Self-Protecting.

To Succeed These.—Backhouse's Winter White, Favourite, Osborne's Winter White, Snow's Winter, Vanguard.

For Spring and Summer.—Eastertide, Late Queen, Methuen's June Model, Reading Giant, Wilcove's Superb White,—F. R. C.

NEW VARIETY.

Whitsuntide.—This has very large, firm white heads. It is very hardy, and comes into use in June.

BRODIAEA (Missouri Hyacinth. Nat. Ord. Liliaceæ).—A race of pretty bulbous plants native to the Argentine, Brazil, and California, flowering as a rule in June and July. They are very varied in their habit, now that *Milla*, *Triteleia*, and other genera are included in the genus *Brodiaea*.

Culture.—This is easy, if a rich light well-drained soil and a sunny position are available. The bulbs should be planted either in September or October, and once well established they may be left undisturbed for several years, when they will quickly increase. Annual lifting is quite unnecessary. Nothing is gained by it unless an increase of any special varieties is wanted.

Brodiaeas may be successfully grown in 5-inch pots in light loam mixed with leaf-mould and sand. Plant the bulbs an inch apart each way, finishing potting by the end of October. Plenty of water is necessary while they are in active growth. The smaller species or varieties may be planted on rockwork and carpeted with some low growing plant.

What to Grow.—*Brodiaea californica* has umbels of deep purple flowers, and blooms in June. Its height is 1½ ft.

B. coccinea (Syn. *Brevoortia Ida-Maia*). See article on *Brevoortia*.

B. grandiflora is a blue-purple. It flowers in June. Height, 1½ ft.

B. Howelli lilacina produces pale blue or lilac flowers in July. Height, 1½–2 ft.

B. ixioides splendens (Syns. *Milla ixioides* and *Calliprora lutea*).—This variety has soft yellow flowers borne in umbels in early June, on plants 9 ins. high.

B. laxa (Syn. *Milla laxa*).—This bears numerous rich purple flowers in large umbels in June, and is 1–2 ft. high.

B. peduncularis (Syn. *Triteleia peduncularis*).—This is similar to *B. laxa* in growth, and bears porcelain coloured flowers in June, on plants 12 ins. high.

B. uniflora (Syn. *Milla uniflora*).—This is a charming rock plant. It produces a wealth of pale lilac-blue flowers in April and May. Its height ranges from 6–9 ins.—J. J. & E.

BROMPTON STOCKS.—See *Stocks*.

BROMUS BRIZAEFORMIS (Nat. Ord. Gramineæ).—The genus Bromus includes about forty annual, biennial, and perennial species of grasses, of which this is one of the most ornamental. Seeds should be sown in clumps or lines where the plants are to grow, in April or May (the resulting plants being thinned out to 6 ins. apart). Any good well-drained garden soil, in a sunny or open position, will be suitable. The stems may be cut, when in bloom, for mixing with cut flowers or to dry for home decoration in winter. The average height is 18 ins.—J. F.

See also *Ornamental Grasses*.

BROOM.—A name applied to the genus Cytisus, which see in *Shrubs*.

BROOMS.—See *Garden Tools*.

BROUGHTONIA.—See *Orchids*.

BROUSSONETIA.—For the best species see *Trees*.

BROWALLIA (Nat. Ord. Solanaceæ).—The perennial shrubby species of this genus are only used to a very limited extent out of doors and in the greenhouse, so we need not describe them here. Two annual species, however, are worthy of note.

Browallia demissa (Syns. *B. elata*, *B. lactea*, *B. linnaeana*, and *B. nervosa*) is a bushy sort bearing clusters of violet-blue flowers in August and September, and 9–15 ins. high.

B. grandiflora bears light yellow flowers from June onwards, and grows 2 ft. high.

Both sorts are best treated as half-hardy annuals, raising seedlings in gentle heat, potting them singly, in light soil, and growing them in the greenhouse or frame till planting out time in June. *B. demissa* is a capital pot plant for conservatory decoration or for grouping.

BRUGMANSIA.—A synonym for *DATURA,* which see.

BRUSSELS SPROUTS (*Brassica oleracea bullata gemmifera.* Nat. Ord. Cruciferæ).—Among winter vegetables none enjoy greater popularity than these, and although to the ordinary man who purchases his supplies from the greengrocer there may appear to be little or no difference between varieties, experienced growers know full well the suitability or otherwise of particular sorts for their own soils. Some of the more recent additions to these show a great improvement over earlier introductions, many of these combining superior table quality with increased productive powers, the aim of present-day raisers being to secure plump solid sprouts together with increased hardiness, rather than large size, which at many tables is not a recommendation.

Culture.—These may be termed the gluttons of the vegetable garden, it being impossible to produce plants any way approaching in size or appearance those usually found in tradesmen's seed lists without adding plenty of rich humic stable or cow-manure to the soil. Artificial fertilisers are not efficient substitutes.

Next to the manure, failure to provide adequate space between the plants for the development of the huge heads has an important bearing on the crop, and other conditions being right, is directly to blame for small crops of poor quality. Even where space is very limited, the idea of attempting to grow two plants where there is only sufficient room for the proper development of one, should not be encouraged, for, generally speaking, the result of this short-sighted policy is a lighter crop and sprouts of inferior quality than would have followed the planting of half the number.

For very early gathering it is usual to sow a little seed under glass early in February, and by successive prickings out, or potting on, we obtain strong plants about 9–12 ins. high, ready for planting out by 30th April. Such plants, if very liberally treated when in their summer quarters, usually give good firm sprouts during August; but a sowing made on a well-prepared bed in the open border any time after the 1st of April may be depended upon to give an abundant crop of sprouts from October to January. A later sowing made between 1st and 21st May, if carefully treated as regards watering during early growth, will carry on the supply until the end of March. Sow the seed very sparingly in every case, and far better than the popular plan of sowing in narrow drills, let them be about 3 ins. wide, and not less than 9 ins. apart, covering the seed with about an inch of fine soil.

If no preliminary transplanting to temporary beds can be undertaken, as soon as the seedlings are a few inches above the ground, reduce the number to allow each to stand

at least 2 ins. from its neighbour, but whenever possible temporary transplanting to 9 ins. apart each way is advisable, for if the bed these are to occupy for a few weeks is enriched with a little old hotbed manure, or well-decayed leaf-soil, and a minimum of 9 ins. each way allowed between the plants, they will take no harm even though left until the end of July. The large number of fibrous roots each plant will then carry will enable it to pass through that usually very trying period without injury. Use a garden trowel when planting out, and follow immediately by a thorough watering. The distance between the rows should never be less than 2½ ft.; 6 ins. more where the ground is exceptionally well manured. Two feet between the plants will be ample for most varieties mentioned below, the last three giving good sprouts at 18 ins.

Although well able to withstand an ordinary English winter, when frost is particularly severe or prolonged, these, in common with most other hardy greens, fail to pass unscathed. For this reason, should indications be apparent that the thermometer is going to fall unduly low, the lifting and safe housing of a dozen or so of the best plants is advisable.

The heads of the plants together with the large leaves should be permitted to remain on the plants until the last of the sprouts are gathered, when they may be cut off and used as a cabbage.

Varieties. — Among the many sterling varieties now offered by leading firms, the following are recommended:—Sutton's Exhibition, Matchless, Solidity, The Wroxton, Cambridgeshire Champion, President Carnot, Sutton's Dwarf Gem, Scrymger's Giant, The Bullet, Veitch's Paragon.—F. R. C.

BRYANTHUS.—For the best species see *SHRUBS*.

BRYOBIA.— See RED SPIDERS in *INSECT PESTS*.

BRYONIA (BRYONY. Nat. Ord. Cucurbitaceæ).—This is a genus of weedy plants of no garden value whatever, though in the old days some species were esteemed on account of medicinal virtues. The best known sort is *B. dioica* popularly called DEVIL'S TURNIP on account, no doubt, of its violent purgative properties. It is an ornamental climber for rough places.

BRYONY.—See *BRYONIA*.

BUBON.— Now included in the genus *SESELI*.

BUCK BEAN. — See *MEDICINAL HERBS* and *MENYANTHES*.

BUCK-WHEAT (*Fagopyrum esculentum*).—See *FAGOPYRUM*.

BUCKLER FERN. — The various forms of this are referred to under NEPHRODIUM in *FERNS AND FERN GARDENING*.

BULB PLANTING.

A few hints on this all-important subject are given below.

Where there are to be Wallflowers with Double Arabis as an edging, Daffodils may be planted between the lines of Wallflowers, and the effect will be very fine indeed, especially if the Wallflower be blood-red. May-flowering Tulips should on no account be planted in amongst Wallflowers, but in a bed to themselves, or in a bed on which Forget-me-nots are planted. Aconites, Crocuses, Grape Hyacinths, Snowdrops, and others may be used for edging instead of Double Arabis, but they are soon over.

Hyacinths should not be wasted among Wallflowers. If a rather long bed is to be filled, have a double row of tall Daffodils at the back, then a row of May-flowering Tulips, in front of this a row, or, better still, a double row of bedding Hyacinths, and lastly in front of this an edging of Crocuses and Snowdrops. This bed will be a lasting joy.

You should certainly have at least one small bed filled with Hyacinths only, just edged with Crocuses; but with regard to the Tulips, a better effect is produced to my mind if the colours are kept separate. (Hyacinths are seldom abundant enough to allow this.) Have a bed of dark red Tulips, then two of white and one of yellow if the beds are in a line. Single Arabis may be used for covering the soil of the bed.

If you have separate beds to devote to Daffodils do not fill these with bulbs the names of which you are not sure of. Get named varieties for these beds, such as Emperor, Mme. de Graaff, Empress, and Horsfieldi. Daffodils may well be planted in beds alone, but excellent effects are produced if they are planted in circles, and surrounded by a circle of early Tulips such as Duc van Thol or Pottebakker.

So much for suggestions as to how to get pleasing effects. Now let me give a few cultural details, for it is these that will be very useful.

The Planting of Bulbs.—Outdoor bulbs should be planted preferably in good time in October, but at any rate got in by All Saints' Day. The soil if heavy should be lightened by digging in some sand, and should be enriched if poor by adding some old hotbed manure. This, however, must be buried *deeply*.

The bulbs need not be planted with a trowel (except in the case of Hyacinths), but with a large unpointed dibber. The haft of an old spade is excellent for this purpose. A piece of wood should be tacked on to the dibber transversely, so that the dibber may be put in a uniform depth. The soil must be broken up and made friable so that this can be done easily.

About the Depth to Plant.—The following have been well tried and are considered the best:—Crocuses 3 ins., Daffodils 4 ins., Hyacinths 4 ins., Tulips 5 ins., Winter Aconites 3 ins., Snowdrops 3 ins., Scillas 4 ins. Any other bulbs may be safely planted three times their own depth in soil.

As regards the distance apart to plant, this should average 6–9 ins. with the bigger bulbs. Clumps of Crocuses and Snowdrops may also be 6 ins. apart.

Final Remarks.—It may be well before concluding to give one or two final remarks and then sum up.

The biggest point which makes for success is to get good bulbs. *Never* buy cheap collections of bulbs, but go to a good bulb man, and pay a fair price.

See the bulbs before you buy them, and buy as soon as possible after August. Good bulbs have a firm feeling about them.

Don't buy bulbs at auction sales or from firms who advertise flagrantly.

Don't try to plant various sorts of bulbs in geometrical figures unless you have a good knowledge of Geometry. A figure that has "not quite come off" is a hideous eyesore. Keep to squares and easy curves in this form of planting. These are not hard to get fairly accurate.

To sum up the main cultural points, I may say: Give a good well-worked soil with sand in it: Plant as early as conveniently possible: Plant with a large unpointed dibber, not too deeply, and plant bulbs of each genus uniform depths: Make moderately firm after filling in the holes; and give each bulb room enough in the bed for it to develop.—E.

BULBOCASTANUM.—Now included in the genus *CARUM*.

BULBOCODIUM (Nat. Ord. Liliaceæ).—Only one species of this hardy Crocus-like bulb is at all generally grown. This, *Bulbocodium vernum* (Syn. *B. ruthenicum*), popularly known as the SPRING MEADOW SAFFRON, and its variety *versicolor*, bear purple flowers in February and March, on plants 3–6 ins. high. Only the simplest culture is required, the bulbs being planted in the autumn in the usual way.

BULBOPHYLLUM.—See *ORCHIDS*.

BULBOUS BEE PLANTS.—See *BEE PLANTS: LISTS OF*.

BULBOUS CROPS.—See *KINDS OF CROPS*.

BULBOUS IRISES.—See *IRISES*.

BULBOUS PLANTS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING*.

BULBOUS PLANTS FOR CONSERVATORIES.—See *CONSERVATORY*.

BULBS AND BULBOUS PLANTS.—Notes on these appear mostly under their English names throughout the work.

BULBS: CLEANING AND STORING.

Amateurs often regard bulbs which have been grown in the borders for a season or two as useless for further planting, and consequently throw them away. This is very wasteful, and, indeed, it is running some risk even to leave bulbs in borders for two seasons if such borders are to be "bedded out." In both cases it would be better to lift, clean, and store as soon as the bulbs have finished flowering.

Drying-off Bulbs.—There are various ways of doing this. Some gardeners lift the bulbs and lay them in for a time in a north border for the growth to wither away; then they lift them again and dry prior to storing. As a matter of fact it appears to be rather a waste of time to lift, replant, and then lift again. The better plan is to lift the bulbs and merely to shake the soil from their roots, cutting no leaves or roots off, and then to lay them out in a single layer on a sunny path or sloping bank to dry, turning them over from time to time to ensure every part reaching the sunlight. It is better not to put them into boxes and to stand the boxes outside, since during wet weather it may happen that the wood of such boxes swells, and then the boxes will hold water, causing the bulbs to rot off instead of to dry. When thoroughly dry the leaves will have withered away and become brittle and brown, the bulbs themselves will be hard, but the outer

skins will be soft and papery. The roots will mostly be like thin greyish bits of string; they will be shrivelled up and lifeless.

Cleaning.—This is an important matter. First of all the withered tops should be pulled away from the top of the bulb, and the withered roots clipped off with secateurs or shears. Each bulb should then be worked between the hands to remove soil and loose outer skin, and any broken pieces still adhering may be gently pulled off. Great care must be taken not to *peel* the bulbs, as otherwise they will not keep long; only the skin which is loose and has been in direct contact with the soil should come off. Usually below this outer skin little bulbils will be found clustering round the parent. The largest of these may be saved and replanted in nursery beds, the rest being destroyed.

Storing.—Bulbs are not difficult to store, since they only have to be out of the soil during the drier part of the year, namely, in the summer. So long as a cool dry place is available they should store perfectly after being well dried. Barrels can be used for the larger bulbs, such as daffodils and hyacinths, while brown sugar bags will serve the purpose admirably for the smaller bulbs. Darkness is not, of course, absolutely essential for the successful storing of bulbs, but, generally speaking, it is usually considered best to keep the light from them in the summer months.—E.

BULLACES. — See *DAMSONS AND BULLACES,* where a selection of varieties of these is given.

BULLEY'S PRIMROSE (*Primula bulleyana*).—See *PRIMULA.*

BULRUSH (*Scirpus lacustris*). — See *SCIRPUS.*

BUNCH GREENS.—A popular name for *COLEWORT,* which see.

BUNIUM.—Now included in the genus *CARUM.*

BUPHTHALMUM (Nat. Ord. Compositæ).—This genus is little known but might well be grown more often than it is. Readers will remember the INULA. This plant is not unlike it.

Culture.—This is easy. Any good garden soil seems to suit the hardy perennial species; and they will succeed in a border fully exposed to the sun. With the half-hardy sorts we need not trouble the reader. Propagation is not difficult; it may be effected by splitting up the old roots in the autumn or spring, or by sowing seeds in the usual way. The planting may be done in November, February, or March.

What to Grow.—The following may be included if space permits:—

Buphthalmum cordifolium.—A synonym of *B. speciosum,* which see.

B. grandiflorum.—A synonym of *B. salicifolium grandiflorum,* which see.

B. salicifolium grandiflorum (Syn. *B. grandiflorum*).—A useful large yellow-flowered species blooming from June to September and averaging half a yard in height.

B. speciosissimum.—A yellow-flowering sort blooming in June and July, but a little taller than the last named.

B. speciosum (Syn. *B. cordifolium*). —A tall yellow mid-summer blooming sort attaining a height of nearly 2 yds.—E.

BUPLEURUM.— For the best species see *SHRUBS*.

BUR CHERVIL (*Anthriscus vulgaris*). See *ANTHRISCUS*.

BURDOCK. — See *ARCTIUM* and *MEDICINAL HERBS*.

BURGUNDY MIXTURE.—See *SPRAYING MIXTURES AND FUNGICIDES*.

BURNET.—See *POTERIUM*.

BURNET ROSE (*Rosa spinosissima*).— See *ROSE SPECIES*.

BURNING BUSH (*Dictamnus albus purpureus*).—See *FRAXINELLA*.

BURNING BUSH (*Euonymus atropurpureus*). — See *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

BURNING GARDEN RUBBISH.

In the article on *VEGETABLE MATTER* we praise the plan of allowing green garden refuse of a soft and clean nature to decompose into manure. We mention, however, that certain kinds of rubbish are undesirable for the purpose of making into manure, and we advise that they should be burnt in the way described in the present article.

Before describing the various ways of burning garden rubbish, it may be useful to give a list of the more common forms of rubbish which should be burnt, since it is easy for gardeners who have not had many years of experience to mistake as good material for making into manure, rubbish which is not only valueless but may prove very dangerous indeed if put to this purpose. Gardeners might do well to commit the list to memory, and then they will recall it when working out of doors.

First of all we must place on the list any and every form of wood. There are wood chippings which are often abundant when new fencing is being put up, or old repaired; there are twigs which are so abundant when there has been a stormy week; and there are woody trimmings from climbers, fruit trees, hedges, roses, and shrubs. All these are not the least use for making into vegetable manure.

Next come certain kinds of leaves. As a general rule most kinds of shrub leaves are undesirable for rotting down into humus. Of tree leaves, ash, elm, holly, horse-chestnut, ivy, plane, poplar, privet, sycamore, and indeed other sorts as well are little use for vegetable humus, so should be burnt. With them must go the droppings or needles from pines and other coniferous trees. These last are extremely detrimental if dug into the soil, and even to use them as a mulch, which one sees recommended so often, is undesirable in our opinion, since the resinous and oily matter they contain is abhorred by nearly every variety of plant.

After these we come to weeds. Now the "pen gardener"—a gentleman for whom we have considerable contempt—says to us in his books and articles: "Burn up every weed which grows in the garden and spread the ashes on the soil."

But as we see in another article if this doctrine is acted upon we often waste much which might be turned to good account in the way of humus. So for burning we should avoid the softer rottable kinds of weeds with very few exceptions. All deep rooting weeds (if we cannot sell them to herbalists) should go to our garden fire, also all creeping weeds. One gentleman was preaching [1] the stacking of twitch and other equally dangerous weeds such as coltsfoot, dandelions, and docks, in large heaps for a year, after which "they can be spread on the land and make most valuable manure." This gentleman, who was by many considered to be an authority, ought to know better than to give such very bad advice. Twitch will

[1] At a lecture attended by the writer in South Yorkshire.

not all be dead even after stacking for thirty months, and to spread it on the land after a single year is to undo all the good you have done the previous year. The only safe place for twitch and other violent weeds is in the garden fire.

There are some weeds which may look innocent enough but are really great dangers. These include chickweed and other similar plants. Thus discrimination is necessary and the gardener should put these sorts also on the fire.

All weeds in seed should also be put on the fire. The idea that the small heat produced by rotting will kill the seeds is entirely erroneous; very often it proves an apt method of forcing them into brisker germination.

After weeds, we come to vegetable garden refuse. Now the material which should be burnt here includes a very wide selection. We suppose that potato tops with their fibrous roots should be put first in the list, for they should never be allowed to rot into manure. A good second place is taken by stumps of cabbages, cauliflowers, Brussels sprouts, and the like, which will, it is true, make fairly good vegetable manure if allowed to rot for a period of something like two and a half years. As these emit an impossibly offensive odour, and breed billions of flies during the process, it is better to get them burnt up. We must also mention asparagus foliage obtained often in cartloads when the beds are cleaned in the autumn. No good purpose can be served by allowing this to decompose into vegetable humus.

Of miscellaneous refuse from the vegetable garden which ought most certainly to be burnt we may mention any foliage or roots of plants which are in any way diseased, however slightly. Potato-tops have been mentioned; burning of these is in any case desirable, as we have said, but it is essential if they are diseased. But burning is, in the case of turnip-tops, beet-tops, parsnip-tops, carrot-tops, pea and bean haulm, cabbage leaves, onion and leek foliage, and so on, only desirable when such matter is infested with pests, or infected with diseases. Otherwise it should be allowed to decay, as described in another article.

Of miscellaneous refuse from the flower garden which should be burnt we may mention first any foliage of plants which is distinctly hard or woody in character, as, for instance, the thick stems of full-grown hollyhocks and sunflowers, or the thin wiry stalks of chrysanthemums or Michaelmas daisies. Other plant remains (provided, of course, that they are not carrying diseases or pests) should certainly be allowed to rot. It may be said here, however, that any seed heads on these plant remains should go into the fire, for the seeds will germinate and little plants come up all over the borders from the manure unless burning is done.

Methods of Burning.—The first and most obvious method of burning garden rubbish is to do the work in an open fire. The fire is started with a little wood and paper and then the driest rubbish put on first. Dense clouds of brown or often orange-coloured smoke intermixed with flames are emitted, and the whole heap is reduced to about a twentieth of its original bulk if not less. This is a wasteful way of destroying refuse and one which should not be allowed.

A better method is to start with a very small fire, and see that it never becomes a mass of dancing tongues of flame even for a moment. This is done by piling damp rubbish

on to the fire at an early stage and reducing the burning to a smoulder. Rubbish burnt this way is on the fire longer, but the ash produced is much more bulky as well as far more rich in plant-food than is that produced on a roaring fire. Besides this, the burning on what is called a "smother" fire is much less unpleasant. Instead of the dense clouds and thick volumes of smoke produced by the "quick fire" method, there is only a small curling column of smoke which annoys no one.

If the rubbish has for some reason or other had to be neglected and has got into a soaking wet state it will not burn at all easily. An acquaintance who is on the Board of Agriculture tells us that he uses a bucket with a number of holes all round it for burning wet rubbish, and starts a small coal fire in it, putting on the rubbish in small forkfuls first of all, and then in larger quantities when a good mass of red-hot ash has been produced below. He says he never finds this fail as a means of disposing of wet refuse.

Another authority speaks well of a brick kiln made by building a circular cupola with bricks after breaking off their corners. We have tried this method and find it works well so long as plenty of air-holes are left all round. A small fire is started in the bottom, and the rubbish fed in, a small quantity at a time, from the top. It needs pushing down from time to time unless the opening at the top is very large to admit of natural sinking. The ashes are, of course, raked out from one of the holes at the base.

Store the ashes produced by burning garden rubbish in a dry place, for they are quickly ruined by rain. Do not leave them in the destructor, for moisture will soak up from the ground below.—E.

BUSH FRUITS.

Bush fruits, as is generally understood by the term, consist of the Gooseberry (*Ribes Grossularia*); Red Currant (*Ribes rubrum*); White Currant (*Ribes rubrum album*); Black Currant (*Ribes nigrum*); summer and autumn fruiting Raspberries (*Rubus Idaeus*), and the Loganberry (an American hybrid).

With perhaps the exception of the last named, all are very popular and extensively grown, the demand for the fruit while it is in season being very great. The Loganberry is cultivated principally in private gardens for the sake of the variety which its fruit affords.

All are of hardy constitution, easily cultivated, and succeed in all parts of the United Kingdom where soil and climatic conditions are favourable. They are extremely productive and the produce is put to many and diverse uses, such as the making of tarts, preserving, bottling, for dessert and even for medicinal purposes.

The Gooseberry is first ready for use, as the fruit possesses the good quality of being fit for consumption both in a green as well as in a ripe condition. The early large fruiting varieties are those generally grown

to afford fruit in the first-mentioned state, as the berries attain a profitable size in advance of the early medium and small fruiting kinds. It is, however, among the latter, irrespective of season or period of ripening, that the majority of the highly-flavoured luscious sorts are found, and in many instances they are grown apart from the former so that they can be netted in and rendered immune from bird attacks.

Red, White, and Black Currants reach maturity before the Gooseberry, and, like the last, are, with the exception of the White Currant, in such great demand that the crops prove highly remunerative. Of the four, the Gooseberry is perhaps, from a commercial as well as a private point of view, the most valuable. The white variety is grown to a much more limited extent, and the fruit is, beyond dessert purposes, employed principally for mixing with the red kinds for clarifying in the making of jelly.

The cultural treatment necessary for the Gooseberry being similar to that required for the Red, White, and Black Currant, it is unnecessary to deal with each under separate headings. All are extensively cultivated in the form of bushes, but the Gooseberry, Red and White Currants are also now much grown as espaliers and as two, three, and five branched cordons for training on trellises in the open, against fences and outbuildings, and on garden walls having a north aspect, by which means the supply is, in the last-named instance, considerably prolonged. They are also in a few cases grown in the form of standards, the stems being about 4 ft. in height.

Bush trees are generally planted 4½–5 ft. apart in the rows, with a distance of 6 ft. between them. Two, three, and five branched cordons, 2 ft., 3 ft., and 5 ft. respectively, and standards 6–8 ft. apart when employed, as is generally the case, as ornamental specimens in borders on either side of a frequented footpath. Espaliers may stand 9 ft. apart from each other.

Bushes are usually, although not always, planted in breaks varying in number from a few dozens to several hundreds, according to the demand for the fruit.

The kind of soil best suited to the needs of the Gooseberry, Red, White, and Black Currants, is in the first three-named instances a rich well-drained loamy medium, and in the last case one of a moister or more retentive nature, but with care in preparation, such as in deeply digging and manuring on a liberal scale, most kinds of soils can be rendered suitable. Not only is it necessary to enrich the soil before planting to ensure vigorous growth, but manure in some form or other must, after the bushes are established and come into bearing, be afforded each year afterwards to maintain their fertility. This should be applied to the surface on the completion of pruning, and be buried or dug in just beneath the surface.

With the exception of the Black Currant, all should be accorded a light open position. The species just mentioned prefers and yields the heaviest crops when grown in a semi-shaded position or the coolest part of the garden, such as in the vicinity of a north wall or hedge.

The fruit is produced in the case of the Gooseberry on spurs and young wood of the previous season's growth, on spurs in regard to Red and White Currants, and on the strong young wood with respect to the Black Currant. The three first should have clean stems standing not less than 1 ft. above the soil level, so that the fruit may not be

spoilt by being splashed with soil during rainstorms, while the last should be allowed to branch out freely from the base, and produce vigorous growths annually. In the essentials named it is seen that the cultivation of the Black Currant differs somewhat from that of other fruits under consideration.

Propagation is invariably effected by means of cuttings made from straight stout well-ripened shoots of the current season's production, selected at the time of pruning. These may be from 18–24 ins. in length, and, with the exception of those of the Black Currant, all buds except four or five at the tips should be removed from the cuttings to ensure clean stems and to avoid risk of suckers being pushed up from the base. As the last-named propensity is to be encouraged in the Black Currant, the removal of the buds in this instance is undesirable. The base of the cuttings should be cut close to a joint, and the tops shortened back if the wood is weak or in an immature condition. Autumn or early winter is the best time to plant the cuttings. Set them 6 ins. deep, 9 ins. apart, in rows 1 ft. asunder, in soil which has been previously manured and well dug. Planting may be performed with a dibber, and the soil should be made quite firm round every cutting.

In some instances all five buds left on the cuttings—Black Currants excepted—will break, in others but two or three. The shoots which will eventually develop from these breaks should be cut back the following autumn to form the bases of the main branches in the case of trees intended for bushes. All should then be lifted and transplanted 2 ft. apart in rows standing 3 ft. asunder. During the next season enough growths will result to furnish the foundation of the future heads, and in the year following will develop sufficiently to allow of their being planted in their permanent positions. For culture as Cordons, see article on *Cordon Fruit Trees*.

To form Espaliers, take a tree having three shoots, train out the two lower ones horizontally and cut them back somewhat, leaving both of equal length. The third or central shoot should be trained upright, then cut it back, leaving it 1 ft. in length. The next year train out the leading shoots on the lowermost branches, cutting back all other growths to six leaves in July, and to three buds the following autumn. Train the leading growth on the central cut back shoot—which is now really a continuation of the stem—in an upright direction, and select two shoots immediately below it and train them out, one on either side at right angles to form another tier or pair of branches, continuing in this way each year until a sufficient number of branches has been secured. See also *Espalier Mode of Fruit Culture*.

The training as regards Cordons is best done with the aid of stakes. (Standards are usually formed by grafting scions of the Red and White Currant on single-stemmed plants of *Ribes aureum*.)

The Pruning, as regards established bushes of Red and White Currants, consists in cutting back all young shoots in summer or July to six leaves, and further shortening them to two or three buds in autumn or winter. Leave shoots intact where necessary for the filling of vacancies caused by accident or branches dying, and shorten them back in winter to where they are well ripened.

Black Currants need different treatment, the pruning being confined to thinning and cutting out as much of the old wood as possible,

to make room for that produced during the past and previous season as well as to induce the production of vigorous growth in future.

Gooseberries which are to supply fruit in a green state are spur-pruned, a certain amount of well-placed young shoots being left as well on the bushes, the latter being merely tipped. In all other cases the young wood is spurred back to two and three buds. Those varieties of which the growth is of a drooping nature should be pruned so that the branches are well off the ground. In regard to the dessert kinds, the trees should be spur-pruned and the branches disposed widely distant from each other so that gathering may be conveniently done. The pruning of full-grown cordons is performed in the same way, *i.e.*, partly shorten back side-shoots and spur growths in summer and spur in closely to two or three buds in winter. Leave shoots where required to make good losses or to eventually replace decrepit and worn-out branches.

The Raspberry succeeds best in an open position in well-manured deeply dug soil of a loamy nature, but with attention to preparation in the manner described and in applying manure annually after the canes come into bearing, most kinds of soil can be rendered suitable to their needs.

As regards the cultivation of the summer fruiting varieties, several methods are practised, but that which finds favour generally is to plant the stools 18–24 ins. apart in rows 6 ft. asunder, and to train the canes to a wire trellis. Very heavy crops of fruit result by pursuing this method. The trellis should be provided with three or four wires running transversely, and be about 5 ft. in height.

Propagation is best effected by the young canes or offsets which are pushed up in abundance in the vicinity of the old stools. Dig these up in autumn and transplant 1 ft. apart in rows 2 ft. asunder, for one season, or they may be permanently planted at once. The canes should be cut down to within 6 ins. of the soil in February. The following autumn thin out, if necessary, the canes produced during the summer, dispensing with the the weakest and retaining the strongest, tying them temporarily to the wires. The following February give them a final look over, cut off the tips, and on this occasion tie them securely to the trellis. Once the stools are established a great number of shoots or young canes will push up around the stools and between the rows. Of these enough should be left to furnish a supply of canes close to the stool for fruiting in the succeeding year, and cut or hoe off the surplus. After the crop has been gathered the old fruiting canes should be cut out and the new ones of the current season's growth thinned, leaving the best ripened, strongest, and a sufficient number, so that when finally tied to the trellis in February they will stand from 8–9 ins. apart. Until then they need only be provisionally tied in to prevent them from being blown about and broken by rough winds, as well as for the sake of appearance. The tipping or cutting back should be done some 5 ins. or 6 ins. above the topmost wire. Digging, if indulged in at all between the rows, must be very lightly done or only sufficiently to bury the dressing of manure spread over the surface in the previous autumn. In a great many instances the ground is never dug from the time planting takes place until the plantation is broken up.

The autumn fruiting varieties,

unlike the preceding, bear on the canes produced during the summer months, consequently these, after they have fruited, are cut down to within a few inches of the ground the following February. In due course new canes are pushed up, which, when sufficiently advanced in growth, are thinned out and tied to the trellis 9 ins. apart. They will fruit abundantly in the autumn, the fruit proving very acceptable for various purposes at this season of the year. In all other respects cultivation and propagation are the same as for the summer fruiting varieties.

Much the same treatment is necessary for the *Loganberry*, with the exception that being of a more rampant habit of growth the trellis should be not less than 6 ft. to 8 ft. in height, as the canes or growths, being so vigorous, often attain a length of 10 ft. to 12 ft. These canes should also be trained and tied more widely apart on the trellis.

SELECT LIST OF BUSH FRUITS.

Currants: *Red and White.*—La Constante, La Versaillaise, Raby Castle, Red Dutch, White Dutch Cut Leaved, White Transparent, White Versailles.

Black.—Baldwin's or Carter's Champion, Black Naples, Boskoop Giant, Lee's Prolific.

Gooseberries: *Large Red Varieties.*—*Crown Bob, Dan's Mistake, Lancashire Lad, Lord Derby, Speedwell, *Whinham's Industry.

Small Fruited Red Varieties.—*Ironmonger, Keen's Seedling, Red Champagne, Warrington.

Large White Varieties.—Careless, King of Trumps, Lady Leicester, *Lancer, Transparent, Whitesmith.

Small Fruited White Varieties.—Bright Venus, Cheshire Lass.

Large Green Varieties. — Stockwell, Telegraph, Thumper.

Small Green Fruited Varieties.—Glenton Green, Gretna Green, Langley Gage, Pitmaston Greengage.

Large Yellow Varieties.—Catherine, Criterion, Gunner, *Keepsake, Langley Beauty, Leader.

Small Fruited Yellow Varieties.—Champagne, Golden Drop, Golden Gem, Golden Lion.

Those against which an asterisk is placed are a few of the best to grow for gathering from while the fruit is green.

Raspberries: SUMMER FRUITING VARIETIES. — *Red.* — Baumforth's Seedling, Hornet, Norwich Wonder, Superlative.

Yellow.—Antwerp, Guinea, Queen of England.

AUTUMN FRUITING VARIETIES.—Belle de Fontenay, November Abundance, October Red, October Yellow.—A. W.

See also *KINDS OF CROPS.*

NEW VARIETIES.

Blackberry, Himalayan.[1]—A free-fruiting sort, bearing large panicles of good sized berries.

Raspberry, Lloyd George.—A perpetual fruiting variety, of good size and excellent flavour.

BUSH HONEYSUCKLE. — A name applied to the genus DIERVILLA. See *SHRUBS.*

BUSH VETCH (*Vicia sepium*).—See *VICIA.*

BUSHEL, WEIGHT OF.—See WEIGHT OF BUSHEL in *ARITHMETIC AND GARDENING.*

BUSHES, PRUNING OF.—See *PRUNING FRUIT TREES.*

BUTOMUS (Nat. Ord. Alismaceæ).

One species of this genus is well worth growing, namely, *B. umbellatus*, the FLOWERING RUSH, which bears pretty pink flowers in June, and averages half a yard in height. It is a hardy perennial aquatic, suitable for the wild or water garden, and once planted will look after itself.

BUTTER BEANS.—See DWARF WAX-POD, or BUTTER BEAN, in *BEANS.*

BUTTER BURR.—See *PETASITES.*

BUTTER DOCK (*Rumex obtusifolius*). See *RUMEX.*

BUTTER NUT.—See *NUT CULTURE.*

BUTTER-WORT.—See *PINGUICULA.*

[1] Probably a hybrid of continental origin. It does not come from the Himalayas.

BUTTERCUP.—See CREEPING BUTTERCUP in *WEEDS*.

BUTTERCUP OXALIS (*Oxalis cernua*). See *OXALIS*.

BUTTERFLY FLOWER.—See *SCHIZANTHUS*.

BUTTERFLY ORCHIS (*Habenaria bifolia chlorantha*).—See note at end of *HARDY ORCHIDS*.

BUTTON SNAKE-ROOT. — See *LIATRIS*.

BUTTON WOOD (*Platanus occidentalis*).—See *TREES*.

BUTTONHOLES, ROSES FOR.— See ROSES FOR BUTTONHOLES in *ROSES FOR ALL PURPOSES*.

BUXUS.—For the best species see *SHRUBS*.

BYE-LAWS *re* **FIXTURES.** — See *GARDENING LAW*.

BYTURUS.—See RASPBERRY MAGGOT or BEETLE in *INSECT PESTS*.

C

CABBAGE (*Brassica oleracea capitata*. Nat. Ord. Cruciferæ).—By making sowings at different periods, fully developed heads of cabbage of good quality may be had throughout our twelve calendar months. Fortunately, these useful plants thrive in almost any locality, and only in the event of a very prolonged and severe winter following a mild autumn, need much damage be expected from frost.

A greater diversity of size is found in these than in any other easily grown vegetable, fully grown hearts varying from an ordinary cocoa-nut to specimens over a yard across. The smallest varieties, in addition to being of much more rapid growth, are undoubtedly of superior table quality, and for this reason are recommended to those only having a small family to provide for. They will equally commend themselves to others who grow cabbage more particularly always to have a reserve to draw upon should a more important crop fail—an event quite likely to occur even in the best regulated gardens.

Culture.—Make the first outdoor sowing as early in March as the state of the ground allows, and, provided the variety sown is a suitable one, plants from this sowing will give firm hearts very early in July.

An April sowing of a larger variety should be at their best during the second week in August, while if plants from a sowing made about the middle of May are given good land and an open situation, excellent heads should be available throughout late autumn and the winter. Undoubtedly the heads produced in early spring are the most popular. These are obtained by sowing the seed of well-tried varieties in late July or early August of the previous year.

If seed is sown thinly, no pricking out or twice transplanting will be needed; but overcrowding in the seed-bed must be avoided, such having a very weakening effect upon the plants, and, of course, delaying the date of maturity of the hearts.

The best results are obtained by planting in heavily manured land, but quite good cabbage may be cut from plants put out after an earlier crop of something else has been taken without further manuring. In addition to being rich, the soil should also be made moderately firm, a loose, porous root-run favouring the production of extra large leaves and loose heads, which find but little favour with many cooks and growers.

When cutting the heads of these from plants of either sowing mentioned above, a little extra care should be taken always to leave a few large leaves on each stem. Then a good and continuous crop of side-shoots will push out and provide a most useful vegetable for many months afterwards.

The distance usually allowed be-

tween what are termed Spring Cabbage is 18 ins. from row to row and 15 ins. between the plants. The smaller growing varieties of these will, however, give good results if planted much more closely. Where the extra large varieties are grown for autumn use, 2 ft. each way will be quite little enough.

Varieties:—*For Early Sowing.*—All Heart, Beefheart, Defiance, Earliest of All, Harbinger, Imperial, Knight's Pointed Head, Mein's No. 1, Winningstadt.

For Spring Use. — April, April Queen, Early Offenham, Early York, Ellam's Early, Favourite, Flower of Spring, Harbinger, Manchester Market, Nonpareil.—F. R. C.

CABBAGE BLACK ROT.—See BLACK ROT OF CABBAGE in *DISEASES OF PLANTS.*

CABBAGE CATERPILLARS. — See under CABBAGE WHITE BUTTERFLIES in *INSECT PESTS.*

CABBAGE, CHINESE.—See *CHINESE CABBAGE.*

CABBAGE, CLUBROOT.—See CLUBROOT in *DISEASES OF PLANTS.*

CABBAGE LEAF AND STALK MINER. See *INSECT PESTS.*

CABBAGE MOTH.—See *INSECT PESTS.*

CABBAGE, RED or PICKLING.—See *RED CABBAGE.*

CABBAGE ROOT FLY.—See *INSECT PESTS.*

CABBAGE ROSES.—See under PROVENCE ROSES in *ROSE CLASSES.*

CABBAGE, SAVOY (*Brassica oleracea bullata major.* Nat. Ord. Cruciferæ).—This forms a very reliable winter crop, and, except during the most severe weather, it may be depended upon to withstand the winter better than most green crops.

Culture.—Seed may be sown from 15th March to 31st May. Similar treatment to ordinary cabbage will prove successful.

Cutting should not commence until November, a few slight frosts vastly improving the table quality.

Although it is usual to pull up the stem after the head is cut, in times of great scarcity of other greens this should be left in order that later shoots may push from the top. These form an acceptable vegetable. The small growing varieties mentioned here are of the best flavour, and should be grown by those having small gardens.

Varieties :—*Small.*—Dwarf Golden Globe, Early Ulm, Little Pixie, Sugar Loaf, Tom Thumb, Vienna Early.

Maincrop (*i.e.* large sorts).—Best of All, Green Curled, Latest of All, Norwegian, Ormskirk, and Perfection.—F. R. C.

CABBAGE TRIBE.—See *KINDS OF CROPS.*

CABBAGE WHITE BUTTERFLIES.—See *INSECT PESTS.*

CABBAGE WHITE FLY.—See *INSECT PESTS.*

CACALIA.—A synonym for ADENOSTYLES and EMILIA. See *ADENOSTYLES* and *TASSEL FLOWER.*

CACTI.

In every greenhouse from which frost can be excluded in winter a few at least of these fascinating subjects should be grown. They are unique amongst plants for the extended period over which they are capable of thriving without water—a fact which has earned for them the apt title of VEGETABLE CAMELS. They are extremely diverse in form, ranging from the miniature *Mamillarias* little larger than a thimble, covered with tiny symmetrically arranged spines and hairs, to towering *Cereus* and *Opuntias*, which may if wished be grown 7–8 ft. high. Cacti are as interesting in winter as in summer, affording a perennial attraction to the grower, and when they flower, although the period is as a rule brief in duration, this is compensated by the extreme brilliance of colouring and size of the blooms.

Soil.—A soil of which fibrous loam forms the greater portion, with a

sufficient addition of coarse sand and soft brick rubble pounded into small pieces to ensure extreme porosity, is suitable for the majority of genera, though *Epiphyllums* and *Rhipsalis* appreciate an addition of one-third of peat to this. To test the suitable condition of the soil pour water on to the surface. If suitable, the water immediately disappears.

Potting.—Always pot in the spring during March and April, so that the plants may become thoroughly established before the winter. Never interfere, however, with a plant that is doing well in sound, sweet soil, unless this is too fully occupied by healthy roots. When potting, make the soil moderately firm, so that the plants are firmly anchored and do not wobble about. For several weeks after potting give a minimum of water, or the plants will rot off wholesale. Small growers, such as many of the *Echinopsis* and *Mamillarias*, which make but little root, should have the pots three parts filled with crocking material, thus avoiding a large bulk of unnecessary soil, which is liable to become sour. Small pieces of charcoal added to the compost are beneficial in obviating sourness. Special care when crocking the pots should be given for all varieties. Place one large piece over the drainage hole, then smaller pieces over this until one-third of the depth is filled.

Watering.—This is *the* point which determines success or failure, and it is always better to err rather on the side of too little than on the slightest excess. From the end of April to the middle of August should be made the growing season, during which all plants should be kept moderately moist. The first watering after the winter should be done by immersing the pots to the rim in water and allowing them to remain for eight hours so as to soak the whole ball completely through, as this cannot be done by pouring it on the surface. No more will be needed for a week, after which with more sunlight, longer days, and an increasing temperature, fuller supplies should gradually be given. In the height of the growing season, when the house is closed for the night, a light syringing overhead is beneficial; but always bear in mind that these are desert plants and therefore moisture must not be overdone. After mid-August all syringing must cease, and root-watering must be considerably reduced, so that the growth made becomes well ripened, otherwise flowering will not be satisfactory. From early October until April the majority of Cacti require merely enough water at widely separated intervals to prevent shrivelling.

Epiphyllums, *Rhipsalis*, and *Phyllocactus* need slightly different management. *Epiphyllums* and *Rhipsalis* must never become dust dry at any time if their culture is to be successful, though very much less moisture must be given in winter than summer. *Phyllocactus* need a liberal supply throughout their growing season, with occasional applications of weak liquid manure. They should be syringed freely overhead each afternoon until growth is completed, and be kept always in a light, airy position. All through the winter give them only just sufficient water to prevent shrivelling.

Shading.—Very little in this way is requisite, the majority revelling in the hottest sunshine; but *Epiphyllums*, *Rhipsalis*, and *Phyllocactus* appreciate a slight screening, just sufficient to break the light during the hottest hours. A roller-blind is the best, as this can be run up immediately the sun declines. If a wash-on shade must be used, let this be as thin as possible.

Pests.—Cacti are singularly free from pests, the most troublesome being *Mealy Bug*, which, where it obtains a footing on specimens covered with hair or spines, is difficult to dislodge. A wineglassful of paraffin and two ounces of soft soap thoroughly mixed with a gallon of water, and kept continuously stirred, should be used for syringing affected plants. Lay these on their sides, and syringe vigorously, allowing them to remain wetted for several minutes. Then syringe again with clear water, repeating this treatment on several consecutive days.

Rotting of the Tissues.—This, a so-called disease, is almost always due to errors in watering. It quickly reduces a large and handsome specimen considerably in size, or results in its untimely death. Directly rotting is noticed, cut out every particle of decay with your sharpest knife, and lay the plant on a shelf in a dry air for three or four days until the wound has callused over. Then treat as a cutting, taking extreme care to avoid excess moisture.

Propagation.—This is effected by seed, cuttings, and offsets. Seed is sown in spring in a compost of equal parts finely sifted loam and sand, covering the pot with a sheet of glass, and standing in a temperature of 65° F. Plenty of moisture is needed until the little plants attain some size, since during their infancy they are little more than globules of water, and a few hours' sun when dry will burn them up.

Cuttings can be formed of any portion of a plant, large or small, in summer, and will soon form roots if placed in sandy soil and sparingly supplied with water. They are best removed from the parent plant with a sharp knife, so as not to bruise the tissue, and laid on a shelf in the sun for a few days before potting. When the top portion of a columnar or globular plant is used as a cutting, the base of the old plant should be retained in its pot, and kept slightly moist, when it usually puts out numerous offsets. These last, which are thrown off with great freedom by many varieties, simply need detaching and potting, after which they are treated as regards watering, etc., as cuttings until established.

Varieties.—The following is a selection of desirable easily grown sorts:—

Cereus caespitosus.—A compact dwarf species forming a cluster of stems. The flowers are bright rose in colour, and very freely produced in early summer. Height about 8 ins.

C. flagelliformis.—The WHIP or RAT'S TAIL CACTUS, with long trailing growths which attain a length of 3–4 ft. Its flowers are bright cerise red, and are freely produced in spring or early summer, according to the temperature in which it is grown.

C. grandiflorus.—This is a night blooming variety, opening its magnificent flowers about July. It is very fragrant. The colour is pure white inside, and reddish-brown on the outer petals. The flowers open very rapidly at sunset, closing at sunrise the next morning. Height, 2½–3 ft.

C. polycanthus.—This has intensely red flowers, which appear in spring, and the plant remains in blossom over an extremely long period, as the buds continue to open one after another. Height, 10 ins.

C. speciossimus.—This is a splendid variety for small houses, as it can be trained against a wall, where it bears its glorious crimson flowers, shaded to purple at the centre, with great freedom in April and May. Height, 6 ft.

C. triangularis.—This has stout triangular stems which grow very rapidly, and are well adapted for training over a conservatory roof.

Its flowers, which are white, appear in autumn, and are 12–14 ins. in diameter.

Echinocactus cornigerus.—This is a sort with unusually broad spines, producing blood-red flowers in summer. Height, 10 ins.

E. mamillarioides. — This has brilliant yellow flowers, with a red band down the centre of each petal. It blooms in summer. Height, 5 ins.

E. minuscula.—This is a small grower, freely producing orange-scarlet flowers in spring. Height, 3 ins.

E. rhodophthalmus. — A species bearing deep crimson flowers in autumn. Height, 4–12 ins.

E. Simpsonii.—This plant is so thickly spined that it is commonly known as the HEDGEHOG CACTUS. It bears red flowers, which appear in summer at the apex of the stems. Height, 4 ins.

E. uncinatus.—This bears deep purplish-red flowers in March or April. They are in clusters at the tops of the stems, and a striking contrast is afforded by the yellow stamens.

Echinocereus candicans (Syn. *Cereus rigidissimus*). — This is a splendid species, with flowers which are bright purple at the edges shaded to white at the centre, and are 4 ins. in diameter.

Echinopsis cristata purpurea.—This is a most brilliant variety, which bears deep rose-coloured flowers in July. The plant is globe-shaped. Height, 1 ft.

E. oxygona.—This species bears lovely rose-coloured flowers from the ridges near the centre of the stem. Height, 8 ins.

Mamillaria applanta.—This is a dwarf grower, the flowers, which are white tinged with red, springing from the outside of the stem at the top and appearing in summer. The plant is covered with red berries at the same time as the flowers.

M. elegans.—This is a very compact silvery-spined species, which very rarely flowers, the attraction being in the silvery spines. Height, 2 ins.

M. elephantidens.—This species has masses of closely curving spines set in tufts of white wood. It bears flowers of bright violet with a white margin in the autumn. The inner circle of the petals are rose-pink with purple base, and the flowers measure 3 ins. across. Height, 1 ft. or more.

M. pusilla.—This is a splendid species in shallow pans, bearing yellowish-white flowers in May. Its masses of small clustering silvery spines and ruby-red berries are most effective in winter. Height, 2 ins.

M. stella aurata.—This variety is covered with golden starlike rosettes of spines, and it bears yellow flowers in spring. Height, 3 ins.

M. viviparus.—The whole plant is covered with purple and white spines. It is splendidly free flowering, the blooms being purple in colour, and appearing in May and June.

Opuntia ficus indica (PRICKLY PEAR, or INDIAN FIG).—This is a tall grower, bearing yellowish flowers all through the summer, followed by mawkish-tasting fruits. Height, 8–12 ft.

O. leucotrichia.—This species has long white hairs, and bears yellow flowers in June.

O. mesacantha macrohiza. — A practically hardy sort, which may be grown out of doors beneath the wall of a greenhouse with south aspect. It has very few light greenish-brown spines, and flowers very freely, the blooms being yellow in colour, and followed by brownish-green fruits.

O. micro-dasys.—This is a sort specially liable to attack by mealy bug, but very pretty. It has battledore-like growths covered with delicate tufts of golden-brown spines.

O. missouriensis.—This species is

hardy, and bears attractive large yellow flowers 3 ins. in diameter from May onwards.

O. rafinesquii.—This is a prostrate species. The flowers are sulphur in colour, 3 ins. across, and appear very freely on the margins of the growths from July to September. Height, 9 ins.

Pereskia aculeata (BARBADOS GOOSEBERRY or BLOOD APPLE).—This species bears transparent-white flowers in panicles. The leaves resemble those of the orange tree, and the plant is useful for training on rafters or grafting other species in standard form. Height, 6 ft.

Phyllocactus. — All these have magnificent flowers of most intense colouring, and are very reliable annual bloomers in spring and early summer.

P. albus superbus.—This is the best creamy-white variety, and is very fragrant.

P. anguliger.—This bears small, very fragrant white flowers at the tips of the branches in December and January.

P. Edwardsii.—This is a garden hybrid, which bears red flowers of medium size.

P. Etoile de Poissy.—This is a garden variety, with orange flowers shaded violet.

P. Jules Schomberger.—This is an attractive deep blue garden variety.

P. phyllanthoides. — This is an especially free-flowering species, with rich rose flowers in early summer.

Pilocereus senilis (THE OLD MAN CACTUS).—This is densely covered at the top with long silky white hairs, which become grey with age, occasionally producing a few carmine-purple flowers.

Rhipsalis salinorcoides.—This is a sort which has thin angular stems and small tufts of hair when young. It bears small neutral-tinted flowers in spring, which are followed by long persisting pea-like berries, from which it derives its common name MISTLETOE CACTUS. Height, 1 ft.

H. W. C. W.

CACTUS DAHLIAS.—See DAHLIA SECTIONS AND VARIETIES in *DAHLIA: CULTURE OF.*

CÆNOPTERIS.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

CAESALPINIA.—For the best species see *SHRUBS.*

CAFFRE LILY.—See *KAFFIR LILY.*

CAKILE.—See *SEA ROCKET.*

CALABRIAN PINE (*Pinus pyrenaica*). See *TREES.*

CALAMAGROSTIS (Nat. Ord. Gramineæ).—This is a genus of weedy plants of no garden value whatever. The best known species is *C. epigeios*, the COMMON WOOD REED.

CALAMINT (*Calamintha.* Nat. Ord. Labiatæ). — This is not much grown, but it is somewhat ornamental and may well be included in big gardens. All the species are hardy and of very easy culture, thus they are good plants for beginners. See also article on *POTHERBS.*

Annual Species.—These are sown out of doors in a sunny site in late March or April. Only one species need be described here :—

Calamintha Acinos.[1]—A species with purplish-blue flowers which open in July. Its height averages about 6 ins.

Perennial Border Species. — We describe a few good sorts below :—

Calamintha caroliniana.—A bright red, scarlet, or crimson sort, vivid and attractive, blooming from June onwards. Height about 12 ins.

C. coccinea.—An attractive bright scarlet sort, blooming all the summer. Height, 12–24 ins.

C. grandiflora.—This is the species usually grown. There appear to

[1] This is known as BASIL THYME.—EDITOR.

be several forms of it. Authorities describe it variously as a red and a purple. The form we are familiar with is, however, a bright rose one. It blooms from July onwards, and averages about 1 ft. high.

C. mimuloides.—An attractive sort, with flowers which are almost orange coloured. It blooms in June and July, and averages 18 ins. high.

Rock Garden Species.—Only one species is suitable for the rock garden. This thrives in sunny situations if set in gritty soil, and is propagated by seeds sown in the spring. It seeds itself readily if left alone.

Calamintha alpina.—A plant of neat habit producing purple flowers in June and July. Its height averages about 4 ins.

See also *POTHERBS.*

CALAMINTHA.—See *CALAMINT.*

CALAMPELIS.—Now included in the genus ECCREMOCARPUS.

CALANDRINIA (ROCK PURSLANE. Nat. Ord. Portulaceæ).—There are a number of hardy annual species of Calandrinia, but few are garden favourites. They are of lowly growth, and best suited to sunny positions in the rock garden, as the flowers open only under the influence of sunshine. *Calandrinia grandiflora,* the COMMON ROCK PURSLANE, bears rose-purple flowers in July, on plants 12 ins. high, and is doubtfully annual, but succeeds as such in light warm soils if sown in autumn or spring, as well as being a useful plant for dry walls. *C. Menziesii* (Syn. *C. speciosa*) bears rose-purple or crimson-purple flowers throughout the summer, and grows 9 ins. high. *C. umbellata* is probably a biennial, but nevertheless a charming little plant when treated as a hardy annual; it bears vivid rosy-crimson flowers about half an inch across, from July onwards, and averages about 6 ins. high. It must be remembered that Calandrinias thrive only in light, well-drained soil and sunny positions.—C. H. C.

[A number of stove species as well as greenhouse species have been described and are often listed in gardening dictionaries. We do not, however, consider them of sufficient importance to include them here.—EDITOR.]

CALANTHE.—See *ORCHIDS.*

CALATHIAN VIOLET (*Gentiana Pneumonanthe*).—See *GENTIANA.*

CALCEOLARIA (SLIPPER-WORT. Nat. Ord. Scrophulariaceæ).—Herbaceous perennials, for greenhouse and half-hardy treatment. Height, 9–24 ins. The best soil is fibrous loam two parts, old manure and leaf-soil one part each, and a little silver sand. Propagation is by seed or by cuttings.

Culture.—Calceolaria seed is very minute and should be sown thinly and only just covered with fine soil. The seed-pans must be heavily shaded till germination takes place, and the soil kept evenly moist. Towards the end of July is a good time for sowing, and the seedlings should be pricked out early and kept growing on without check. After potting off singly, the young plants must be given a further shift as soon as the roots reach the edges, and so on till the final potting into 7- or 8-inch pots. Thorough ventilation, a cool moist temperature, and cleanliness are essential to success. If aphis is troublesome, mild fumigation should be resorted to.

The true florists' calceolarias are the herbaceous species, and these are usually raised from seed and grown in a cool greenhouse. The shrubby species, on the other hand, are easily propagated from cuttings taken in autumn and wintered in a frost-proof frame, or glasshouse. These are widely used as bedding

plants, and will bloom practically all summer.

Varieties.—Calceolarias are not usually sold as named sorts, but many brilliant colours are procured from a choice strain of seed, of which many seedsmen have their own.

J. L. G.

CALCEOLARIA: Rock Garden Species.—These are well worth growing, and are of tufted habit, deciduous, and will thrive in half-shady positions. They are propagated by division of the roots in the autumn and spring.

Calceolaria plantaginea.—Leaves large green, in rosettes close to the ground. Flowers yellow. Site half-shady. Soil well-drained gritty loam. Flowering Period, June to August. Height, 1 ft.

C. polyrrhiza.—Smaller than above, spreading by undergrowths. Flowers yellow, with brown spots. Flowering Period, June to August. Height, 9 ins.

CALCIUM.—This element is frequently referred to in this work. See *CHEMISTRY FOR GARDENERS, LIME, LIME COMPOUNDS*, etc.

CALCIUM CARBIDE REFUSE.—See CALCIUM CARBIDE IN *LIME COMPOUNDS*.

CALCIUM COMPOUNDS.—The chief are described in *LIME COMPOUNDS*.

CALENDAR.

A Calendar covering Greenhouse Work, Hardy Fruit Work, Indoor Fruit and Vegetable Work, and Outdoor Flower Gardening will be found as a supplement at the end of the volume.

CALENDULA.—See *MARIGOLD*, and under MARIGOLD in *MEDICINAL HERBS*.

CALICHE.—See under FORMS OF SODA in *SODA AND SODIUM COMPOUNDS*.

CALICO AS GLASS.—See *GLASS SUBSTITUTES*.

CALICO BUSH (*Kalmia latifolia*).—See *SHRUBS*.

CALIFORNIA LILAC (*Ceanothus thyrsiflorus*).—See *SHRUBS*.

CALIFORNIA NUTMEG (*Torreya californica*).—See *TREES*.

CALIFORNIAN ALLSPICE (*Calycanthus occidentalis*).—See *SHRUBS*.

CALIFORNIAN BLUEBELL.—See *NEMOPHILA*.

CALIFORNIAN CARPENTARIA (*Carpentaria californica*).—See *CLIMBING AND TRAILING PLANTS*.

CALIFORNIAN FUCHSIA.—See *ZAUSCHNERIA*.

CALIFORNIAN FUCHSIA CURRANT (*Ribes speciosum*).—See *CLIMBING AND TRAILING PLANTS*.

CALIFORNIAN POPPY (*Platystemon*. Nat. Ord. Papaveraceæ).—In warm and sunny gardens this hardy annual, botanically known as *Platystemon californicus* (Syn. *P. leiocarpus*), is a very cheerful plant, about 9 ins. high, with pale yellow flowers carried on slender stems. The best results are obtained by sowing in the open ground in spring or autumn, and thinning the seedlings so that they stand 4–6 ins. apart. It is most effective when grown in groups, and sows itself freely.

C. H. C.

[This must be carefully distinguished from Eschscholzia, which is sometimes known as the Californian Poppy.—EDITOR.]

CALIFORNIAN REDWOOD (*Sequoia Sp.*).—See *TREES*.

CALIFORNIAN TREE POPPY (*Romneya trichocalyx*).—See *SHRUBS*.

CALIFORNIAN or WESTERN ALLSPICE (*Calycanthus occidentalis*).—See *SHRUBS*.

CALIFORNIAN YEW (*Taxus brevifolia*).—See *TREES*.

CALIMERIS.—Now included in the genus *ASTER*.

CALLIANTHEMUM (Nat. Ord. Ranunculaceæ).—Closely related to Ranunculus. Only one species is usually grown. This requires a well-drained gravelly loam, and is propagated by division of the roots

in the autumn. It may be also raised by means of seed sown as soon as ripe.

C. rutaefolium (Syn. *C. anemonoides*).—A dwarf, hardy perennial rock plant, with Rue-like leaves in rosettes. Flowers white, tinged with purple when old. Site half-shady. Flowering Period, May to June. Height, 4 ins.

CALLICHROA.—Now included in the genus LAYIA.

CALLIOPSIS.—See *COREOPSIS.*

CALLIPRORA.—Now included in the genus *BRODIAEA.*

CALLIPTERIS.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

CALLIRHOË.—See *POPPY MALLOW.*

CALLUNA.—See *HEATHS* and *SHRUBS.*

CALLUS. — See *PROPAGATION OF PLANTS* for explanation of this term.

CALOCHORTUS. — See *MARIPOSA LILIES, or STAR TULIPS.*

CALOPHANES (Nat. Ord. Acanthaceæ).—This is not widely known or widely grown, but comes in as a hardy perennial for the herbaceous border.

Culture.—This requires the usual treatment given to other hardy perennials. It may be successfully grown out of doors in a sandy soil to which some peat has been added. It may be planted in the autumn or spring, and is increased by division of the roots in February.

What to Grow.—Only one sort has come to my notice as being worthy of cultivation. Future research may show the presence of others. The species in question (*Calophanes oblongifolia*) bears a blue flower dotted with violet or purple. It blooms from August onwards, and averages about 12 ins. in height.

CALOSCILLA.—Now included in the genus *SCILLA.*

CALTHA (MARSH MARIGOLD. Nat. Ord. Ranunculaceæ).—This is a genus of hardy herbaceous perennials more suitable for the water garden than the borders, though they will succeed in the latter site if kept very moist. The best known species is *C. palustris.* See MARSH MARIGOLD in article on *WATER GARDEN: PLANTS FOR THE. C. polypetala* is a new species well worthy of culture. It bears large yellow flowers in May, and grows 1–2 ft. in height. This plant must be carefully distinguished from a plant of similar name, MARSH MALLOW (*Malva sylvestris*), an important medicinal plant described under MALLOW in our article on *MEDICINAL HERBS.*

CALVARY CLOVER (*Medicago Echinus*).—See *MEDICAGO.*

CALYCANTHUS.—For the best species see *SHRUBS.*

CALYSTEGIA (BEAR-BIND. Nat. Ord. Convolvulaceæ).—This is a rather large genus of hardy and half-hardy perennial or evergreen twiners and trailers of little garden value. Probably the most suitable as well as the most attractive is *C. Soldanella,* a flame-coloured June and July blooming plant about 12 ins. high, though *C hederacea plena* (Syn. *C. pubescens*) is a good dwarf rose-coloured twiner. *C. sepium* is the well-known weed the GREATER BINDWEED or COMMON BEAR-BIND, a most troublesome plant the best means of dealing with which will be found described in our article on *WEEDS* under the former name.

See also *CLIMBING AND TRAILING PLANTS.*

CAMASSIA (QUAMASH. Nat. Ord. Liliaceæ).—This is a hardy bulbous plant from North-West America, which flowers in late spring or in summer. The blooms are borne on erect, somewhat slender stems, which vary in height from 1–3 ft., and as they are invariably of some shade of blue, mauve, or white, they make pleasing and somewhat

unusual variations in a mixed border. As the different varieties seed freely in a warm summer, and as the young seedlings vary considerably in their colour and habit, it is worth while trying to raise one's own seedlings.

Culture.—Camassias are naturally at home in rich meadows, which are moist during winter and spring, but rather dry in summer. Under cultivation they like a good loam inclining to the stiff side and enriched with leaf-mould and old manure, but they will thrive in any good border soil. The bulbs should be planted in September or October at a depth of about 4–6 ins., and they may be left undisturbed for several years.

Seed should be sown thinly in drills in a bed where the seedlings may remain for two years, when they may be transferred before new growtn commences to another seed bed. Here they may remain until they flower, which will probably be in their third or fourth year from seed, and the best varieties picked out for border decoration. Seed should be sown soon after it is ripe.

Varieties :—*Camassia Cusickii.*—The large bulb is very characteristic. The flowers, which are of a delicate pale blue or mauve, open in June or early July, and are borne on stems often 3 ft. high.

C. esculenta.—This is the typical Quamash of the Indians, who eat the bulbs when baked. The flowers vary in colour from almost white to a deep blue, and twenty to forty are usually borne (in June) on one stem. The height is 1½–2½ ft. Fancy names have been given to some of the best of the seedlings.

C. Fraseri (Wild Hyacinth).—This bears lovely sky-blue flowers in May or June, on plants 1½ ft. high.

C. Leichtlinii.—This bears creamy-white flowers in May, and averages 3–6 ft. in height.—J. J. & E.

CAMBIUM.—For explanation of this term see under Growth in *Plant Physiology.*

CAMBRIDGE BLUE GRAPE HYACINTH (*Hyacinthus azureus*).—See *Grape Hyacinth.*

CAMELLIA (Nat. Ord. Ternstroemiaceæ).—This is an evergreen flowering shrub, hardy in the milder parts of Britain, averaging 3–20 ft. or more in height. For growing in pots or tubs, a good compost is medium turfy loam and peat in equal proportions, kept porous with plenty of sharp silver sand. A peaty loam is most suitable for outdoor culture. Propagation may be effected by seed, grafting, or layering, the two latter methods being most suitable for amateurs.

Culture.—Grafting is best done in the early spring, the stock usually employed being *C. japonica,* this being the hardiest species. Maiden plants of this stock should be cut down to within 2 or 3 ins. of the base, and the selected variety grafted thereon.

Uses.—As the Camellia blooms early (February to May), the flowers are frequently ruined by frost in the open. The plants are, therefore, more suited for conservatory decoration, either set out in beds or placed in large pots and tubs.

Varieties.—The best of the species are probably *C. japonica magnoliaeflora* and *C. reticulata.* Of garden hybrids the following are excellent, prominence being given to the now fashionable single-flowered sorts: Alba plena, Alba simplex, Apollo, Donckelaarii, Jupiter, Snowflake, and Waltham Glory.—J. L. G.

See also *Climbing and Trailing Plants* and *Shrubs.*

CAMPANULA (Bellflower or Bellwort. Nat. Ord. Campanulaceæ).—This genus contains

something like two hundred and thirty species of annual, biennial, or perennial flowers, mostly the latter. In the present work it will be impossible to describe more than a very small proportion of those specially worth commendation.

Annual Species.—Only a few of the hardy annuals need be troubled about by the everyday gardener. The following, however, are exceedingly beautiful :—

Campanula drabaefolia.—This is a Grecian plant of lowly growth, and its variety *attica*, often listed as a separate species, is the best to grow. It produces a dense mass of purple-blue flowers all the summer, and grows about 4 ins. high. Seed may be sown in the spring or autumn, in the flowering positions. There is a white variety called *alba*.

C. Erinus.—This is a suitable annual for the rock garden. It produces rosy-blue flowers throughout the early and late summer on stems which branch very freely, and its height is about 6 ins.

C. macrostyla.—This is a most distinct species having stiffly-branched stems and producing glorious purple flowers veined with violet, from July onwards. Its hardiness is doubtful, and thus it should be given a warm position. Its height is 18 ins.

C. ramosissima.—This is a useful annual for the border, producing blue flowers with a white base freely during the summer. It grows about 9–12 ins. in height.—C. H. C.

Biennial Species.—These require the usual treatment for biennials and are useful for the border or rockery.

Campanula sibirica.—This produces bluish-violet flowers from July onwards, and grows 12–18 ins. in height. The variety *divergens* is preferable to the type.

C. thyrsoides.—This bears attractive sulphur or pale yellow flowers from July onwards, and grows about 12–18 ins. in height.

Perennial Border Species.—These and the rock garden species to follow are the most important, thriving as they do in a great variety of soils. A large number of them, such as *Campanula glomerata, C. lactiflora, C. latifolia,* and *C. persicifolia,* are equally as happy under deciduous trees in woodlands as they are in the perennial border. Where the soil is heavy all Campanulas should, however, be planted in as open sunny spots as possible. Propagation is easily effected by seeds, cuttings, offsets, and division of the roots, and the seed, which is very small, is best sown in pots, pans, or boxes of finely sifted sandy soil during May or June, the resulting plants being pricked off in frames of light soil and protected from slugs. Spring planting is the best, and small plants should not be put out of doors too soon. Division of the roots, however, is by far the most satisfactory and speedy method of increasing one's stock. The following is a selection of the best species :—

Campanula alliariaefolia. — This pretty species has heart-shaped leaves, and produces long creamy-white, bell-shaped drooping flowers from June to July. Height, 2–3 ft.

C. americana.—This erect species, with egg-shaped leaves, bears blue flowers in July, and grows 3–6 ft. high.

C. betonicaefolia. — This very branching species has long, oblong, egg-shaped leaves, and produces attractive blue-purple flowers in May. Height, 1½ ft.

C. bononiensis.—The lower leaves of this attractive species are heart-shaped, and its violet-blue flowers are produced in July. *C. b. alba* is white, and both grow 2–3 ft. high.

C. celtidifolia.—A synonym of *C. lactiflora*, which see.

C. collina.—The dark blue funnel-shaped flowers of this are produced in July, and the plant grows about 1 ft. high.

C. glomerata.—This useful sort, the lower leaves of which are egg-shaped, produces attractive blue-purple flowers of medium size from May to September. The following are good varieties of it:—*alba* (white); *dahurica* (violet-purple); and *pusilla* or *acaulis* (blue); and all grow 1–2 ft. in height, except the last-named, which grows only 1–2 ins.

C. grandis.—A synonym of *C. latiloba*, which see.

C. lactiflora (Syn. *C. celtidifolia*).—This attractive sort bears milky-white flowers shaded with light blue, though pure white and sky-blue varieties have also been raised. The bloom is produced from July to September, and the height varies from 2 ft. to 6 ft.

C. latifolia. — The purple-blue flowers of this sort are narrowly bell-shaped and are freely produced from June to August. The following are useful varieties:—*alba* (white); *Burghalti* (lavender-blue); *macrantha* (royal purple); *Van-Houttei* (dark blue); and *versicolor* (light and dark purple). All grow from 2 ft. to 4 ft. in height.

C. latiloba (Syn. *C. grandis*).—This attractive sort produces light blue flowers in dense clusters during June or July, and its variety *alba* is pure white. Both grow 1–3 ft. high.

C. longistyla. — This useful sort bears blue-purple bell-shaped flowers from June to September, and grows 2–2½ ft. high.

C. lyrata.—The numerous attractive blue flowers of this sort are produced in June, on plants growing 1–2 ft. high.

C. Medium. See article on *Canterbury Bells.*

C. nobilis.—A synonym of *C. punctata*, which see.

C. peregrina.—The flowers of this are similar to those of *C. latiloba* in some respects. They are light blue, with a dark centre, and are produced in July, on plants 2½ ft. high.

C. persicifolia. — The nodding flowers of this sort are blue and widely bell-shaped. They are produced from July to September, on plants 1–3 ft. high. Garden varieties, both single and double, are very numerous.

C. phyctidocalyx.—This produces rich dark blue-purple widely bell-shaped flowers from May to July. Its height is 2–3 ft.

C. primulaefolia.—The flowers of this sort are densely arranged after the style of *C. latiloba.* They are blue or purple and are produced in July, on plants 1–3 ft. high.

C. punctata (Syn. *C. nobilis*).—This bears reddish-purple, cream, or white spotted flowers in July, on plants 1½–2 ft. high.

C. pyramidalis. See article on *Chimney Bellflower.*

C. rapunculoides. — This plant must be kept away from other choice subjects as it spreads rapidly. Its blue-purple flowers are freely produced from June to August, on plants 2–3 ft. high.

C. Rapunculus. See article on *Rampion.*

C. sarmatica.—This useful sort bears pale blue or purple bell-shaped flowers in July, on plants 1–2 ft. high.

C. speciosa.—This most useful sort bears purple and white flowers of medium size in a pyramid on the upper part of the unbranched stem. Its flowering period is June and July, and its height 1–2 ft.

C. Trachelium (Nettle Leaf Bellflower).—This attractive sort bears blue-purple bell-shaped nodding flowers in small clusters at the top of its stem from June to Sep-

tember. The best double varieties are:—*alba plena* (white); and *caerulea plena* (blue); both of which grow 1–3 ft. high.

C. versicolor.—The flowers of this are pale violet at the tops, purplish in the middle, and dark violet at the base. They are produced from July to September, and are widely bell-shaped and very attractive. The height of the plant varies from 3 to 4 ft.—J. F.

Rock Garden Species.—Most of these thrive in half-shady situations if planted in well-drained, sandy loam, and as a rule they are easily propagated by division of the roots in the spring, or by seed sown in gentle heat in March. The following is a selection of the most useful sorts, those difficult to grow being purposely omitted:—

Campanula abietina.—This has tufted leaves forming a mat. Flowers light blue on branching stems. Site, half-shade. Soil rich, gritty loam. Flowering Period, May to July. Height, 9 ins.

C. acutangula.—Syn. *C. arvatica*, which see.

C. Allionii. — This spreads by underground runners, bearing leaves in tufts, and large solitary bluebell-like flowers. Site sunny. Soil very gritty or morainic. Flowering Period, June to July. Height, 3 ins.

C. alpina.—This bears leaves in rosettes. Flowers light blue on branching stems. Site sunny. Soil morainic. Flowering Period, July to August. Height, 4 ins.

C. arvatica (Syn. *C. acutangula*). —This spreads by underground runners and has small ivy-like leaves close to the ground. Flowers lilac or purple, wide open. Site, half-shade. Soil very gritty or morainic. Flowering Period, May to July. Height, 2 ins.

C. carpatica.—This has leaves in large tufts and is a free grower. Flowers blue to white. Site, sun or half-shade. Soil rich, gravelly loam. Flowering Period, May to September. Height, 1 ft.

C. excisa.—This spreads by underground runners. Leaves narrow on wiry stems. Flowers blue, drooping, perforated. Site sunny. Soil very gritty or morainic. Flowering Period, June to August. Height, 3 ins.

C. garganica.—This is a free-growing dwarf plant with small ivy-like leaves. Flowers blue, with white centre, starlike and freely produced. Site, half-shade. Soil rich gritty loam or crevice. Flowering Period, May to August. Height, 3 ins. The variety *alba* has white flowers, and the variety *hirsuta* has hoary leaves.

C. muralis.—Syn. *C. Portenschlagiana*, which see.

C. planiflora.—This is a small counterpart of *C. persicifolia.* Flowers large blue. Site sunny. Soil rich gritty loam. Flowering Period, July to August. Height, 8 ins.

C. Portenschlagiana (Syn. *C. muralis*).—This is one of the best dwarf species, and is of tufted habit. Flowers blue-purple in long racemes. Site, half-shade in rock crevices. Soil gritty. Flowering Period, June to August. Height, 4 ins. The variety *bavarica* has larger flowers.

C. pulla.—This is one of the choicest kinds. Flowers deep rich violet almost hiding the foliage. Site, half-shade. Soil rich and well drained, gritty. Flowering Period, June to September. Height, 3 ins.

C. pusilla (Syn. *C. pumila*).—This is a free-growing species, spreading by underground runners and coming up freely from self-sown seeds. Flowers blue to white. Site, half-shade. Soil gritty or

rock crevice. Flowering Period, June to September. Height, 3 ins.

C. Raineri.—This is a rare plant. Flowers saucer shape, deep blue and borne on short leafy stems. Site, half-shade. Soil morainic. Flowering Period, June to July. Height, 3 ins.

C. rhomboidalis.—This is a bushy plant with leafy stems. Flowers blue. Site, half-shade. Soil moist. Flowering Period, June to July Height, 1 ft.

C. rotundifolia (HARE-BELL).—This has wiry branching stems, and is very useful for the rock garden. Flowers deep blue to white. Site, half-shade. Soil gritty loam. Flowering Period, June to September. Height, 1 ft.

C. Stansfieldi.—This is very free flowering. Flowers violet-blue on branching stems. Site, half-shade. Soil gritty. Flowering Period, June to July. Height, 4 ins.

C. Tommasiniana.—This has a mass of wiry stems clothed with narrow leaves. Flowers pale blue, pendent in long racemes. Site sunny. Soil gritty or rocky crevice. Flowering Period, July to August. Height, 6 ins.

C. Waldsteiniana.—This grows into neat little bushes of wiry stems. Flowers pale blue. Site, half-shade. Soil gritty loam or rock crevice. Flowering Period, June to July. Height, 3 ins.

C. Zoysii.—This is a choice little gem making a compact bush-like plant. Flowers curious shape, azure blue. Soil morainic or very gritty and well drained. Flowering Period, June. Height, 3 ins.—W. I.

NEW VARIETIES.

Campanula Abundance. — This bears light blue flowers, several on a stem, and grows 6–8 ins. high. It is suitable for pot or rock garden culture.

C. cenisia alba.—This is a pretty white subject for the rock garden, growing 1 in. high.

C. Chastity.—This bears white bell-shaped flowers, and is of erect habit, growing 6 ins. high. It is best grown in pots.

C. Enchantress.—This is a pale mauve sort growing 6 ins. high, and most suitable for the rock garden.

C. garganica W. H. Paine.—This bears blue flowers with a white eye. It is a trailer suitable for the rock garden.

C. Meteor.—This bears white flowers with a violet eye, on plants 4 ins. high. It is best grown in pots.

C. Norman Grove.—This bears light blue bell-shaped flowers, and grows 3 ins. high. It is suitable for pot and rock garden culture.

C. persicifolia Telham Beauty.—This bears deep lavender flowers, on plants 3½ ft. high.

C. Phyllis Elliott.—This bears erect, bell-shaped violet-blue flowers about an inch across, and grows about 3 ins. high. It is best grown in the rock garden.

C. pusilla Miss Willmott.—This bears pale violet-blue flowers twice the size of the type. It grows 3–4 ins. high, and is suitable for rock garden culture.

C. tomentosa Maud Landale.—This bears rosy-purple funnel-shaped flowers and felted leaves. It grows 6–12 ins. high, and is suitable for rock garden culture.—W. J. C.

CAMPERNEL (*Narcissus odorus*).—See *NARCISSUS SPECIES.*

CAMPION.—A name applied to *SILENE*, which see; also *LYCHNIS.*

CAMPTERIA.—Now included in the genus PTERIS. See *FERNS AND FERN GARDENING.*

CAMPTOSORUS.—See *Scolopendrium rhizophyllum* in *FERNS AND FERN GARDENING.*

CAMPYLONEURON.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

CANADA MOONSEED (*Menispermum canadense*).—See *CLIMBING AND TRAILING PLANTS.*

CANADA PLUM (*Prunus nigra*).—See *TREES.*

CANADIAN ELDER (*Sambucus canadensis*).—See *TREES.*

CANADIAN FLEABANE.—See under ERIGERON in *MEDICINAL HERBS.*

CANADIAN LILY (*Lilium canadense*). See *LILIES.*

CANADIAN RED PINE (*Pinus resinosa*). See *TREES.*

CANADIAN WHORTLEBERRY (*Vaccinium canadense*).—See *SHRUBS.*

CANADIAN YEW (*Taxus canadensis*). See *TREES.*

CANARY CREEPER (*Tropaeolum aduncum*, or *T. peregrinum*).—See *NASTURTIUM* and *CLIMBING AND TRAILING PLANTS.*

CANARY GRASS (*Phalaris canariensis*).—See *PHALARIS.*

CANARY REED.—See *PHALARIS.*

CANDLE RUSH (*Juncus effusus*).—See *JUNCUS.*

CANDYTUFT (*Iberis.* Nat. Ord. Cruciferæ).—The immensely popular annual Candytufts are easily grown from seeds sown in the open ground in March; and their cultivation presents few difficulties. Lime in the soil and a sunny position are two essentials. As the seedlings make tap roots they resent being transplanted, and should therefore be raised where they are to flower, and thinned out in due course. Florists have raised several distinct types known as Hyacinth-flowered, Rocket, and Spiral, and have produced a modest range of colouring. The two best annual species are described below :—

Iberis amara (Syns. *I. arvatica, decipiens, Forestierii,* and *ruficaulis*).—The native BITTER CANDYTUFT white, and summer-flowering. The progenitor of the handsome large-flowered Spiral and Hyacinth-flowered strains. Height, about 10 ins.

I. umbellata (Syns. *I. coronaria, corymbosa, hortensis, pulchra,* and *Raynevalii*).—A purple, summer-flowering sort, native of Southern Europe. From this species and its forms the pink, rose, carmine, blush, crimson, and rich purple garden varieties have been produced, as well as the fine Rocket Candytufts. Height, 1 ft.

Rock Garden Species.—These are free-flowering, mostly perennial, plants with evergreen foliage, thriving in any open sunny place in the rock garden. They are propagated by division of the roots in the autumn or spring. The five best are briefly described :—

Iberis correaefolia.—A plant of shrubby habit, with evergreen foliage. Flowers white. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 1 ft.

I. gibraltarica.—This also is shrubby. Flowers rosy-lilac. Site sheltered, sunny. Soil sandy loam. Flowering Period, December to January. Height, 1 ft.

I. saxatilis.—A very dwarf bushy plant. Flowers white. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 3 ins.

I. sempervirens (EVERGREEN CANDYTUFT).—A sort forming dwarf bushes or pendent curtains covered with snow-white flowers. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 1–3 ft. There are many varieties of this, including *garrexiana.*

I. Tenoreana.—A free-flowering annual species. Flowers pale rosy-lilac. Site sunny. Soil sandy loam. Flowering Period, spring and autumn. Height, 6 ins.

CANKER.—See APPLE CANKER in *APPLE DISEASES.*

CANKER DISEASES.—See *DISEASES OF PLANTS.*

CANKER IN TOMATOES.—See TOMATO CANKER in *TOMATO DISEASES.*

CANKER LETTUCE (*Pyrola rotundifolia*).—See *PYROLA*.

CANKER WORMS.—See under WINTER MOTHS in *INSECT PESTS*.

CANNA (Nat. Ord. Scitaminaceæ). These were formerly treated as stove plants, but are really half-hardy perennials. Height, 2–5 ft. A rich, loose, loamy soil with plenty of humus suits them, and they are propagated by seed, and division of the rootstocks. (The latter is the usual method of increase and the only way to perpetuate the named varieties.)

Culture.—Seed, which should be soaked in warm water for some hours before sowing, requires a fairly high temperature for germination. Sow in February or March in pots, burying the seeds about ½ inch deep in light, well-drained soil. A brisk hotbed giving a bottom temperature of 75° F. will hasten the seedlings into growth. Pot off singly as soon as the young plants can be handled. Root divisions are potted up in 5-inch pots in spring, where, in a warm house, they will soon start into vigorous growth. If for growing in beds in the open, they are planted out in June in heavily manured sites where frequent watering can be given during dry weather. For pot culture shift the plants into 10- or 12-inch pots, using very rich soil. When well established, and the roots are beginning to fill the pots, weekly applications of dilute liquid manure will be appreciated.

Winter treatment is similar to that required by the *DAHLIA* (which see). The time of flowering is late summer and throughout autumn.

Varieties.—Alphonse Bouvier, Baron de Richter, Black Prince, Duc Ernst, Elizabeth Hoss, Evolution, Gaekwar of Baroda, J. B. Van der Schoot, Jupiter, King Humbert, Meteor, Niagara.—J. L. G.

CANNERIES, REFUSE FROM. — See REFUSE FROM CANNERIES in *FISH AS MANURE*.

CANNING FRUIT.

Is home canning of fruit and vegetables a very difficult matter? This question so often asked may be answered in the negative, as long as attention is strictly paid to the important detail of expelling the air from the cans and complete sterilisation. We propose to give a few hints on how this important operation of home canning may be carried out.

Apparatus Needed. — Simple apparatus as in the list below is required :—One thermometer; one canner or boiler, or a very large pan; a supply of suitable cans and lids; a pair of tongs for removing hot cans; one camel-hair brush; two soldering-irons, and a supply of flux and sticks of solder; a large bucket; a level table; a good file; and an abundant supply of both hot, cold, and boiling water will also be needed.

How to Can.—The operation of canning may be divided into six different heads.

First.—Sorting and cleaning of the fruit and vegetables.

Second.—Packing the cans.

Third.—Filling up the cans with water or syrup.

Fourth.—Sealing the cans, and exhausting the air inside.

Fifth.—Sterilising or processing; and

Sixth.—Cooling the cans and testing for leakages.

Before starting to can any fruit or vegetables thoroughly scald all the cans in boiling water. Next get the water in the canner or boiler up to 212° F., and see that the soldering-irons are quite clean and free from rust. It is necessary to heat the soldering-irons till they are nearly red-hot, and the copper

tip of each must be plainly visible. The irons are then dipped into the flux, touched with a stick of solder, and again dipped quickly into the flux, after which the solder will run evenly on the surface.

As regards the fruit or vegetables, those which are perfectly fresh, and not overripe, but in the best possible condition, should be chosen. Pack into clean cans to within about a quarter of an inch of the top, and fill up the cans with boiling water or syrup so as just to cover the fruit. Then immediately put on each lid and solder down, afterwards sealing up the tiny vent-hole in the centre of the lid.

The cans are now ready to go into the canner to be sterilised. The lengths of time necessary for processing are given in a table farther on. The time necessary for complete sterilising must be calculated from when the thermometer again reaches 212° F., as, of course, the temperature falls at once when cold cans are put into the canner.

When the prescribed time is up, each can should be carefully removed and put into a bucket of cold water, which prevents the fruit from becoming "mushy."

Both fruit and vegetables are usually prepared for canning in exactly the same way as for bottling (see article on *FRUIT BOTTLING AND PRESERVING*), but the borax mixture for keeping peas a good colour is usually omitted from the canned produce. It should be noted that Rhubarb and Beetroot are not satisfactory for canning.

All cans should be labelled immediately to avoid confusion, and stored in a cool dry place after being examined in the usual way for leakages.

Time Required.—The following are suitable times for sterilising when canning:—

Apples	10–20 minutes.
Apricots	15–20 minutes.
Asparagus	Intermittent.[1]
Beans	Intermittent.
Blackberries	12–20 minutes.
Carrots	120 minutes.
Cherries	20 minutes.
Cooking Pears	30 minutes.
Currants	12–20 minutes.
Damsons	12–20 minutes.
Gooseberries	12–20 minutes.
Mixed Vegetables	2 hours or Intermittent.
Peaches	15–20 minutes.
Pears	10–20 minutes.
Peas	Intermittent.
Plums	12–20 minutes.
Raspberries	12–20 minutes.
Strawberries	12–20 minutes.
Tomatoes	20–30 minutes.

Thorough sterilising, we may again insist, is essential to success.

E. C.

CANOE BIRCH (*Betula papyrifera*).—See *TREES*.

CANOE CEDAR (*Thuya plicata*).—See *TREES*.

CANTERBURY BELLS (*Campanula Medium*. Nat. Ord. Campanulaceæ).—This is one of the most popular races of biennial Campanula, and has given rise to a great number of varieties, bearing numerous large and handsome flowers, ranging in colour from white, blush, and pink, to rose, mauve, blue, purple, and striped. Besides the ordinary single forms there are double, or hose-in-hose varieties, and the cup-and-saucer strain (*C. Medium calycanthema*), in which the calyx has become expanded like a large saucer under each flower, and is coloured like the corolla.

Culture.—Seeds of any of these may be sown in a bed of finely raked soil in the open garden during May or June; but better results are ensured by sowing thinly in boxes in May, June, or July, and rearing the seedlings in a cold frame, where

[1] Intermittent sterilising is the equivalent of sterilising on three successive days for 45 minutes to 212° F.

they will be safer from the slug pest and other enemies. When a few rough leaves have been made, transplant the seedlings into a nursery bed of good soil, 12 by 4 ins. apart. Plant them where they are to bloom, in autumn, the earlier the better. They bloom in June and July, and vary from 1–4 ft. high, according to the size of the plants and the fertility of the soil, making pyramids of bloom on branching stems. If the soil is very heavy or wet, it should be lightened with old mortar broken finely, or road sweepings.

What to Grow.—The three kinds are briefly described below :—

Single.—All the colours as above, separate or in mixture. They bloom in June and July, and vary from 1–4 ft. in height.

Double.—Blue, pink, white, etc. They bloom in June and July. Height, 1–4 ft.

Cup and Saucer.—Blue, pink, mauve, white, etc. They bloom in June and July, and average 1–4 ft. high.—J. F.

CAP PLANT (*Silphium perfoliatum*).—See *SILPHIUM.*

CAPACITY OF BARRELS, CYLINDERS, TANKS OR BOXES.—See under VOLUMES in *ARITHMETIC AND GARDENING.*

CAPE ASTER (*Charieis.* Nat. Ord. Compositæ).—The genus Charieis has apparently only one species. It is decidedly interesting, however, and suggests possibilities under skilful selection. Seed may be sown in April and the resulting plants thinned to 8 ins. apart each way. They are useful for massing and carpeting or for the rock garden.

Charieis heterophylla (Syns. *C. caerulea, C. Neesii,* and *C. pilosella,* also *Kaulfussia amelloides*).—This bears Daisy-like flowers on slender stalks throughout the summer. There are various colours available, such as white, blue, violet, and crimson. Height, 6 ins.

C. H. C.

CAPE BULBS.

The chief of these are Crinum, Galtonia, Gladiolus, Ixia, Lachenalia, Lapeyrousia, Sparaxis, Tritonia, and Watsonia. The majority of these are of easy culture, and notes on this will be found under the above names in their proper places in this work.

CAPE FIGWORT (*Phygelius capensis.* Nat. Ord. Scrophulariaceæ).—This, as many gardeners know, is a most attractive hardy perennial subject for the herbaceous or mixed border, bearing bright scarlet flowers from August to September, and growing 3–4 ft. high. It succeeds best in the hottest, sunniest, and driest portion of the border, and then will give a wealth of bloom. In cold, wet, and exposed districts some winter protection such as a mound of ashes or cocoanut fibre refuse will be advisable. Otherwise it may be treated in much the same way as any other hardy perennial. Propagation is quite a simple matter: seeds may be sown in the spring, cuttings inserted in a rough frame in the summer, or the plants may be divided in November or March, which latter month is the best period for planting.

CAPE GOOSEBERRY (*Physalis peruviana*).—See *PHYSALIS.*

CAPE LILY.—See *CRINUM.*

CAPE POND FLOWER.—See *APONOGETON* and *WATER GARDEN : PLANTS FOR THE.*

CAPE PRIMROSE.—See *STREPTOCARPUS.*

CAPE SHAMROCK (*Oxalis purpurata*). See *OXALIS.*

CAPE STOCK (*Heliophila.* Nat. Ord. Cruciferæ).—This family includes several half-hardy annuals

which are easily raised from seeds sown in gentle heat in spring, or from an outdoor sowing made at the end of March or in April. They are low growing, and do not last long when they have reached the flowering stage. The best species are *Heliophila amplexicaulis* (white and purple); *H. crithmifolia* (violet); *H. pilosa* (Syn. *H. stricta*), blue; and *H. p. incisa* (Syn. *H. araboides*), blue. These bloom in late June, and average 6–9 ins. in height.

CAPER SPURGE (*Euphorbia Lathyrus*).—See *EUPHORBIA*.

CAPERS.—See *EUPHORBIA*.

CAPNORCHIS.—Now included in the genus *DICENTRA*.

CAPOLLIN (*Prunus serotina salicifolia*).—See *TREES*.

CAPON'S-TAIL GRASS (*Valeriana pyrenaica*).—See *VALERIANA*.

CAPSELLA (Nat. Ord. Cruciferæ). This is a genus of troublesome annual weeds of no value whatever in the garden, but which are responsible by their presence for the spreading of Clubroot in cabbages, which disease is fully dealt with in our article on *DISEASES OF PLANTS*. The best known species is *C. Bursa-pastoris*, or SHEPHERD'S PURSE, described under the latter name, with methods of control, in our article on *WEEDS*.

CAPSICUM.—See *SALAD PLANTS*.

CAPSID BUGS.—See under CUCKOO SPIT in *INSECT PESTS*.

CARAGANA.—For the best species see *SHRUBS*.

CARAWAY.—See *CARUM* and *MEDICINAL HERBS*.

CARBIDE OF CALCIUM.—See CALCIUM CARBIDE in *LIME COMPOUNDS*.

CARBIDE REFUSE.—See *SOIL FUMIGATING*, and under CALCIUM CARBIDE in *LIME COMPOUNDS*.

CARBOHYDRATES.—See under CARBON in *CHEMISTRY FOR GARDENERS*.

CARBOLIC ACID.—See *ACIDS*, *SOIL FUMIGATING*, and *WEED KILLERS*.

CARBON. — A few notes on this essential element will be found in *CHEMISTRY FOR GARDENERS*.

CARBON ASSIMILATION.—See under FOOD SYNTHESIS in *PLANT PHYSIOLOGY*.

CARBON BI-SULPHIDE.—See *SOIL FUMIGATING*.

CARBON DI-SULPHIDE.—The same as CARBON BI-SULPHIDE.

CARBONATE OF AMMONIA.—The same as AMMONIUM CARBONATE. See *AMMONIA AND AMMONIUM COMPOUNDS*.

CARBONATE OF CALCIUM. — See CALCIUM CARBONATE in *LIME COMPOUNDS*.

CARBONATE OF LIME.—The same as CARBONATE OF CALCIUM.

CARBONATE OF MAGNESIA.—The same as MAGNESIUM CARBONATE, to which a reference is made in *MAGNESIA AND MAGNESIUM COMPOUNDS*.

CARBONATE OF POTASH. — See POTASSIUM CARBONATE in *POTASH AND POTASSIUM COMPOUNDS*.

CARBONATE OF SODA.—See SODIUM CARBONATE in *SODA AND SODIUM COMPOUNDS*.

CARBONIC ACID.—See *ACIDS: THEIR USES IN HORTICULTURE*.

CARDAMINE (BITTER CRESS. Nat. Ord. Cruciferæ).—This genus now includes that previously known as *Dentaria*, and although a comparatively large one is quite unimportant since there are many better subjects. It chiefly consists of hardy annuals, hardy herbaceous perennials, and hardy rock plants. The first and the last sections are excluded from this work, as they are beyond its present scope.

The hardy perennial species are useful for the ordinary borders and for shrub borders. They will thrive in moist rich soil in a sunny site. They are not hard to propagate by division of the roots in the spring or autumn, at which times they may be successfully planted. We recommend the following:—

Cardamine bulbifera (CORAL ROOT).

This bears purple flowers in May, and grows about 18 ins. high.

C. diphylla (TOOTH CRESS).—This bears purple or purple and white flowers in April and May. Its height is 1 ft.

C. enneaphylla.—This bears pretty yellow flowers from May to June, and grows 12 ins. high.

C. maxima.—This sort bears pale blue-purple flowers in May, and grows about 2 ft. high.

C. pinnata.—This is similar to the above, but only grows a little over 12 ins. high.

C. pratensis (LADY'S SMOCK).—This is a common marsh plant hardly worth growing in the borders, though the double form *flore pleno* is quite attractive. A very moist site is required for both these pale purple spring blooming subjects and also for the white form *alba.* All grow about 12 ins. high.

C. Waldsteinii (Syn. *Dentaria trifolia*).—This is a pretty white May flowering subject for the front of the borders, growing about 12 ins. high.

CARDARIA.—Now included in the genus *LEPIDIUM.*

CARDOON (*Cynara Cardunculus.* Nat. Ord. Compositæ).—Although these enjoy little popularity among English vegetable growers, they are largely grown and appreciated abroad; but owing to the amount of room and considerable after attention required, they are not recommended to owners of small gardens or others who wish to grow the most profitable crops. The plants can be raised and treated exactly as advised under *CELERY.* When fully grown and perfectly blanched, they are used in soups, or as a boiled vegetable.

See also *CYNARA.*

CARDUUS (THISTLE. Nat. Ord. Compositæ).—This was once a very large genus, but at the present time most of the species are included by botanists in other genera, notably in *CNICUS,* on which a separate article appears. The species still retained are apt to be weedy, and should not be grown in the choicest borders, though they are useful in the shrub borders or the wild garden.

What to Grow.—The following species may be mentioned:—

Carduus arvensis.—This, the weed known as CORN THISTLE, is now known as *Cnicus arvensis.* It is referred to in our notes on *CNICUS.*

C. crispus.—This is a purple-flowered biennial species blooming in July, and growing about half a yard in height.

C. nutans (MUSK THISTLE).—This biennial species is probably the most popular of all with its purplish flowers in July, on plants 2 ft. in height.

C. tenuiflorus (Syn. *C. pycnocephalus*).—This, the SLENDER-FLOWERED THISTLE, is a perennial bearing purple flowers from July onwards, and growing 3–4 ft. in height.

See also HOLY THISTLE in *MEDICINAL HERBS.*

CAREX (SEDGE. Nat. Ord. Cyperaceæ).—This is a large genus of hardy perennial and half-hardy or greenhouse grasses or sedges of very little importance in the garden. *C. pendula* is a good plant for the water garden. Other sorts chiefly suitable for the wild garden include *C. flava,* the MARSH HEDGEHOG GRASS; *C. glauca,* the CARNATION GRASS; *C. hirta,* the HAMMER SEDGE; *C. paniculata,* the HASSOCK GRASS; and *C. Pseudocyperus,* the BASTARD CYPERUS. All are of the easiest culture and spread quickly when once planted. This genus does not contain the SWEET SEDGE described in our article on *MEDICINAL HERBS.* That belongs to *ACORUS,* which see.

CARNATION. — (*Dianthus Caryophyllus*).—See *DIANTHUS.*

CARNATION GRASS (*Carex glauca*).—See *CAREX.*

CARNATION MAGGOT.—See *INSECT PESTS.*

CARNATION : The Malmaison.

Among the several types of Carnations, the Malmaison is the most handsome and noble flower. It has been largely grown for a number of years as a summer flowering plant, and it is of a comparatively recent date that perpetual flowering varieties have been introduced. These can be had in bloom far more easily during the winter than the older type of plant. It is of the latter, however, that this article deals with in the first place.

In common with the other kinds of Carnations the Malmaison requires a light house, with a cool buoyant atmosphere, if it is to be grown to perfection.

Care of Layers.—It is most easily propagated by layering in July and August, and the last week in July is an ideal time. Select plants that are free from any trace of disease for this purpose, and preferably those that have been placed outside in an open position for about ten days after flowering. Layer the plants in a frame, in the usual way described in our article on *PROPAGATION OF PLANTS.*

After layering, water well, and keep the frame close until roots commence to form; shade from the sun, and give the layers a spray over with the syringe twice daily. If the weather is very hot, it is admissible to allow an inch or two of air at the top of the frame, and when the roots form, increase this, until after a few days the lights can be removed entirely. Sever the layers in the usual way, lift with a small hand fork, and pot separately in 60-sized pots. Place them in a frame, and keep fairly close for a few days, but then give more air, and shade from bright sunshine. When the plants are nicely rooted shift them into 32-sized pots, and see that they are moist at the roots before this is done. A compost consisting of three parts good fibrous loam, and one part flaky leaf-soil, with the addition of a little old mortar rubble, and sufficient wood ashes or crushed charcoal and silver sand to render the soil free and porous, suits the plants well. The inclusion of a little old soot will be beneficial. Plenty of crocks are needed. Watering will require great care, as Malmaisons resent much moisture at the roots, especially during winter.

Winter Treatment.—The best place for the plants during the winter is a span-roof house, where sufficient heat can be turned on to exclude frost. A night temperature of 45° F. is sufficient, and in very cold weather 40° F. would be better. Admit all the air possible on favourable occasions, and when the weather is damp and foggy, just an inch or two of air with a little warmth in the pipes will be the best means of keeping the atmosphere dry and buoyant. Under such conditions the rust disease will not attack the plants. Greenfly is easily kept in check by an occasional fumigation.

After the turn of the year the plants will show signs of renewed growth, and occasional applications of soot water will prove beneficial. When the flower spikes commence to develop a light dressing of some Carnation manure may be given at intervals with good results, and is generally to be preferred to liquid farmyard manure, although the latter may be used occasionally if properly diluted.

Plants that were layered late in the season, and passed the winter

in small pots, should be potted on early in March. Give stakes when necessary, and disbud the growths carefully to obtain fine flowers.

When the blooms commence to show colour it is beneficial to shade them from strong sunshine, or they will not last fresh and bright for so long a period.

Treatment after Blooming.—After the flowers are over, select the best plants to grow on for another year. Those with the most healthy and vigorous growths are the ones to retain. Pot these into 9–10-inch pots; vigorous varieties of the Princess of Wales type make fine specimens in the latter-sized pots. The compost already recommended should be used, but a little Carnation manure can be added with advantage. Make sure that the plants are moist at the roots in the first place, and pot firmly. Tie out each growth to a separate cane, and grow the plants on in a light, airy position. The treatment of these plants during the autumn and winter is similar to that already described.

Varieties.—These are numerous, but when purchasing take care to get the plants from a nurseryman who has a thoroughly healthy stock.

Duchess of Westminster—a good sort for early flowering—is a lovely rose-salmon-pink. The blooms are not so large as some, but the perfume is glorious.

Lady Coventry is a handsome rich red, and is a vigorous grower.

Lord Rosebery is rather similar in growth and size of flowers to *Duchess of Westminster*, while the blooms are a telling shade of cardinal red.

Maggie Hodgson is a rich deep crimson.

Nautilus is a pale pink, and *Nell Gwynne* a good white variety.

Princess of Wales is one of the finest varieties, and it has a very pleasing perfume.

Perpetual Flowering Malmaisons.—These flowers have undoubtedly come to stay, and are increasing in popularity owing to their extended period of flowering. Their cultivation and general treatment is on the same lines as the Perpetual Flowering Carnations, and readers are referred to the article on the same. It is not advisable to stop the growths more than once, or the flowering period is too long delayed.

There are several good varieties, and of these *Mrs C. F. Raphael* is one of the best. The blooms are a lovely shade of cherry red, and are produced on tall erect stems. *Marmion* is a very pleasing variety; the blooms are a soft shade of pink, overlaid with cream markings. This variety has been grown for some years, and is very popular. *Majestic* and *Terrific* are newer varieties, both red shades, and there are likely to be hosts of other fine novelties in the near future.—J. G.

CARNATION: The Perpetual Border.—This is a new section, resembling the ordinary Borders, but flowering out of doors throughout the season up to September or October. The treatment is the same as for the ordinary Border varieties. Propagation may be effected by layers of non-flowering shoots, by cuttings, and also by seed.

Varieties.—The following are the best at present:—

Brilliant.—White flowers, edged and flaked with purplish crimson.

Highland Lassie.—White flowers, flaked with red.

Rosalind.—Yellow flowers, heavily marked with red.

Sussex Pink.—Delicate flesh-pink flowers.—W. J. C.

CARNATION: The Perpetual Flowering.—Few flowers are so much appreciated or so useful for

decorative purposes as Perpetual Flowering Carnations. The plants can be had in bloom during the whole year with ordinary care, but it is chiefly during the winter months that they are most valued. They are among the most economical greenhouse plants, owing to the little heat that is necessary for them, consequently they are ideal flowers for the amateur gardener.

Essential Details. — There are several essential points to observe if the grower wishes to meet with a full measure of success. The foremost among these is the maintenance of a fresh, buoyant atmosphere, combined with the maximum amount of light during the dull months of the year. A span-roof house is the best for the plants, but it is a matter of small consequence whether the house runs north and south, or east and west, if it is in an absolutely open position.

Provision should be made for abundant ventilation in hot, sunny weather. A house fitted with a central stage, and staging around the sides, is the best, when it can be managed.

Propagation.—This is effected by means of cuttings. The best time to insert them is from November until February. If the plants are rooted too late in the season, they do not become well-grown specimens before winter. The best plan is to place a small propagating frame on the stage of a greenhouse with a temperature of about 50° F., with a few degrees more bottom heat if possible. Cover the bottom of the frame with 3 ins. of fine sand, and make this moderately firm. The cuttings should be selected from plants that are healthy and free from any kind of insect pest. Shoots about 4 ins. in length from the central parts of the stems make the best cuttings. They are then slipped off and inserted firmly in the usual way, as is described under CUTTINGS in the article on *PROPAGATION OF PLANTS*, after which a good watering is given. Little more water should be needed until the cuttings take root, but if there are signs of dryness, give more water. Remove the light from the frame every morning for about an hour, and dry the inside of the glass. Otherwise no air is needed until the cuttings are rooted, but then it should be gradually increased until the frame-light can be left off entirely.

Potting On.—After about three days of this last treatment, when the cuttings are nicely rooted, take them up carefully and pot them separately in 2-inch pots. For this use fine soil consisting of three parts loam, with the remainder made up of silver sand and good leaf-soil. Grow the plants on in the same temperature, and water them after potting, but later on only give water when the soil becomes dry. When the pots are full of roots transfer the plants to large 60's. A similar compost is advised here, but a little fine wood ash may be added with advantage. See our article on *POTTING* for general hints on this matter.

Continue to grow the plants on in a position near the light to encourage sturdy growth, and do not allow the temperature of the house to exceed 55° F. When growth has advanced a little, pinch out the tops of the plants to induce the formation of side-shoots; but do not do this too early, as some varieties produce side-growths naturally. The best time to do this stopping is during the early morning, and if the growths are bent sideways they will snap off readily. About five pairs of leaves should be left when this is done.

The most forward plants will be ready to move into 48-sized pots in March. Use a compost of three parts good fibrous loam and one part flaky leaf-soil, with the addition of some wood ashes, old mortar rubble, and a little silver sand. If the loam is rather heavy, add a little more opening material to the compost. Pot firmly. Grow the plants on under similar conditions, but give more air on fine days. In May, remove them to a cold frame, and when they are sufficiently rooted shift them into pots known as 24's, when a similar compost should be used. It will be beneficial, however, to add a little of some approved Carnation manure at the rate of a 5-inch potful to each bushel of the compost. Bone-meal and soot are good substitutes for a special manure. Water carefully after potting, and on bright days give the plants a light spray over with a syringe during the late afternoon, but in time for the foliage to become dry before night.

Stake and tie the plants as support is needed. The growths should be stopped a second time, and although the period for doing this varies with the variety and district, the middle of July is usually late enough. Varieties such as *Carola*, *Baroness de Brienen*, and the Perpetual Flowering Malmaisons are most satisfactory if only stopped once. Plants rooted after the New Year should be treated in the same way ; but in this case it is preferable to pot them in 32's direct from the 60's, and allow them to flower in that sized pot.

Stand the plants in an open position from June until September, and give them weak soot water at the root every three days when nicely rooted. It is also beneficial to spray them lightly overhead with clear soot water in the afternoon after bright days. It is a good plan to have a wooden framework over the plants, so that frame-lights can be placed over the top in case of heavy rain-storms.

Housing the Plants. — The end of September or early in October is the best time to put the plants under glass. When this is done, examine them carefully for any sign of disease or insect pests, and remove any decayed foliage at the base. Fumigate the house, when full, with nicotine, and repeat this at intervals to guard against green-fly. Ventilate freely on all favourable occasions, and only use fire heat when necessary to expel excessive moisture in the atmosphere, and to prevent the temperature from falling too low when frosts threaten. Too much moisture encourages the rust disease. If any of the leaves are found to be attacked by this, the best plan is to cut them off and burn them. A night temperature of 50° F. suits the plants well in winter, but no harm will follow if it falls a few degrees lower on frosty nights. Avoid overheating the pipes at any time, and endeavour to keep a little air on the top of the house when it can be done without lowering the temperature too much.

After-Treatment.—Watering needs especial care, and on no account must the plants be kept too wet at the roots. Attend to this work during the morning, and avoid spilling water about the house in damp weather.

After the plants are settled in their flowering quarters, they will derive benefit from judicious feeding with a little Carnation manure, and this may be followed up at intervals, except for a few weeks at midwinter, and until growth becomes more active such feeding should be given sparingly.

Disbudding requires careful attention at all times if fine blooms are expected. Remove the side-shoots gradually, for if all the flower-buds are taken off a stem at the same time the bloom will probably be blind or malformed. Beyond keeping the shoots neatly tied for support as growth advances, there is little further attention needed by the plants.

Open-Air Culture. — Perpetual Flowering Carnations are very suitable to plant in the open garden, where they can be had in full bloom from May until October. Plants that have flowered in the greenhouse during the winter give good results treated in this way. The best specimens for the purpose are those that are well set with flower-buds at planting time, and if they are kept neatly tied and have the dead blooms removed as these appear, they will make a very attractive flower-bed throughout the summer. Cuttings inserted in a shady frame during August make nice-sized plants to put out towards the end of April. They can also be rooted successfully in the open garden, and will pass through the winter safely in most districts with just a little protection during severe weather. Owing to the length of time they continue to flower, they are to be preferred to Border Carnations for an outdoor display.

[Insect Pests and Diseases, with their remedies, will be found separately dealt with in our articles on those subjects.—EDITOR.]

Varieties. — These are very numerous, and new ones of merit are continually being introduced. Those mentioned include sorts whose merits entitle them to be generally grown:—

Baroness de Brienen is an unusually fine flower. The blooms are large, and of a pleasing salmon-pink shade. as

Benora also merits inclusion, its fine white flowers with pink markings are very telling and distinct in appearance.

Britannia still deserves inclusion if a good stock of it is obtained, and it is a fine variety for summer bedding.

Carola is a delightful crimson of exceptional size. This variety is well worth every care to grow it to perfection.

Enchantress, though an older sort, still deserves a place where pale pink blooms are appreciated, and it is in every way a grand variety when a good stock of it is obtained.

Lady Northcliffe is a lovely salmon-pink, and is very fine when at its best.

Mary Allwood is one of the finest of modern Carnations. The blooms are of good size, exceptionally well formed, and are produced on sturdy, erect stems. The colour is a pleasing shade of cardinal-pink.

Mikado, frequently described as a glistening heliotrope, is well worth growing, and is often in great demand.

Mrs C. W. Ward is a healthy and productive variety with cerise-pink flowers; a good market Carnation.

Rose Enchantress is a cerise-pink form of *Enchantress*.

St Nicholas is a showy scarlet variety.

Salmon Enchantress is a welcome addition to any collection; the blooms are a good salmon-pink, but not over freely produced.

Scarlet Glow is one of the best reds, and when well grown is very fine.

Snowstorm and *Wivelsfield White* are useful sorts, with flowers of a looser build.

Sunstar is an attractive flower, with its yellow blossoms just marked with pink.

Triumph is a free-flowering crimson variety of especial merit.

White Wonder is one of the best white sorts, the blooms being of perfect shape and good size.

J. G.

NEW VARIETIES.

Some of the best are :—

Alice.—Blush pink flowers.

Brilliant.—Glowing scarlet flowers.

Countess of Pembroke.—Art red flowers.

Countess of Wilton.—Terra-cotta red flowers.

Destiny.—Soft cerise flowers with a rich scent.

Eastern Maid.—Old rose flowers, suffused with pale heliotrope.

Edward Page.—Carmine-rose flowers.

Good Cheer.—Deep pink flowers.

Grizel.—Bright purple flowers.

Louvain.—Cerise-salmon flowers.

Malcolm.—Salmon-red flowers, very freely produced.

Marion Wilson.—Yellow flowers flaked with scarlet.

Mrs Douty.—Velvety crimson flowers.

Mrs G. Lloyd Wigg.—Pure white flowers. A sport from *R. F. Felton.*

Mrs Mackay Edgar.—Rosy-pink flowers.

Nora West.—Salmon-pink flowers.

Pink Sensation.—Shell-pink flowers.

Red Benora.—Rich red flowers. A sport from *Benora.*

Red Cheney.—Brick-red flowers. A sport from *Mrs B. P. Cheney.*

Red Ensign.—Light orange-scarlet flowers.

Rose Sensation.—Very large carmine-rose flowers.

Saffron.—Clear yellow flowers. A sport from *Sunstar.*

Scarlet Carola.—A bright scarlet form of *Carola.*

The Major.—Bright chocolate-red flowers.

Winter Glow.—Scarlet-cerise flowers.

Wivelsfield White.—Pure white flowers with a strong scent.—W. J. C.

CARNATION RUST.—See *DISEASES OF PLANTS.*

CARNATIONS (*Dianthus Caryophyllus.* Nat. Ord. Caryophyllaceæ). **Cultivation in the Border.**—Damp is the greatest enemy of the Carnation; to avoid it great care must be taken in preparing the soil. The ground should be trenched, or bastard trenched, at least a fortnight before planting is to take place, and then arched up and trodden very firm. To light soil add well-rotted cow manure or farmyard manure. Stable manure is best for clay soils, to which sand or mortar rubble should also be added. The roots of the plants should on no account be allowed to come in contact with fresh manure. The late Mr James Douglas was a most strenuous opponent of over-manuring; he attributed weakness of constitution and liability to disease mainly to the unwholesomely rich soil used by most of the carnation growers of the nineteenth century.

Carnation layers should be planted out in autumn. They may also be potted up then, kept in a frame during the winter, and planted out in March. Autumn planting produces finer stock, as well as a larger number of blossoms, and is to be recommended except when soil is apt to become water-logged. Plant at least 15 ins. apart, and make the soil very firm round the roots and stem, avoiding any depression which would hold water at the collar. All dead and diseased leaves should be removed and burnt; otherwise there is little to be done during winter for plants in the border.

In April and May, when the plants begin to send up flower-stems, these

must be tied to stakes (thin bamboos about 4 ft. long are the best) with pliable raffia or bast. Cross the tie between the stake and stem so as to form the figure 8. If the ground be very dry, watering may be necessary in May, but it should be postponed as long as possible. Mulching or hoeing conserve the moisture deep in the soil; but when the time comes that watering can no longer be postponed, then give a thorough soaking one day, or perhaps two days running, hoe the next day, but do not water again for three or four days at least.

Flower-stems must be disbudded rigorously if it is intended to exhibit. Even for ordinary purposes varieties which produce half a dozen buds close together at the top of the stem require to be disbudded. But an increasing number of modern varieties produce blooms at even distances down the stem, and these require little or no disbudding except for exhibition.

Pot Culture.—Carnations for exhibition should if possible be flowered in pots in an unheated greenhouse. This procedure renders it easier to protect them from insect pests, and makes it possible to retard or accelerate the time of flowering, as may be required by the date of the show. Also plants grown in pots tend to produce weaker foliage and finer blossoms than those growing in the border.

Layers should be potted up in autumn, one plant being placed in a 3-inch pot, two plants in a 3½-inch pot. Ordinary potting soil suffices, provided it is porous; an ideal mixture may be composed of 4 parts loam, 1 part leaf-mould, 1 part manure, ½ part ground oyster shells or coarse sand. Both leaf-mould and manure must be thoroughly decayed. The pots should then be placed in a cold greenhouse, or frame, to which, after the first week, as much air as possible should be admitted; whilst watering should be most sparing, and care taken not to wet the leaves.

In March the plants should be transferred to the flowering-pots; two plants in an 8-inch pot is best. They should then be stood out of doors on dry ashes. As the plants make larger roots more and more water must be given. In hot weather much care must be exercised to prevent the roots becoming dry; on the other hand, in cool weather the soil should not be too wet. Very firm potting is absolutely necessary.

Care must be taken to prevent ants or other insects entering the pots. Staking must be attended to as directed under heading CULTIVATION IN THE BORDER. For exhibition, disbud to one bloom before the buds show colour. In any case plants in pots require disbudding, as they cannot satisfactorily produce as many blooms as large plants deeply rooted in the open ground. I advise against applying chemical manures, but from the middle of June weak cow or sheep liquid manure may be given in small quantities twice a week, *after* watering.

As soon as flower-buds begin to show colour the pots should be moved from the open air into an unheated greenhouse, and elastic bands should be placed round the buds to guard against the possibility of split calyces.

Propagation.—New varieties of Border Carnations are raised from seed, but existing varieties are increased by layering, which should be proceeded with as early in the summer as possible. June is not too early. Layering is dealt with under *PROPAGATION OF PLANTS*. Equal quantities of loam and leaf-

mould, and a little thoroughly decayed manure, with ground oyster shells or coarse sand, make a suitable compost. For pegging down various makes of layering pins are sold, or ladies' hairpins can be used.

If possible, layer in showery weather in the case of plants growing out of doors. In dry weather layers require watering twice a day through a fine rose for the first few weeks, and after that once a day. In the case of shoots growing high up the stem the compost has to be much raised, and naturally becomes dry sooner than when on the ground level.

At least two months (longer if possible) should elapse between layering and transplanting. Then the shoot layered should be severed from the parent plant with a sharp knife, and a day or two later should be transplanted to the ground, prepared as advised under heading CULTIVATION IN THE BORDER; or potted up and placed in a cold greenhouse, or frame.

Plants growing in pots are usually layered in the pots; some growers prefer to turn them out of the pots into the border when the flowering season is over, and layer them there. This practice has the disadvantage of deferring layering until August.

SEEDLINGS.—Sow in seed pans in the spring, place in moderate heat, or under a frame or hand-light. After germination remove to a cold house; prick out as soon as the seed leaves are fully developed. Plant in open ground in July and subsequent months, 18 ins. apart.

Varieties.—Border Carnations are being rapidly improved at the present time; each year sees the introduction of novelties which are superior to older varieties. Consequently any list of named varieties becomes speedily out of date. The following list is arranged in classes as defined by the National Carnation and Picotee Society, and the order is that of merit according to my judgment:—

SELFS.—"These should be of one decided colour. If the flower be in any way shaded, striped, or spotted, it is at once disqualified for Self Class."

Dark Red and Maroon Selfs.—Gordon Douglas, E. K. Wakeford, Mrs George Marshall, Bookham Clove, Henry Brett of New Zealand, The King, Hercules, Surrey Clove, Induna.

White Selfs.—Bookham White, Elaine, Purity, Prairie Belle, Farthest North, Sir Galahad, Trojan, Kate Nickleby.

Yellow Selfs.—Daffodil, Glamour, Sunbeam, Solfaterre, Cecilia.

Buff and Terra-cotta Selfs.—Elizabeth Shiffner, Dora Blick, Mrs Griffith Jones, Mrs G. A. Reynolds, Robert Bruce, Mrs Robert Morton.

Red and Scarlet Selfs.—Fujiyama, Fiery Cross, Miss Willmott, Cardinal, General French, Firefly Deloraine, Glowworm, Brigadier, Veldtfire.

Pink and Rose Selfs.—Mrs Percy Smith, Rosetta, Salmonea, Annie Laurie, Rosy Morn, My Clove, Wyatt, Peach Blossom.

Wine-coloured Selfs.—Miss Rose Josephs, Ziska, Opalesce.

Grey or Lavender Selfs.—The Grey Douglas, Ellen Douglas, Evangeline, Greyhound.

Purple Selfs.—Purple Emperor, Cassius, Irma, Dick Swiveller, Royal Velvet.

FANCIES.—"These are best defined as varieties that cannot be admitted into any other classes. They should be large, and their chief excellence lies in their quality of petal and brilliancy of colouring. The ground colour may be yellow, apricot, or white, striped, flaked, or spotted with various colours."

Yellow Ground Fancies.—Pasquin,

Lord Steyne, Lieut. Shackleton, Skirmisher, J. J. Keen, Virginia, The Dawn, Centurion, Sweet Anne Page, John Ridd, Sam Weller, Linkman, Queen Eleanor, Becky Sharp.

White Ground Fancies.—Othello, Mrs G. D. Murray, Daisy Walker, Fair Ellen, Mrs P. W. Owen, Lord Kitchener, Betty, Montrose, George Robey.

Nondescript Fancies.—Mrs Andrew Brotherstone, Caprice, Hecla, Banshee.

BIZARRES AND FLAKES.—"These are White Ground Carnations. The Bizarre must have on every petal stripes of two different colours. In the Flake these stripes must be of one and the same colour. In both classes the stripes should be clear and well defined: broad on the edge of the petal and gradually diminishing until they sink into the heart of the flower."

Bizarres.—Armourer, Supreme, Remus, Carbine, Black Diamond, Arthur, Amersham, Zebra, Sonata, William Skirving.

Flakes.—Gordon Lewis, Kobe, John Peel, Torchlight, Recorder, Rose Noble, Dick Swiveller.

YELLOW GROUND PICOTEES.—"These should have a clear yellow ground (not apricot or buff). The petals should be firm, flat, and smooth, and their edge well rounded and free from fimbriation. The line of colour on the edges of the petals may be light, medium, or heavy, but should be of one continuous colour and entirely confined to the edge; any break in the margin or a running down of the marginal colour into the petal being esteemed a grave fault."

Yellow Ground Picotees.—Margaret Lennox, Onward, Mrs J. J. Keen, Togo, Eclipse, Professor Burstall, Niel Kenyon, Her Majesty, Santa Claus.

WHITE GROUND PICOTEES.—"Saving in the colour of the ground, the qualities required in this class are identical with those laid down for the Yellow Ground Picotee."

White Ground Picotees.—Perfection, Fair Maiden, Clytie, John Smith, Lavinia, Amy Robsart.

S. M. K.

NEW VARIETIES.

Some of the best are:—

Albion.—Pure white large flowers.

Cleopatra.—Large fragrant ruby-heliotrope flowers.

Mrs F. G. Bealing.—Fragrant deep salmon flowers.

Sweet Anne Page.—Yellow flowers splashed with lavender.

CARNIVOROUS SLUGS.—See *INSECT PESTS.*

CAROLINA ALLSPICE (*Calycanthus floridus*).—See *SHRUBS.*

CARPENTARIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

CARPENTER'S LEAF.—A name sometimes applied to *Galax aphylla.*

CARPET BEDDING.

At the present day carpet bedding is not much practised, though in the seventies and eighties of last century it was carried to a great extent and perfection, especially in the public parks of the British Isles; but it was also well done in private establishments on a smaller scale. The work was carried out with flowering plants, though they were not allowed to bloom as a rule, the flowers being pinched out to prevent it and to keep the plants to a dwarf and uniform height, according to their situation in the beds. Plants of various heights were employed, but the system of pinching reduced them to a common or desired level. The effects were obtained by making panelled beds, often of intricate design, and planting the various panels, with subjects having red, purple, crimson, rose, yellow, golden,

white, grey, or variegated leaves. The general effect was splendid or gorgeous to a degree, proportionate to the boldness of the design, the wealth of plants employed, and the neatness of the whole. This was effected by using hundreds of thousands of small plants to cover the ground soon after they were established. Owing to the large numbers employed, and the work of pinching every two or three weeks, the expense was great and the art gradually got abandoned as the novelty of this style of gardening wore off. In many gardens a large number of hardy plants were employed; but as many tender ones formed a large proportion of the best designs, stock had to be kept in hot-houses during winter, and these had to be propagated extensively in February, March, and April in properly heated houses or propagating pits.

Single beds of oblong, oval, circular, square, and other outlines were cut out in grass alongside the principal walks in parks and gardens, in full exposure to sunshine to keep the plants dwarf, sturdy, and highly coloured. Geometrical beds in greater or less number were also laid out in symmetrical designs in the more ambitious flights of the art. Each bed was laid out in a series of panels, numbering four, six, eight, or some other number that would enable two panels at least to be planted with the same variety of plant. If there were only three leading panels in a bed, all had to be planted alike, but with four, two could be filled with one plant, and two with another, and so on for the whole design. Every two panels thus planted had to be opposite one another, not side by side. Most beds were level, but others, especially circular ones, had an elevated table in the centre, and a smaller and still higher one within it, both being level on the top to prevent rain or water from running off. The sloping sides of these tables were often puddled and planted with appropriate subjects to hold them up.

The beds were first dug, levelled, or variously built up, and then raked quite smooth, after which the design could be drawn upon them for the guidance of the planters. The outlines could then be planted with suitable subjects to make dividing lines, and the panels were then filled in with their appropriate subjects. Every circular bed had a central or dot plant, and every panel might have a centre of its own, the plants used being generally different from those in the centre of the bed. Large panels near the outside of the bed were often planted with something green, such as *Herniaria glabra, Mentha Pulegium gibraltarica,* Mossy Saxifrages, *Sedum lydium,* and *Veronica repens,* all hardy; but this groundwork, as it was called, might be filled with tender plants, such as the Alternantheras, Lobelias, *Mesembryanthemum cordifolium variegatum, Sedum sarmentosum variegatum, Tagetes signata pumila,* and others. Yellow panels could be planted with *Alternanthera paronychioides aurea, Sagina glabra pilifera aurea, Stellaria graminea aurea*; purple ones with *Alternanthera amabilis, A. amoena, A. tricolor, A. versicolor, Iresine Lindeni,* or *Oxalis corniculata atropurpurea*; and grey or white ones with *Antennaria dioica tomentosa, Calocephalus Brownii, Cerastium tomentosum,* and encrusted Saxifrages. Dividing lines between panels were planted with *Coleus Verschaffeltii, Iresine Herbstii, I. H. aureo-reticulata, I. Lindeni, Kleinia Haworthii, K. repens,* and *Perilla nankinensis.* Edging plants were *Echeveria secunda glauca,* Golden

Feather, blue, white, or purple Lobelias, and Mossy Saxifrages. The Lobelias were allowed to bloom. The best plants for steeply sloping edges were *Echeveria secunda glauca*, *Sempervivum calcareum*, and *S. tabulaeforme*.

The centre of circular beds mostly or always had a tall or large plant, either light and graceful, or a massive succulent. Oblong or oval beds usually had a series of large centre plants along the middle, at regular intervals, according to the panels. Various other panels also had centre plants, but they were smaller and subservient to the centre of the bed. Large panels usually had dot plants at regular intervals. The size to which plants may grow in the course of years has no bearing on the situation, and never has had any. The present-day planter, like those in the past, has merely to avoid plants that will grow too tall in the course of a single season for any given bed.

PLANTS FOR CARPET BEDDING.

Alternanthera amabilis, A. amoena, A. paronychioides, A. p. aurea, A. p. magnifica, A. p. major, A. tricolor, and *A. versicolor.*
Antennaria dioica tomentosa.
Calocephalus Brownii (Syn. *Leucophyta Brownii*).
Cerastium tomentosum.
Chrysanthemum Parthenium aureum, and *C. P. selaginoides.*
Coleus Verschaffeltii.
Echeveria secunda glauca.
Herniaria glabra.
Iresine Herbstii, I. H. aureo-reticulata, and *I. Lindeni.*
Kleinia Haworthii (Syn. *K. tomentosa*), *K. repens.*
Kochia scoparia trichophylla.
Lobelia Erinus, in blue, white, and purple varieties.
Mentha Pulegium gibraltarica.
Mesembryanthemum cordifolium variegatum.
Oxalis corniculata atropurpurea (Syn. *O. c. rubra*).
Perilla nankinensis.
Sagina glabra pilifera and *S. g. pilifera aurea.*
Saxifraga Aizoon, S. caespitosa, S. Cotyledon, S. decipiens, S. Hostii, S. hypnoides, or any of their varieties.
Sedum hispanicum (Syn. *S. glaucum*), *S. lydium, S. sarmentosum variegatum.*
Sempervivum arachnoideum, S. calcareum, S. globiferum, S. Laggeri, S. montanum, S. tabulaeforme, S. Tectorum, S. tortuosum variegatum
Stellaria graminea aurea.
Tagetes signata pumila.
Veronica repens.

CENTRE AND DOT PLANTS.

Aloe mitriformis, A. Serra.
Aralia Veitchii, A. V. gracillima.
Centaurea gymnocarpa, C. ragusina.
Cereus, any plants of suitable size.
Chlorophytum elatum variegatum.
Cordyline australis, C. a. Doucettii, and other varieties.
Cotyledon bracteosa, C. rosea.
Dracaena concinna, D. rubra.
Echeveria gibbiflora metallica, E. glauco-metallica.
Gasteria verrucosa, etc.
Kochia scoparia trichophylla.
Mamillaria, any plants of suitable size.
Ophiopogon Jaburan variegatus.
Opuntia in plants of suitable size.
Pandanus Veitchii.
Sempervivum arboreum, S. canariense, S. cuneatum, S. Haworthii.
Yucca aloifolia, Y. a. tricolor, Y. a. variegata, Y. filamentosa, Y. f. variegata.—J. F.

CARPET JUNIPER (*Juniperus Sabina prostrata*).—See *TREES.*

CARPETING, ROCK PLANTS FOR.—See ROCK PLANTS FOR CARPETING in *ROCK PLANTS FOR ALL PURPOSES.*

CARPINUS.—For the best species see *TREES.*

CARPOCAPSA.—See CODLIN MOTH in *INSECT PESTS.*

CARPOCERAS.—Now included in the genus *THLASPI.*

CARRION-FLOWER (*Smilax glauca*). See *SMILAX.*

CARROT (*Daucus Carota.* Nat. Ord. Umbelliferæ).—This, in addition to being one of the most useful, is also one of the easiest vegetables to grow, requiring nothing more than a deeply dug and fairly rich

soil to secure roots perfect in size, form, and colour.

Culture.—For very early crops sow in heated frames or mild hotbeds made up of leaves and fresh stable manure early in February. Thin sowing should be observed, and ventilation given on all suitable occasions. The very short sorts, termed Shorthorn, are suitable for the most shallow soils; for soils of a fairly deep nature the stump-rooted varieties growing about 4–8 ins. long are the most suitable, but where a good deep and rich loamy soil exists, specimens 2 ft. long may be had without any special preparation of the bed.

The first outdoor sowing may be made in a warm border any time after January, always selecting one of the small growing varieties. Cover the seed lightly with very fine soil to which a little wood ashes has been added, laying a few bushy sticks over the bed to keep it warm and induce a more rapid germination. After the seedlings are well through the soil remove the sticks, but should very cold winds or sharp frosts follow give a light scattering of hay or straw.

Where the soil is in a highly fertile state and of good depth, the Intermediate or Giant type should always have preference. In preparing the ground for these, fresh animal manure must be avoided, but where the soil is of an exceptionally hungry nature, and no manure applied for the previous crop, a good dressing of old hotbed manure, leaf-soil, or well-decayed vegetable matter will be an advantage. A light sprinkling of old soot, bonemeal, or one of the better known advertised manures, just previous to raking the surface level preparatory to sowing, is also allowable where the soil is poor.

Never attempt seed sowing when the soil is in a pasty condition; where this is so, draw the drills early in the morning of what promises to be a fine day, and sow the seed after the drills have been exposed to sun and air sufficiently long to make the soil friable and easily raked down. Cover the seed with half an inch of soil, and when the seedlings are well through the ground, thin out to at least 1 inch apart, further thinnings being made before the plants get crowded. For all ordinary purposes good carrots will follow if at the time of final thinning out the plants stand 8–9 ins. apart each way, more being allowed if extra large roots are expected. Keep the bed free from weeds, and during showery weather give repeated light applications of very old soot; this will serve a twofold purpose, keeping the foliage free from greenfly, and at the same time stimulating the growth. Lift the crop in November and store between layers of dry soil, or in pits in the open air.

For all varieties in the Shorthorn section 4 ins. between the drills will be ample. The stump-rooted require almost double this distance; while others of the Intermediate type need about 10–14 ins. between the rows.

Varieties:—*For Frames.*—Champion Horn, French Forcing, Little Gem.

For Early Borders.—Early Gem, Early Nantes, Guerande, Summer Favourite.

For Deep Soils.—Altrincham, New Red Intermediate, Prizewinner, Red Elephant, Red Surrey, St Valery.

For Shallow Soils.—Defiance, Matchless, and Sutton's Favourite. —F. R. C.

See also *ORNAMENTAL VEGETABLES*, and for METHOD OF BOTTLING see *VEGETABLE BOTTLING*

CARROT (*Daucus Carota*).—See *DAUCUS*.

CARROT FLY.—See *INSECT PESTS*.

CARTHAMUS (Distaff Thistle. Nat. Ord. Compositæ).—This is an unimportant genus of hardy annuals all of which are of exceedingly easy culture. The species most often grown is *C. tinctorius*, the well-known Safflower.

CARUM (Caraway. Nat. Ord. Umbelliferæ).—This is an unimportant genus of hardy biennials or perennials of very easy culture. *C. Bulbocastanum* is the well-known Pig Nut; *C. Carvi* is the common Caraway described in our article on *Medicinal Herbs*; while *C. Petroselinum* is the well-known herb used for garnishing and flavouring, namely, Parsley, the culture of which is described in its own article.

See also under Caraway in *Medicinal Herbs*.

CARYA.—For the best species see *Trees*.

CARYOPTERIS (Nat. Ord. Verbenaceæ).—This herbaceous perennial of doubtful hardiness is not largely grown. It will succeed in ordinary loam, though plenty of light humus is desirable. Planting may be done in the autumn or spring, though the last is the best time. Some winter protection is desirable. Propagation may be effected by cuttings of young growth, by division of the roots in autumn or spring, and also by seeds.

What to Grow.—Only three sorts are worth growing, namely, the following:—

Caryopteris mastacanthus.—This blue-flowered sort is useful for producing flowers in September. Height varies from 2 ft. to 5 ft.

C. mongolica.—This, a nondescript purple, violet, or doubtful blue, autumn blooming sort, averages about 3 ft. in height.

C. Wallichiana.—A red autumn blooming sort, averaging about 4 ft. in height.

CASCARA SAGRADA (*Rhamnus purshiana*).—See *Medicinal Herbs*.

CASHMERE SAGE (*Salvia hians*).—See *Salvia*.

CASSANDRA.—For the best species see *Shrubs*.

CASSENA (*Ilex Cassine*).—See *Holly*.

CASSINIA.—For the best species see *Shrubs*.

CASTALIA.—Now included in the genus Nymphaea.

CASTANEA.—For the best species see *Trees*.

CASTANOPSIS.—For the best species see *Trees*.

CASTOR OIL PLANT.—See *Ricinus*.

CAT MANURE.

This, as is well known, is a smelly solid rich in phosphates, as also is *Dog Manure*, upon which a separate note appears. Very little of it is available unless the garden is attached to a cats' home, so that it is hardly worth troubling about. If supplies are available, these may be mixed with farmyard or horse manure and dug in in the usual way in the winter.—E.

CAT TEASERS.—See *Cats in the Garden*.

CAT THYME (*Teucrium Marum*).—See *Teucrium*.

CAT WHIN (*Ulex europaeus nanus*). See *Shrubs*.

CAT'S-EAR.—See *Antennaria*.

CAT'S EAR.—See *Hypochoeris*.

CAT'S-TAIL GRASS.—See *Phleum*.

CAT'S VALERIAN (*Valeriana officinalis*).—See *Valeriana*.

CATALPA.—For best species see *Trees*.

CATANANCHE (Nat. Ord. Compositæ).—Two species of this are well worth growing. *C. caerulea*, the Blue Cupidone, is a blue-flowered hardy biennial blooming from July to August, and growing about 3 ft. high. A garden form *bicolor* (blue and white) is sometimes offered.

C. lutea is a yellow-flowered hardy annual blooming about the same time, and growing 9–12 ins. high. No special culture is needed by either; they may be propagated by division of the roots and by seeds in the usual way.

CATCH CROPS.

"What are catch crops?" uninitiated gardeners will ask. Very briefly, they are crops which are stolen from the land in a short space of time, either during the growth of another crop, or in the few remaining weeks of the season after that crop has been taken off the ground. All first-class gardeners use catch crops greatly, and thus get much more food from their land than they otherwise would do. Amateurs, however, and allotment holders have not yet realised the great value of catch crops, hence our reason for including this article.

Take, for instance, crops of peas sown in the garden. The best authorities advise a wide area being left between each row, some say not less than 4 ft., and others not less than 6 ft. Now it follows that if this course be adopted a great deal of land has to be allocated for the successful culture of the one crop of peas, and the return of food from the land is hardly great enough to do more than just about cover the cost of production. Market gardeners, of course, could not afford anything so extravagant as this. They have to make things pay, and every gardener ought to try to make things pay more than he does.

Reverting again to our rows of peas, if we leave 6 ft. of ground between each row, rather than waste this ground there are plenty of catch crops which may be sown and which will give a yield of food long before the peas are big enough to interfere with them. The two typical catch crops are early six weeks' turnips and spinach, and one gardener confessed to the writer the other day, that he made more money from his crops of spinach between his rows of peas than he did from the peas themselves.

Then take the case of root crops, such as parsnips, beetroot, salsafy, maincrop carrots, and so on, all of which occupy the ground for a very long period. If we consult the authorities they would say that these crops should have at least 15 ins. between each row. Quite so. But when we have only a limited area to grow vegetables upon such a distance as this between the rows means that we get very little return. If, however, we sow catch crops between each row, down go our costs, and up goes our production. It is possible to get two or three catch crops from one area by repeated sowing or planting during one long, single season alone.

One more example of the immense value of catch crops must be taken before we proceed to give a list. A plot-holder residing some eight miles from the present writer's house decided he would take up this problem of growing four times as much food as he had done previously, and this was how he managed it. Celery and leeks both took up large areas of his garden, areas which he said until lately had been difficult to afford on account of the great cost of production. Then it occurred to him to sow radishes between his rows of leeks and celery, and to sow lettuce mixed with the radish seed, and between every celery or leek plant he set a plant of endive. He had thus four crops on his celery patch and four on his leek patch where only one had grown before. Naturally the first

crops to mature were the radishes, which were ready very soon after sowing. Then came the lettuce, and after that the endive, which, of course, had to be tied up. None of these crops interfered with the celery or leeks in the slightest degree, since the trench system was not adopted, and a second crop of both lettuces and radishes was got from the same piece.

The Chief Crops.—The chief catch crops which are useful to the gardener are early carrots, corn salad, endive, globe beet, lettuce, radish, spinach, and six weeks' turnips. The culture of these is fully dealt with under their respective headings, but the following hints may be useful :—

Sow the first catch crops when you sow the main crops, for the earlier seed is in the ground the better.

Pay as much attention to your catch crops as you do to your main crops, and clear them off the ground as early as possible.

As soon as one catch crop is finished, sow or plant another, and have beds of transplantable stuff coming on in the reserve garden for the purpose.

Keep your catch crops thoroughly well soaked with water, and give them frequent doses of weak liquid manure.

And lastly, keep all catch crops as free from weeds and as thoroughly well hoed as it is possible to do in the restricted area in which they are grown.—E.

See also *KINDS OF CROPS*.

CATCHFLY.—A name applied to the genus *SILENE*, which see. See also *LYCHNIS*.

CATERPILLARS.

A number of different kinds of caterpillars are treated by another contributor under *INSECT PESTS*. But a few words may be said about one of the worst caterpillars, namely, the Cabbage Caterpillar, of the White Cabbage Butterfly. This caterpillar has an enormous appetite, and it greedily eats up any plants of the Cabbage family which it may come into contact with, as well as other plants. There was a regular plague of these caterpillars in some districts in 1917, hence the present writer offered a few small prizes to children who sent him the largest number collected between August 20th and October 31st. The winner of the first prize sent 3000, and several other competitors sent 2000 caterpillars or more.

Undoubtedly hand-picking is the best way of dealing with these caterpillars, but steps should be taken to kill all cabbage butterflies as early in the season as possible, to prevent the number being great. There is said to be a way of introducing a disease, but this is in an experimental stage as yet, and we shall probably hear more about it later.

A mixture of soft soap, salt, and warm water has been recommended as a spray for the cabbages infested with these caterpillars, but it is not so good as hand-picking.—E.

CATHCARTIA (Nat. Ord. Papaveraceæ).—An interesting plant with hairy leaves. It is a biennial and must be raised every other year from seed sown in gentle heat in March. It thrives in the shady part of the rock garden. Only one species need be troubled with :—

C. villosa.—Leaves in rosettes. Flowers yellow (Poppy-like), on leafy stems. Soil rich peat and loam. Flowering Period, June to July. Height, 1 ft.

CATHISSA.—Now included in the genus ORNITHOGALUM.

CATMINT (*Nepeta.* Nat. Ord. Labiatæ).—No gardening diction-

ary would be complete without a brief reference to this plant which brings back by its appearance and its aromatic scent thoughts of happy childhood days, spent rambling among flowers in old world gardens. Catmint culture is on the decline, and more is the pity, for the silvery-grey foliage of the plants makes a thick and beautiful carpet along the front of the perennial borders, and knolls in the rock garden covered with Catmint are remarkably pleasing. The least desirable species of all, *N. Glechoma*, is with other species used in herbal medicine.

Culture of Catmint is a remarkably easy matter. Plants should preferably be purchased in the autumn and then set in good rich ground to flower, and grow with great freedom the following season. Propagation is an easy matter; the best means of effecting this is by division of the roots in March, but cuttings of young growth slipped off after the plants have flowered will also give satisfactory plants. We recommend the following, all of which are hardy perennials :—

Nepeta Cataria.—This is so similar to *N. Mussini* that it is often mistaken for it.

N. Glechoma.—This, the GROUND IVY, and its variety *variegata*, the VARIEGATED GROUND IVY, are both undesirable and weedy plants which should not be grown save for medicinal purposes, and even then strictly limited.

N. longiflora.—This nurserymen's sort, given specific rank at Kew, is practically indistinguishable from *N. Mussini*, and may be considered synonymous with it.

N. macrantha.—This bears pretty blue flowers in July and August, on plants 12–18 ins. high.

N. Mussini.—This is the species we are fondest of, with its scented silvery-grey carpeting foliage and violet or blue-violet flowers. It blooms all the summer, and averages 9–12 ins. high.

N. Nepetella.—This is the pretty plant popularly known as SMALL CATMINT, bearing red flowers from June onwards, and growing 9–12 ins. high.

See also *POTHERBS*.

CATS IN THE GARDEN.

Gardeners have the idea that Cats are very undesirable visitors of the garden; thus in some works by us we find articles on "How to get rid of Cats," and illustrations of various "Cat Teasers."

But we are not willing to admit that cats are so undesirable as they are made out to be. Some cats are very destructive, but so are some dogs, and dogs are frequently more destructive than cats. Stray cats and dogs alike are unwelcome, on account of their undesirable habit of "foraging," but the domesticated pussy is quite capable of walking up and down the grass path between the herbaceous borders admiring the flowers.

Have you never seen a pussy, reader, enjoying an evening stroll in the flower garden? It is an amusing sight. Quite slowly she walks down the path, her head in air, stopping with the manner of a connoisseur from time to time, to admire the various flowers. She is fond of gay flowers and pleasant smells quite as much as you are, reader, and she regularly enjoys herself walking about studying flowers so demurely. But why should this harmless creature be regarded as an enemy of the gardener? She does no harm. She merely views the gardener's handiwork, and perhaps laughs at him a little sometimes, saying to herself: "If this were my garden I could make it much nicer. I should have some big beds of Catmint to roll

in, and some large cushions of Rock-foil to sit upon."

Perhaps the gardener does not like his work being criticised by cats. But why should he object, I wonder? If he were to build a bridge instead of making a garden, it would be open for anyone from the veriest tramp to the greatest nobleman to criticise it. After all, cats are not great critics, so he must not much mind; they put their backs up when they are annoyed at the gardener putting two clashing colours together, and they purr when they reach a large group of plants which specially pleases them; but that is about as far as they go.

We are glad that Miss Jekyll (one of our valued contributors) bears out our appreciation of the domesticated pussy in one of her books. We consider that a pussy who is appreciative of flowers should be made a friend of by the gardener, and then she will probably repay him in her "working hours"—for of course even domesticated cats work very hard—by guarding his beds of small seeds from troublesome sparrows.

The above remarks apply to the domesticated pussy. The busybody tom-cat, who is as uneducated as he is active, is no real friend of the gardener. He tears across the garden in false pursuit of rats and mice, scratches up borders trying to find their nests,—though they seldom if ever make nests in so public a place,—jumps up trees, and springs on to choice shrubs in attempting to catch birds, and, in a word, does untold damage in a very short time. Such cats should be kept out of the garden as completely as possible; they are very useful for the stable-yard, but they must be regarded as being unfit to meet or converse with the ladylike domesticated pussy.—E.

CATTLEYA.—See *ORCHIDS.*

CATTLEYA FLY.—See *INSECT PESTS.*

CAULIFLOWER (*Brassica oleracea botrytis cauliflora.* Nat. Ord. Cruciferæ).—These are among the most highly prized of all summer and autumn vegetables, and for this reason they well repay the extra attention necessary if milk-white compact heads of good size and shape are to follow.

Many valuable additions have lately been made to the list of sterling varieties, and for this reason it is advisable that selection be not limited to one sort or one sowing. By means of successive sowings, cauliflowers may be had during the whole of the period when the more hardy Broccoli are not available. The first fully developed head should be ready before the end of May, the last, only after severe frost has killed the plants, at quite the end of the year.

For Early Work.—To supply good heads by 20th May, a sowing should be made in a heated greenhouse or on a mild hotbed early in February. Sow the seed in well-drained pans filled with rich soil, to which sufficient coarse sand has been added to ensure porosity. This is of utmost importance, and where not observed, disastrous results may follow a short time after the seedlings appear above the soil. Sow the seed very thinly to allow for sturdy growth, until each seedling is sufficiently strong to bear transferring to other pans or small pots with the least possible check to growth. Harden off by placing into cooler quarters, and plant out in the sunny borders, or under hand-lights early in April.

Sowing Out of Doors.—It is rarely safe to do this until the first week in April, and then a sheltered corner exposed to full sunshine should be selected. The seed-bed should be similar to that described in the

article on *Broccoli* (which see). The first fortnight in May will be quite soon enough to make the main sowing; plants from seed sown at this date usually giving perfect heads until Christmas, or later, if a reliable strain of seed is purchased.

Throughout all stages of growth a rich soil should be provided, and until the plants are well established in permanent quarters, they should never be allowed to become dry. On the other hand, a constantly saturated soil should be studiously avoided.

Planting Out.—As early in the spring as possible, the permanent bed should be liberally manured, burying the manure at least 12 ins., thus enabling the plant to get the full benefit from the moisture this contains, just when bright sun, and possible drought, renders moisture of paramount importance to the hungry young roots. The distance between the early varieties need not exceed 20 ins. each way. Those planted later should be allowed a trifle more room, many of these developing heads equal in size to what are termed the Giant class. The last batch will repay a distance of 3 ft. between the rows and 2½ ft. between the plants.

Manure water, or an application of artificials, may be given as soon as the roots get well hold of the soil and are growing freely, but where this can only be had in very limited quantities it will be better to defer feeding until the curds are just forming, a little extra stimulant at this stage quickening the development, also adding to the size of the heads.

Early crops may also be had by sowing in the open early in August, potting and giving the plants the protection of a garden frame during the winter months, planting out in sunny borders early in April.

Varieties:—*For Earliest Crop.*—Earliest of All, Early Paris, Eight Weeks, Snowball.

Second Early.—All the Year Round, Early Erfurt, Early Giant, Magnum Bonum, Matchless, Standwell, Walcheren.

Late Autumn.—Autumn Giant, Autumn Mammoth, Eclipse, Emperor.—F. R. C.

CELERIAC (*Apium graveolens rapaceum.* Nat. Ord. Umbelliferæ).—Unlike celery, this is grown for its large fleshy roots, which when cooked have a distinct celery flavour. It is sure to give satisfac-

tion to those who appreciate celery as a boiled vegetable.

Culture.—Sow and treat as advised in article on *Celery*, excepting when large enough for the open, these may be planted on the level instead of in trenches. Always provide a good rich soil, allowing not less than a foot between the plants. Water very freely in hot weather, and early in November lift the roots and store under eaves in dry soil or ashes.—F. R. C.

[Celeriac should be more often grown than it is.—Editor.]

See also *Apium*.

CELERY (*Apium graveolens*. Nat. Ord. Umbelliferæ). — First-class cultivation of this means not only increased size and weight of the crop but vastly improved table quality. On the other hand, examples grown upon the starvation system, not only lack size, but the quality is often such as to render it useless for almost any purpose.

Preparation of Ground.—Celery is fonder of moisture than almost any other crop. Keeping this fact in mind, where the soil is of a very light or hungry nature, plenty of good rich manure, well-decayed leaves, garden refuse, or lawn mowings from the previous summer should be reserved for adding to the site where this crop is to be grown.

In saying this it is not meant to imply that an extravagant dressing of manure for Celery is absolutely essential, neither is it necessary to dig extra deep trenches for the crop. What is needed is the absolute certainty that plenty of moisture shall reach the roots during the period of active growth, hence the necessity of a trench of some kind. If planted on the level, it would be almost impossible to keep the roots moist in a dry season, but if the trench is made about 12–15 ins. deep it will allow ample space for a good layer of manure, also a covering of not less than 6 ins. of fine soil, and still leave a good margin to form a channel for the water to be poured into. The width of the trenches must be governed by the number of rows it is intended to plant in them. Where but a single row is desired, 10–12 ins. will be ample. For a double row not less than 16 ins. should be allowed. We ourselves having grown three rows of excellent celery in a trench barely 20 ins. wide, would point out to the small grower, that where the rows are situated some considerable distance from the water supply, the double or treble row should always have preference, since they require very little more water than that usually given to a single row. The treble row should also be favoured by those who desire a good supply over a long period; this not only economises space and manure, but it will be found the necessary cultural details may be more quickly, equally, and efficiently performed when these are all together, than is possible when each row is grown in a separate trench.

Sowing.—Where well-grown and perfectly blanched celery is desired early in September, a pinch of seed should be sown in a moderately heated greenhouse during the first fortnight in February; for this sowing one of the white varieties is more likely to give satisfaction than the pink or red. The seed should be sown in a well-drained pan filled to within half an inch of the brim with a compost containing equal parts finely sifted loam, leaf-soil, and coarse silver sand. The seed needs only a very slight covering of fine sand or soil, after which

it should be pressed firm and watered through a fine-rosed can, covering the pan with a sheet of glass or brown paper. If the latter is used, be careful to remove it directly the seed shows signs of germinating, but where glass is used, its retention over the pan until the seedlings touch the top will be an advantage. Seedlings need very careful watering, and none but tepid water should be used, always erring on the dry side.

Pricking Off, etc. — The plants are ready for pricking off as soon as two true leaves have been formed. Shallow boxes filled with soil, similar to that the seed was sown in, should be used, putting a layer of well-decayed manure or leaves at the bottom, and after pressing moderately firm, cover the surface with a good layer of sand, or ashes from the garden bonfire. Allow about 2 ins. between the plants, and after a gentle sprinkling overhead, stand the boxes in a light position and shade from bright sun until the condition of the plants shows some roots have been made. After that expose to all possible sunshine and gradually harden off, planting in their permanent quarters early in May.

Maincrop Celery.—The middle of March will be quite early enough to sow seed for the main or winter crop, when the details just given should be carefully followed, until the pricking-off stage is reached. Then, instead of the shallow boxes recommended, it will be an advantage to make up a bed of rich soil over a layer of old hotbed manure in an ordinary garden frame. [We make our soil-bed on a mild hotbed.—EDITOR.] If the seedlings are transferred direct from the seed-pan to this, each being set 2½ ins. apart, and the bed kept well watered and carefully ventilated during bright days, good plants 6 ins. high or more should be ready for planting out about the middle of June; and thanks to the rich soil and room allowed, the plants may each be transferred to their trenches without the slightest check. Before putting them in their final quarters the soil should be trodden very firm, planting always being done with a trowel. Allow about 8–12 ins. between the plants in the row, and 8 ins. or more between the rows.

As soon as the plants get well established in permanent quarters, dryness at the root must be guarded against, as this frequently causes them to run to seed. As growth proceeds many of the outer leaves of each plant will show a tendency to fall, and thus become mixed with others in the next plant. If left long in this state, even if very carefully handled, considerable damage invariably results. A plan far better than taking this risk is to loop up these outside leaves as growth proceeds, never allowing the tie to become so tight as to damage them or impede growth.

Growers who are unable to give the plants liquid manure, will find by tying the leaves together as suggested, dry or artificial manure may be more easily distributed, and afterwards well stirred into the soil, than is possible where tying up is not attempted. Commence giving stimulants as soon as the plants are about 1 ft. high. Weak and often is a golden rule to observe, always keeping whatever is used from direct contact with the leaves, or harm may follow.

One of the very finest liquid manures for celery on a light soil is that from cowsheds, to which a little sulphate of ammonia has been added. In making this, 1 bushel of fresh cow manure is ample for a

40-gallon cask of water. Half an ounce of sulphate of ammonia should be added to each gallon at the time of using. Other good stimulants are soot water and fish guano, using 1 peck of the first to 20 gallons of water, or one handful of the latter to six plants, well stirring it into the soil.

Blanching.—A point to observe when earthing up is always to keep the leaves close together in such a way as to prevent the fine soil getting into the heart of the plant. Thin cardboard or stout brown paper is often preferred to soil for blanching purposes, by busy growers, more particularly those who aim at very early supplies. The paper should not be put round until a good length of stem has been made, successive bands being added as growth proceeds. If preferred the plants may be left unpapered until growth is complete, or six weeks before the celery is required for use. When placing these paper collars around the plants always allow for a little expansion, but put them on in such a way as to ensure absolute darkness to the stem beneath. Plants round which paper has been tied should have additional protection given them before severe frost sets in, or much damage may result when least expected. Even rows properly earthed up with soil or ashes should be protected by means of hay or other light material during exceptionally severe weather.

Insect Pests include Celery Leaf Miner, and Aphis (which are dealt with in the article on *Insect Pests*).

Varieties are very numerous and distinct, the best of these being the selection now given: Aldenham Pink, Champion Early, Clayworth Prize Pink, Early Market White, Manchester Red, Sandringham White, Standard Bearer, Sulham Prize, Superb Pink, Sutton's A1, Sutton's Solid White, Wright's Giant Red.—F. R. C.

CELLAR GARDENING.

During the winter the possibilities of a cellar for certain forms of plant culture should not be overlooked. In these underground apartments the temperature often is relatively high, and is usually maintained well above freezing-point even during severe weather. The deficiency of light in a cellar hampers ordinary growth on the part of vegetation, but the darkness is no hindrance to the development of crops that are forced in blanched conditions. Seakale and Chicory do particularly well in such situations. The roots are lifted from the ground and placed in pots or boxes with a little soil. Water should be given somewhat sparingly, as where there is excessive damp, fungoid growths, such as mould, are always likely to appear in a cellar. This plan, in the case of the above vegetables, may be carried out from the fall onwards through the winter.

Another useful plant for the cellar is Dandelion. Strong roots should be lifted from the fields and wayside and potted up, very little soil being required. These plants send up a fine blanched growth that is excellent for salad purposes. Rhubarb is also an ideal crop for the cellar gardener. The clumps are lifted from the ground towards the late fall. If they are exposed to a few nights' frost they will force all the more readily. Finally, the roots are packed closely to-

gether on the floor of the cellar, a small amount of rather dry soil being shaken in between them. Moisture is needed, of course, but, until the plants are growing actively, it is safer to keep them on the dry side. Excellent stalks are quickly produced, and these may be secured at a very early date.

Cellars are naturally ideal positions for the growing of Mushrooms, though some objection may be raised by the sanitary officials to the presence of manure in rooms under a dwelling-house. As a matter of fact, the material does not give out much odour if it is stacked out of doors for ten days, and repeatedly turned, before being introduced into the cellar.

Almost the only difficulty which confronts the gardener in the cellar is excessive damp, which leads, as we have said, to the appearance of mould on an extensive scale. Water should be sparingly given to the plants, and this is more quickly absorbed if the chill is slightly taken off. Another useful step is the daily ventilation of the cellar as far as possible. Often by leaving the door and window (if there should be one) open for a short while, the heavy stagnant air, so favourable to fungoid activity, is very much relieved.—S. L. B.

CELMISIA (Nat. Ord. Compositæ). This is a genus of evergreen tufted greenhouse and hardy plants with hard leathery leaves and large Daisy-like flowers. With the greenhouse sorts we need not trouble here; the hardy kinds will, however, thrive in half-shady or sunny positions in the rock garden. They are propagated by seeds sown in gentle heat in March. The best are:—

Celmisia holosericea.—This is an evergreen sub-shrubby plant, bearing hard, leathery leaves in rosettes and making large patches. Flowers white, borne singly on stems and very large. Site, half-shade. Soil peat, loam, and rubble. Flowering Period, June to July. Height, 1 ft.

C. Mackani.—This bears leaves in tufts and has no stems. Flowers white, and large. Site, half-shade. Soil peat, loam, and rubble. Flowering Period, June to July. Height, 1 ft.

C. spectabilis argentea.—This is one of the best sorts and bears its leaves, which are leathery and silvery, in tufts close to the ground. Flowers white and numerous, borne singly on stems. Site sunny. Soil rocky. Flowering Period, June to July. Height, 1 ft.

CELOSIA (Prince of Wales Feathers. Nat. Ord. Amarantaceæ).—This is a most useful plant for greenhouse and conservatory decoration, and very effective in pots, making a grand display during the autumn. Seed should be sown in spring in a little warmth, in light rich loam, leaf-mould, and sand, and the pots should be well drained. Temperature required, 45–50° F.

Greenhouse Species:—*Celosia aurea.*—Yellow plumes. Flowers in August. Height, 1–1½ ft.

C. coccinea.—Crimson and scarlet plumes. Flowers in August. Height, 1–1½ ft.

C. cristata.—This is the Cockscomb, bearing deep crimson flowers in July. Height, 1–1½ ft. See article on *Cockscomb.*

C. pyramidalis.—Brilliant crimson plumes. Flowers in August. Height, 1–1½ ft.

C. Thompsoni magnifica.—Rich-coloured plumes. Flowers in August. Height, 1–1½ ft.

CEMETERY GARDENING.

A word must be said on this matter here, as this form of gardening happily is coming more to the fore. Old grim churchyards devoid of any beauty still exist in hundreds, it is true, but the newer ones and the town and city cemeteries are fortunately planned out very differently.

Briefly, the schemes are as follows. First, to arrange the churchyard or cemetery in such a way that on both sides of the central paths or drive up which every funeral party has to come, are flower-beds filled with bright plants; and secondly, to have on the margins of such churchyards or cemeteries hardy flower borders or banks of flowering shrubs. The use of flowering shrubs is specially desirable, since their loveliness appeals to all, and an effort should be made to plant shrubs not only which bloom in the spring, but also in the summer and autumn. (See article *FLOWERING SHRUBS.*) A very large number of bedding plants and hardy perennials are available for use in the beds and borders.

One uncommon idea which the writer saw recently seems worth mentioning here. The cemetery was divided up into several sections, and on both sides of each drive poles or pillars were driven in. Up these grew roses, and drooped down again, giving the drives a peculiarly lovely though solemn appearance. *American Pillar, Crimson Rambler, Dorothy Perkins, Hiawatha,* and *Minnehaha* were all there, and many others too. The Superintendent when questioned said they had roses blooming there from May to November.

Climbing plants might be generously used for clothing the walls of Cemetery Chapels, Churches, and Mausoleums to beautify them. Readers interested will find a host of these plants described in our article on *CLIMBING AND TRAILING PLANTS.*

Money spent on beautifying cemeteries and churchyards by planting as above indicated is never wasted, as although it can do no good to the departed, it will often inspire those who remain to live nobler and purer lives.—E.

CEMIOSTOMA.—See PEAR LEAF BLISTER MOTH in *INSECT PESTS.*

CENCHRUS (BURR GRASS. Nat. Ord. Gramineæ).—This is a curious genus of hardy grasses suitable for the wild garden. The best species is *C. tribuloides,* the HEDGEHOG GRASS, which grows about 1 ft. high.

CENTAUREA (CENTAURY, KNAPWEED, etc. Nat. Ord. Compositæ).—This genus is so extensive that twenty columns of the *Index Kewensis* are filled with its species and their synonyms. It includes many useful garden plants; some, however, are of botanical interest only and little better than weeds.

Annual Species.—In this very large family there are two groups of well-known annual garden plants, the CORNFLOWERS and the SWEET SULTANS, and both are very largely grown for the supply of cut flowers for market. The Cornflowers are very easily raised either from an autumn sowing or a sowing made in March or April. Autumn sown seedlings lightly thinned out, bloom early in the following summer; for groups in the flower border the plants should be thinned to 1 ft. apart. Cornflowers do not take kindly to transplanting.

Sweet Sultans are so beautiful that they repay any extra trouble taken to grow them well. In light soil, especially one containing plenty of lime or chalk, a sowing in autumn will prove successful, and should be made where the plants are to flower. Seedlings raised early in the year in a frame, transferred singly to small pots while quite small, and planted out in May give excellent results. The soil must be good, and as the plants develop it is a good plan to place a few twigs among them to prevent damage from wind.

For varieties of these two popular annuals, see the separate articles dealing with them, namely, *Cornflower* and *Sweet Sultan*. The half-hardy sorts, such as *C. Cineraria* (Syn. *C. candidissima*), are comparatively unimportant and are omitted; they were once much used for summer bedding.

Biennial Border Species.—These are useful border plants and may be raised from seeds sown in the open ground during May, or in pots placed in a cold frame, planting out the seedlings when they have made a few rough leaves. We recommend the following :—

Centaurea arachnoidea.—A useful yellow July blooming sort, growing about 3 ft. in height.

C. Fenzlii.—This is an erect branching plant bearing large canary yellow heads surmounting its long leafless stems in July and August. Height about 4 ft.

C. iberica.—This is a purple July blooming sort about 1½ ft. high.

C. salmantica.—A purple sort blooming in June and July. It grows about 3 ft. high.

Perennial Border Species.—There are several hundred species which are more or less suitable for hardy flower borders, and all thrive in ordinary garden soil in an open, sunny position. The taller and more weedy sorts may be planted in shrubbery borders or in the wild garden. None are suitable for the rock garden save for the rougher parts, as they are essentially border plants. Propagation is not difficult; it may be effected by seeds sown in the usual way for hardy perennials in the spring or summer; or again, division of the roots is a satisfactory way of increasing one's stock. The less weedy kinds are eminently suitable for cutting, and all may be successfully planted from October to the end of March. The taller sorts need efficient staking, or they fall about and lose much of their beauty. We recommend the following :—

Centaurea alba.—This is a white July flowering sort growing about 2 ft. high. Its variety *deusta* (Syn. *C. deusta*) bears red flowers and grows twice as tall.

C. amara.—This is a purple sort flowering in June and July, and growing about 2 ft. high.

C. atropurpurea.—This is a much darker coloured sort than the above. It blooms about the same time, and averages a yard in height.

C. babylonica.—This is a useful very tall yellow July blooming sort suitable for sunny shrub borders. It grows about 6 ft. in height.

C. Barrelieri.—This purple July blooming sort grows about 1½ ft. high.

C. dealbata (Mealy Centaury).—This is a purple July flowering sort growing about 2 ft. high.

C. deusta.—Syn. *C. alba deusta*, which see.

C. eriophora.—This bears yellow blooms from July onwards, and grows 3 ft. high.

C. glastifolia.—This yellow sort blooms in July, and grows 4 ft. high.

C. Jacea (Brown Knapweed).—This purple sort flowering from June to September is not much grown. Its height averages half a yard.

C. macrocephala (GREAT KNAPWEED).—This is a yellow sort flowering in July, and growing a yard in height.

C. montana.—This is an attractive blue July flowering species growing about 2 ft. high. Its flowers are useful for cutting. Two good varieties of it are:—*alba* (white) and *lugdunensis* (blue).

C. nigra (BLACK KNAPWEED).—This is a dark purple species flowering freely throughout the summer, and growing 2 ft. high.

C. Rhaponticum (SWISS KNAPWEED).—A purple summer flowering sort of no great consequence. Height, 2½ ft.

C. ruthenica.—A pale yellow August flowering sort about a yard high.

C. Scabiosa (GREATER KNAPWEED).—This sort bears purplish flowers from June well into the autumn, and grows about 1½ ft. high.

C. uniflora.—This is a purple July flowering sort growing about 1 ft. high.—C. H. C., J. F., & E.

CEPHALOSTACHYUM.—See *BAMBOOS*.

CEPHALOTAXUS.—For the best species see *TREES*.

CERASTIUM (MOUSE-EAR CHICKWEED, SNOW IN SUMMER. Nat. Ord. Caryophyllaceæ).—A genus of dwarf carpeting plants with silvery foliage, valuable for covering large spaces in the rock garden, rock border, or wall garden. To propagate, divide in autumn or spring; or seeds may be sown in a little heat in March.

Rock Garden Species.—Those usually grown are briefly described below:—

Cerastium alpinum.—A woolly-leaved silvery plant. Flowers white. Site sunny ledge. Soil gritty sandy loam. Flowering Period, June to July. Height, 3 ins.

C. Biebersteinii.—A very free-growing, white-leaved species soon covering a large area. Flowers white. Site sunny. Soil sandy loam. Flowering Period, May to July. Height, 6 ins.

C. tomentosum.—Leaves small, silvery, evergreen. Flowers white. Site sunny ledge. Soil gritty loam. Flowering Period, June. Height, 3 ins.

CERATOCEPHALUS.—Now included in the genus *RANUNCULUS*.

CERATOCHLOA.—Now included in the genus *BROMUS*.

CERATOSTIGMA (LEADWORT. Nat. Ord. Plumbaginaceæ).—A late-flowering plant, useful for the rock garden. It thrives on a rocky bank in ordinary soil, and is propagated by dividing the roots in autumn.

C. plumbaginoides (Syn. *Plumbago Larpentae*).—A bushy species, the leaves of which turn bronze colour in autumn. Flowers cobalt blue. Flowering Period, September to October. Height, 1 ft.

NEW SPECIES.

Ceratostigma Willmottiana.—This bears light blue flowers throughout the summer, and grows about 6 ft. high.

CERCIS.—For best species see *TREES*.

CEREFOLIUM.—Now included in the genus *ANTHRISCUS.*

CEREUS.—See *CACTI.*

CERINTHE (HONEYWORT. Nat. Ord. Boraginaceæ).—This is a small genus of attractive hardy annual plants growing with remarkable freedom in ordinary garden loam. The best species are *C. aspera* and *C. major* (Syn. *C. gymnandra*). The first bears purple and yellow blooms, while the second is pure yellow. Both bloom in July, and average 2–3 ft. in height.

CEROPTERIS.—Now included in the genus GYMNOGRAMME, for which see *FERNS AND FERN GARDENING.*

CETERACH.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

CHAFERS.—See *INSECT PESTS.*

CHAIRS AND AWNINGS.—See *GARDEN FURNITURE.*

CHALCIDIDÆ.—See under CATTLEYA FLY in *INSECT PESTS.*

CHALK.

This is, chemically, carbonate of calcium ($CaCO_3$), but it is more often called carbonate of lime, which name is undesirable as well as incorrect, since lime is not in itself a metal, but an oxide of the metal calcium. Chalk is useful to the gardener in several ways. It is extremely useful as a mild antidote for acids on rich soils, and can be safely applied heavily without fear of loss of much valuable plant food, which would take place where quicklime or slaked lime were applied. Animal manure and chalk can be applied together, but lime and dung cannot, owing to chemical action; basic slag and chalk also can be applied together, but not basic slag and quicklime, owing to chemical action again; and finally, chalk can be mixed with ammonia compounds to neutralise the acid effect they have on soils, but quicklime would, if mixed with them, drive off all the ammonia. Chalk can further be used in reclaiming for neutralising the harmful vegetable acids in peat without injuring the rich humus it contains; if quicklime were used for the purpose much of the valuable humus would be destroyed.

Chalk is a very mild and safe material. It can be applied (if finely ground) at any time, and beneficial results have been obtained by hoeing chalk into the soil among flowers and vegetables a few days after they have had a somewhat heavy feed of nitrogenous or ammoniacal fertilisers. Chalk is the stand-by of the gardener who works upon a very sandy soil; on such, a dressing of quicklime or slaked lime would be fatal, and would effectually remove any little humus which the soil had been able to manage to retain. Chalk, especially if it is obtained in the form known as *Chalk-marl*, helps to bind such very open soils together, and makes them hold moisture and manure much better. In this case the chalk, when delivered, will be in lumps or irregular masses. These have to be spread out on the ground in the autumn or not later than 1st December, so that the frost can get at them and break them down. In the spring a few blows with the spade will soon finish the crushing. After that, the chalk can be dug in with manure. From 3–6 stones of chalk per sq. rod of ground can be safely used.—E.

CHAMOMILE.—See *ANTHEMIS* and *MEDICINAL HERBS*.

CHANTARELLE.—See EDIBLE FUNGI in *FUNGI*.

CHARACTER OF BEDS.—See *BEDS: SHAPE AND CHARACTER OF*.

CHARCOAL.

This finds varied use in the gardener's hands, but is not of any very great importance. It is an ingredient of potting soils for many plants, and a couple of pots full of charcoal dust per bushel of soil, or even more of the lump charcoal, can after crushing be used. Lump charcoal can be put instead of potsherds at the bottom of pots for drainage purposes, and it ensures the soil being kept sweet. It can also be put into vases for keeping the water of cut flowers fresh and sweet. One small lump in the bottom of each vase is usually quite sufficient for the purpose, and is said to be better even than permanganate of potash.

Out of doors, charcoal dust can be used in the preparation of seed-beds. It may be used either alone or mixed with wood ashes. It can be forked in freely round extra choice plants.

There is a form known as *animal charcoal*, but the gardener has no use for this. The remarks above apply only to wood charcoal.—E.

CHARIEIS.—See *CAPE ASTER*.

CHATHAM ISLAND FORGET-ME-NOT (*Myosotidium nobile*).—See *MYOSOTIDIUM*.

CHEDDAR PINK (*Dianthus caesius*).—See *DIANTHUS*.

CHEIMATOBIA.—See WINTER MOTHS in *INSECT PESTS*.

CHEIRANTHUS (Nat. Ord. Cruciferæ).—A very large number of species of this pretty little genus are described in the older gardening works, but modern research has proved them to be synonymous with species of other genera. According to the Kew Hand-list *Cheiranthus Chius* is now *Malcomia Chia*; *C. flexuosus* is *M. flexuosa*; *C. incana* is *Matthiola incana*; *C. littoreus* is *Malcomia littorea*; *C. maritimus* is *M. maritima*; and *C. sinuatus* is *Matthiola sinuata*. The species described below are hardy perennials suitable for rockwork or the warmest parts of the perennial border, and thrive in light sandy soil. They are best propagated by seeds sown in the spring or summer, or by autumn or spring division of the roots. In cold districts it is advisable to defer planting till March.

Cheiranthus Allionii.—This lovely sort bears deep orange flowers from May onwards, and averages 12 ins. high.

C. alpinus.—This is the popular ALPINE WALLFLOWER of the nurserymen, bearing pale yellow or sulphur-yellow flowers in May and June, and growing 6 ins. high.

C. Cheiri. See article on *WALLFLOWERS*.

C. Marshallii.—This bears glorious orange flowers throughout the early summer, and grows 1–2 ft. high.

C. Menziesii.—This is a useful sort bearing clear purple flowers from April onwards to June. It grows 6–8 ins. high.

CHELONE (Nat. Ord. Scrophulariaceæ).—This genus is coming to the front, but a great many of its species are now included in *PENTSTEMON*, to which reference should be made. Even the well-known *Chelone barbata* is now included in the Pentstemons. They may be used for the usual purposes in the herbaceous border, etc., though in very cold districts some winter protection is desirable.

Culture.—Chelones are not particular as to soil provided it is on the light side. Some well-decayed humus should be supplied if the best flowers are wanted. They do well in south borders, but may also be planted in the less overgrown and sunniest parts of the wild garden and in the rock garden. They may be increased by seeds sown in the usual way, by cuttings made in the way described under *PROPAGATION OF PLANTS*, and by division of the roots in the autumn or spring. Plant any time from early November onwards, or in cold localities delay planting till the spring.

What to Grow.—We recommend the following :—

Chelone barbata.—This is now named *Pentstemon barbatus*. See article on *PENTSTEMON*.

C. cheilanthifolia (Syns. *C. centranthifolia* and *Pentstemon centranthifolia*). See article on *PENTSTEMON*.

C. glabra.—A useful white August blooming sort averaging about 4 ft. in height. Its variety *obliqua*, by some considered as a separate species, is purple.

C. Lyoni.—This is a purple August flowering sort about 4 ft. high.

C. mexicana.—An attractive scarlet sort, blooming in the early summer (June). Height, 1 ft.

C. nemorosa.—A dwarf purple flowered sort, coming in during August, and averaging 12–15 ins. in height.

C. obliqua.—This is, as already mentioned, by some considered a separate species. It appears to be only a variety of *C. glabra*, to which it is very similar.

C. speciosa.—A reddish sort blooming in August and continuing at times into the early autumn. It averages about 4 ft. in height.

See also *PENTSTEMON*.

CHEMICALS FOR GARDENS.—See *GARDEN CHEMICALS*.

CHEMISTRY FOR GARDENERS.

Chemistry is the science that deals with the changes which matter undergoes. There are also physical changes which take place in connection with matter. The latter are, however, only changes in form, whilst the former are changes in composition.

Acids, Bases, and Salts.—Readers will find constant references to these elsewhere, so a few words explaining exactly what they are may be useful. An *acid* considered chemically contains hydrogen, but for our purposes we may say that it has the power of neutralising a base. A *base*, on the other hand, has properties opposite to those of an acid. If the two combine, a *salt* is formed. As an example of such changes spirits of salts (hydrochloric acid) may be taken. It has the characteristic properties of an acid, for it is sour to the taste, and it turns blue litmus paper red. If now caustic soda (a base which turns red litmus blue) be added, the properties of the latter disappear at a certain point, for the soda, which is a base, has combined with the acid to form common salt (sodium chloride).

Chemical changes such as the above are of great importance to gardeners, and an example of a change where undesirable compounds are removed from the soil by this means, is found in liming the land to neutralise the poisonous vegetable acids it may contain after over-manuring.

The chemist tells us there are two classes of matter—*organic* and *inorganic*. By the former is usually understood those substances which have been produced by living organisms (animal or vegetable), whilst inorganic matter has been produced without the aid of a living plant or animal. The distinction between organic and inorganic material is useful, and if by

organic is understood what we regard generally as animal or vegetable products, the term is not likely to be wrongly used. Strictly speaking, however, organic chemistry is the branch which deals with the compounds of the element carbon.

A great many of the changes which give rise to new compounds take place in solution, and water is the solvent that most commonly comes into consideration. Some elements or compounds do not dissolve in water nearly so easily as others; but nothing is really insoluble, although such materials as glass, metals, etc., only dissolve after they have been heated in water for lengthy periods.

In the soil, as also in the plant, water plays a most important part as a solvent and as an aid to chemical changes. Generally speaking, hot water dissolves materials better than cold; the hotter the water gets the greater its power is of dissolving. Also, if a little acid is added, many compounds otherwise insoluble dissolve readily. A good illustration of this last point is shown in the ease with which water containing carbon dioxide gas (which compound is a weak acid) acts upon many minerals in the soil and dissolves them, though pure water does not dissolve them at all.

In view of the special importance of certain elements and their compounds in gardening, a few short notes on these are given below. For further particulars, reference must be made, however, to some book on systematic chemistry.

Oxygen.—This element (a gas existing in air) is of first importance, as it enters so easily into combination with other elements. When carbon burns, it combines with oxygen and yields carbon dioxide gas. When an animal breathes, it takes in oxygen and gives out carbon dioxide gas. A plant, however, takes in carbon dioxide gas and gives out oxygen; and in the soil oxygen from the air produces or assists in the production of new compounds. Hence the wisdom of rough digging in the winter to expose as large an area of the soil to the air as possible.

Nitrogen.—This is the element which makes up practically four-fifths of the air. It differs very markedly from oxygen in that it is, whilst in the free state, an inactive gas. When combined with other elements nitrogen gives rise to very different substances, some of them most active, *e.g.* aqua fortis (nitric acid), ammonia, etc., whilst others, such as nitrate of soda and nitrate of potash, are of great importance to the plant and the animal. Both plants and animals require nitrogen, and as it is only the leguminous plants which have the power of using nitrogen gas, the use of nitrogenous manures, such as nitrate of soda and sulphate of ammonia, is widespread. In fact the whole group of nitrogenous manures (see article on *Manuring, Principles of*) is of fundamental interest and value.

Carbon.—This is another important element from the gardener's point of view. In a pure form carbon is seen in charcoal made from sugar. It is the compounds of carbon which are of more interest. As already mentioned, organic chemistry is nowadays regarded as dealing with the compounds of carbon.

Carbon dioxide gas, which is formed when carbon unites with oxygen, is the gas produced when coal or wood burns; also carbon dioxide is breathed out by plants and animals day and night. Also carbon dioxide gas is the source from which the plant, thanks to its green leaf and the power of sunshine, prepares sugars and starches, which are known as *carbohydrates*. Cellulose is another carbohydrate; it makes up the woody or stem portion of the plant. The carbohydrates all contain carbon, oxygen, and hydrogen.[1]

Phosphorus.—This important element is related chemically to nitrogen, and it is also a substance of great value to the plant. The element itself is of no use to the gardener, but it combines readily with oxygen, giving an oxide which dissolves in water and thus produces *phosphoric acid*. When a base is added, salts called phosphates are produced. There are many of these, some containing more acid than others. Those with the greatest amount of

[1] The last two elements are present in all carbohydrates in the proportions in which they form water. This is easily shown by adding strong sulphuric acid to one of them, as, for instance, sugar. Chemical action sets in, a mass of pure black carbon is formed, and dilute sulphuric acid (*i.e.* acid to which some water has been added) remains.—Editor.

acid dissolve in water most freely, and are thus of great value for plant life. They are known as *acid manures*. Insoluble phosphates may be made soluble by the addition of sulphuric acid, which robs the compound of part of its base, and leaves an acid phosphate (soluble) and usually an insoluble sulphate.

Other Elements.—The elements described above have all been *non-metallic*, and in the same group we include many others, such as chlorine, sulphur, silicon, and hydrogen, which are of importance, but which must be passed over here. The *metallic* elements, as the name implies, have the general properties of metals, and a few notes on some of them are given below.

Calcium.—This element occurs in limestone, which is a carbonate of calcium, and quicklime, which is calcium oxide. Liming consists of applying this element to the soil in a suitable form. See article on *Lime*.

Calcium combines readily with acids and forms salts. Those of greatest importance are included in our article on *Lime Compounds*.

Iron.—Plants require this element in order that the green colouring matter of their leaves may be properly formed. Iron salts are also used in spraying mixtures. Iron is more fully dealt with in our article *Iron and Iron Compounds*.

Magnesium is closely allied to calcium.

Potassium and Sodium.—These are two elements which form salts of great economic importance. Both elements are widely distributed, but potassium (which is abundant as a double silicate in clay) is, of course, the most important. Plants absorb potash from the soil, and when they are burnt the potash remains in their ash. In addition to its being found in clay, potash also occurs in large deposits, as at Stasfurt, from which kainit is obtained. These deposits also supply some of the impure sulphate and muriate (or chloride) of potash used as artificial fertilisers. Sodium also occurs in nature very freely, chiefly as common salt. From this caustic soda (used in spraying), carbonate of soda (or washing soda), and indeed most other compounds, can be easily made. The chief potash and soda compounds, with instructions for their use, are given in our articles on *Potash and Potassium Compounds*, and *Soda and Sodium Compounds*.

Ammonia.—This, though a compound of nitrogen and hydrogen, is regarded by chemists as if it were a metallic element, and it certainly forms many compounds with acids (such as sulphate of ammonia), of great use to the gardener. It is dealt with more fully in our article *Ammonia and Ammonium Compounds*.—W. Gdn.

See also *Education and Gardening*.

CHENOPODIUM (Goosefoot. Nat. Ord. Chenopodiaceæ).—This is a genus of hardy annual and hardy perennial plants of very little importance in gardens. Many species are troublesome weeds. *C. Bonus-Henricus* is popularly known as Mercury, Good King Henry or All-Good. It is used as a salad or vegetable, and has its culture fully described in our article on *Mercury*. Other species we must mention are *C. album*, the well-known weed Fat-Hen, described in our article on *Weeds*; *C. Botrys*, the Hind-heal; *C. hybridum*, the Maple-leaved Goosefoot; and *C. Quinoa*, the Petty Grass. For detailed descriptions of these and numbers of others, large botanical works should be consulted.

CHERLERIA.—Now included in the genus *Arenaria*.

CHERMES.—See Larch Aphis in *Insect Pests*.

CHEROKEE ROSE (*Rosa laevigata*).—See *Rose Species*.

CHERRIES : Indoor Culture.

These fruits belong to the genus *Prunus* and the Nat. Ord. Rosaceæ. They succeed in almost any form, and are most beautiful when in flower and fruit; either grown in pots as bushes, pyramids, cordons, or when planted out and trained to a trellis about 18 ins. from the glass. The soil and mode of potting is the same as recommended for Peaches; a little more bone-meal

may be added with advantage to the compost. They require firm potting, as newly-potted trees are apt to make too vigorous growth, and abundance of water is necessary.

By careful pinching the trees soon become one mass of fruiting spurs. Being subject to fly and grubs, these must be looked for and killed, or they soon destroy the crop. What might be termed forcing with fire-heat or anything approaching close confinement is fatal to the crop. All that is needed is a constant circulation of air, with 40° F. at night and 50° F. by day, rising to 45° F. at night when the flowers open, and 55° F. by day, which should not be exceeded, until stoning has passed. A gentle warmth in the pipes is beneficial during the flowering period, and fertilisation of the flowers is important. *Elton*, *Guigue d'Annonay*, *Governor Wood*, and *Mayduke* are excellent pollen producers. Frequently syringe the trees during the time the fruits are swelling, but not when in flower or during the ripening of the fruit. All the varieties do well in pots, and the plants should be removed to the open air as soon as the fruits are gathered, and potted into larger pots as soon as the wood shows signs of changing for ripening.

Varieties.—*Bigarreau de Schreken.*—A very fine early black.

Black Tartarian.—A large and handsome fruit, and great bearer.

Early Rivers.—An excellent hardy early variety.

Emperor Francis.—A fine late variety.

Geant de Hedelfingen.—A large black of fine flavour.

Napoleon.—An excellent late variety.

Besides the above, many other good varieties might be included with advantage in large collections.

F. J.

CHERRIES: Outdoor Culture. These fruits are not well suited for small gardens, as standard trees take so much room and shade other crops, and birds often get all the fruit before it is fully ripe. They may be grown to perfection on a wall with east aspect, as in that position they can be netted. The Cherry resents pruning, and the trees "gum" where cutting is done, so that all regulating of shoots should be done when in full growth, so that the wound can heal over. For general hints on planting, etc., reference should be made to our article on *Fruit Culture*, *Hardy: General Considerations*.

Varieties.—A good selection for walls or fences is given below:—

Black Tartarian (Circassian).—Very large; the latest of all. Rich flavour.

Frogmore Bigarreau.—Red and yellow, mid-season variety. Profuse bearer,—rich and sweet.

Governor Wood.—Pale red and yellow. Very thin skin. Rich flavour. Free bearer.

Napoleon Bigarreau.—Very large, late red and yellow: the best late pale cherry.

River's Early.—Black. Profuse bearer, of weeping habit. Rich and delicious, lasting a long time in perfect condition.

Waterloo.—Black, rather late. Considered the best flavoured of all. Good bearer.

Should it be desired to have Standard Cherries, *Frogmore* and *Waterloo* are the best, but *Mayduke* is more compact in growth. The fruit of this is rich purple, and is ready early.

The Morello makes a good small standard, and is grand as a bush also.—G. B.

CHERRY.—See *Cherries*, and under Prunus in *Trees*.

CHERRY BIRCH (*Betula lenta*). — See *TREES*.

CHERRY GUMMING.—See GUMMOSIS in *DISEASES OF PLANTS*.

CHERRY LAUREL (*Prunus Laurocerasus*).—See *TREES*.

CHERRY LEAF SCORCH.—See *DISEASES OF PLANTS*.

CHERRY PIE.—A synonymous English name for HELIOTROPE.

CHERRY PLUM (*Prunus cerasifera*).—See *TREES*.

CHERRY SCAB.—See *DISEASES OF PLANTS*.

CHERVIL. — See *ANTHRISCUS* and *SALAD PLANTS*.

CHESHIRE PRUNE.—See *DAMSONS AND BULLACES*.

CHESTNUT.—See *NUT CULTURE*. See also the genus ÆSCULUS in *TREES*.

CHESTNUT OAK (*Quercus Prinus*).—See *TREES*.

CHICKASAW PLUM (*Prunus angustifolia*).—See *TREES*.

CHICKLING VETCH (*Lathyrus sativus*).—See *LATHYRUS*.

CHICKWEED.—A troublesome annual weed. See *WEEDS*.

CHICKWEED WINTER-GREEN (*Trientalis europaea*).—See *TRIENTALIS*.

CHICORY. — See *CICHORIUM*, *MEDICINAL HERBS*, and *SALAD PLANTS*.

CHILDREN'S GARDENING.

This is too big a subject to launch upon in the present edition excepting in its side branch *SCHOOL GARDENING*, on which a separate short article appears. We recommend parents who are interested in encouraging a taste for gardening in their young folks to get *The Children's Book of Gardening*, by Mrs. Alfred Sidgwick and Mrs. Poynter, published at the office of this Dictionary.

CHILE SALTPETRE.—See SODIUM NITRATE in *SODA AND SODIUM COMPOUNDS*.

CHILI.—See *SALAD PLANTS*.

CHILI NETTLE (*Loasa lateritia*).—See *LOASA*.

CHILI PINE (*Araucaria*).—See *TREES*.

CHILIAN ARBOR VITAE (*Libocedrus chilensis*).—See *TREES*.

CHILOCHLOA.— Now included in the genus *PHLEUM*.

CHIMNEY BELLFLOWER (*Campanula pyramidalis*. Nat. Ord. Campanulaceæ).—Although a short-lived perennial, the Chimney Bellflower does best when grown as a biennial. Well-grown plants form pyramids of bloom 3–5 ft. high during the July and August of the second year from seed. Numerous side branches from the base get nearly as tall as the central stem. The flowers are of some shade of light blue, and pure white in the variety *C. p. alba*. Seeds may be sown in the open in May, or in boxes in a cold frame during May, June, or July, the sooner the better to get strong plants before autumn. Transplant the seedlings as soon as they are fit to handle, in order not to delay growth. They may be put in their flowering positions in borders at the time of transplanting or in October. At that time large plants may be potted in 7-inch or 8-inch pots to bloom in the greenhouse the following year. Keep them in a cold frame during winter. Use a compost of good loam, some well-rotted manure, and sand, and feed with weak liquid manure when the flower stems begin to develop.

What to Grow. — Below is a selection of the best sorts:—

Campanula pyramidalis.—A blue sort, flowering in July and August. Height, 3–5 ft.

C. p. alba.—A white sort, flowering in July and August. Height, 3–5 ft.

C. p. compacta.—A deep blue sort, flowering in July and August. Height, 3 ft.

C. p. compacta alba.—A white sort, flowering in July and August. Height, 3 ft.—J. F.

CHIMONANTHUS. — For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

CHINA ASTER.—See *ASTER.*

CHINA ROSES.—For the best varieties see *ROSE CLASSES.*

CHINCAPIN OAK (*Quercus prinoides*). See *TREES.*

CHINESE ARBOR VITAE (*Thuya orientalis*).—See *TREES.*

CHINESE ARTICHOKE (Syns. CROSNES, JAPANESE ARTICHOKE, STACHYS, etc.) (*Stachys Sieboldi.* Nat. Ord. Labiatæ).—This somewhat peculiar-formed vegetable is but little known to English gardeners, many not being aware of its existence. Others, having to provide a large and varied supply of fresh vegetables, find in this a useful addition to the none too large variety of winter vegetables, while many first-class cooks find the tubers of great value for soup, and for what are termed "made dishes."

Culture.—Early April is soon enough to plant. Allow not less than a foot between the rows, and 8–9 ins. between the sets, each of these being buried with about 4 ins. of soil. A light loam is better than a strong clay, but the latter will give good returns if dressed with ashes.

During the summer months the space between the rows should be kept free from weeds, but even in the driest times, artificial watering need not be resorted to. Like the more popular Jerusalem Artichoke (or, as many men term it, Sunroot), these do not attain full size until the end of the growing season. They may, however, either be left in the ground to be dug as required, or lifted and stored in boxes of sand or ashes. A good covering is essential, since the roots, on full exposure to light and air, very soon lose their culinary value, and they are then useful only as food for fowls or pigs.—F. R. C.

CHINESE BELLFLOWER.—A name applied to *PLATYCODON,* which see.

CHINESE CABBAGE (*Brassica sinensis.* Nat. Ord. Cruciferæ).—This is a native of China, where it is known as the Pak-choi. Although a true Cabbage, in appearance it more resembles the Endives and Lettuces than our Cabbages, Kales, and Broccolis.

It has, for a long time, been popular in France, Italy, and Southern Europe, but has not made headway in England and has not been cultivated to any extent before the beginning of this century.

Culture.—Coming, as it does, from China, this vegetable is fond of a mild climate and cannot be safely recommended for growing in more exposed northern places, such as Scotland, or, indeed, the north-eastern counties of England. In the South and West of England, South Wales, and in the South and West of Ireland, the Chinese Cabbage may be easily and successfully cultivated by the average gardener or amateur.

The type—Pak-choi—is upright in growth, like a Cos Lettuce, and not unlike the Perpetual or Spinach Beet, which is grown for its leaves. The leaves are oblong, of a dark pea-green colour, and fleshy, the mid-ribs being of a creamy-white, swollen to a considerable thickness, and very succulent.

The best variety is the *Pe-tsai*, or *Improved Heading Chinese Cabbage.* This sort is leafy, vigorous in growth, and self-blanching: it can easily be grown about 3–4 lb. in weight. It should not be sown before about the end of July for winter use, otherwise it quickly runs to seed. A light, porous soil suits it best, and the situation chosen for it should be a sheltered one. It should be sown in drills about 18 ins. apart, and the plants thinned out to about a foot from each other, and kept clean

and free from weeds to allow the air to play around them. In dry weather copious waterings should be given between the rows, for the leaves should never be allowed to wilt or become "leathery," brittleness and succulence being the desirable conditions of success.

In cooking it as a vegetable for table, it is better steamed, with a small piece of butter in the bottom of the pan. In France the leaves alone are often boiled like Cabbage, while in England the mid-ribs are most frequently cooked and served up like Asparagus.

Pe-tsai makes an excellent salad, and, as a variation from Lettuce and Endive, is a desirable adjunct to the salad-bowl. The quicker it is grown the better, it being then more tender and succulent. The richer the soil, therefore, and the warmer the situation, the better will be the result.—A. H.

CHINESE CHERRY (*Prunus japonica*). See *TREES*.

CHINESE CHESTNUT (*Æsculus chinensis*).—See *TREES*.

CHINESE JUNIPER (*Juniperus chinensis*).—See *TREES*.

CHINESE LARCH.—A name applied to the genus PSEUDOLARIX. See *TREES*.

CHINESE PRIMULA (*Primula sinensis*).—See *PRIMULA*.

CHINESE QUINCE (*Cydonia sinensis*). See *SHRUBS*.

CHINESE WISTARIA (*Wistaria chinensis*).—See *CLIMBING AND TRAILING PLANTS*.

CHIONANTHUS.—For the best species see *SHRUBS*.

CHIONODOXA (GLORY OF THE SNOW. Nat. Ord. Liliaceæ).—This is a genus of pretty little blue, or blue and white, flowering plants, growing about 6–10 ins. in height, and blooming in early spring just before the blue squill or *Scilla sibirica*. They are useful for edgings, for clumps in borders or rockwork, or for naturalising in short grass.

Culture.—Any good garden soil suits them, but as they do not like being disturbed, newly bought bulbs seldom do themselves justice at their first time of blooming. If possible so arrange matters that Chionodoxas can be left undisturbed for a number of years. They seed very freely, and unless the seed pods are picked off before they ripen and burst, an infinite number of tiny seedlings will soon appear, and these, once they have got a foothold, are very difficult to eradicate. If there is no objection to these pretty little blue flowers coming up "all over the place," leave the seed pods alone, and nature will do the rest. Then, in a few years' time, borders may be dug and re-dug, without doing much harm to the Chionodoxas. A certain number are sure to survive and bloom.

Species and Varieties.—*Chionodoxa gigantea*[1] has generally only two or three large flowers on a stem; in colour these are mauvey-blue. Sometimes pure light blue forms are met with. There is also a white on the market, but it is hard to get. Both forms flower in March, and average 4–8 ins. high.

C. Luciliae has blue flowers in March which have a prominent white eye. Its variety *Tmoli* has deeper coloured flowers and blooms in April. There is also a white form, but it is very scarce. They average 6–10 ins. high.

C. sardensis[2] is one of the best of all early spring flowering bulbs. It has deep, rich blue flowers without

[1] This is regarded as a species by gardeners and horticultural traders, but in reality it is the variety *gigantea* of *C. Luciliae*.—EDITOR.

[2] This is regarded as a species by gardeners and horticultural traders, but in reality it is the variety *sardensis* of *C. Luciliae*.—EDITOR.

any white in the eye as in *C. Luciliae*, which are freely produced in March. It grows 6–8 ins. high.—J. J. & E.

CHIP TOP-DRESSINGS.—See *TOP-DRESSING.*

CHITTAM WOOD (*Rhus cotinoides*).—See *SHRUBS.*

CHIVES.—See *SALAD PLANTS.*

CHLORA (Nat. Ord. Gentianaceæ). This is a genus of about eight pecies of plants which are not quite hardy. On light sandy soils they behave as annuals, but in more genial mediums (especially if sown late out of doors) they flower the second year and thus behave as biennials.

Probably the best way of raising them is to sow the seeds in pots in a cold frame in March or April and plant out in May, though seeds may also be sown outside on the rockery or in the open borders in April.

We recommend the following :—

Chlora grandiflora.—This bears flat-topped trusses of yellow flowers of considerable beauty from June to July, and averages 6–12 ins. in height.

C. imperfoliata.—This is not so attractive as the last, but bears useful bright yellow flowers from June to August, and grows 12 ins. high.

C. perfoliata (YELLOW CENTAURY). —This is probably the best known sort, with its brilliant yellow flowers in July and August, on plants 12–18 ins. high.

C. quadrifolia.—This is another useful sort bearing yellow flowers from June to August, and growing 12 ins. in height.—J. F.

CHLORATE OF POTASH.—See POTASSIUM CHLORATE in *POTASH AND POTASSIUM COMPOUNDS.*

CHLORIDE OF AMMONIA.—See AMMONIUM CHLORIDE in *AMMONIA AND AMMONIUM COMPOUNDS.*

CHLORIDE OF CALCIUM.—See CALCIUM CHLORIDE in *LIME COMPOUNDS.*

CHLORIDE OF LIME.—See CALCIUM HYPOCHLORITE in *LIME COMPOUNDS.*

CHLORIDE OF MAGNESIA (MAGNESIUM CHLORIDE).—A reference to this is made in *MAGNESIA AND MAGNESIUM COMPOUNDS.*

CHLORIDE OF POTASH.—See POTASSIUM CHLORIDE or MURIATE in *POTASH AND POTASSIUM COMPOUNDS.*

CHLORIDE OF SODA.—See SODIUM CHLORIDE in *SODA AND SODIUM COMPOUNDS.*

CHLORIS (GREEN GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy and half-hardy grasses not suitable for general garden purposes, and thus to describe species would be beyond our scope. *C. barbata* and *C. elegans* are pretty bouquet grasses used by some nurserymen, but we should prefer to use LOVE GRASS (*Eragrostis elegans*), described under the latter name in our article on *ORNAMENTAL GRASSES*, for this purpose.

CHLOROSIS. — See *DISEASES OF PLANTS.*

CHOICE OF SITE FOR GARDENS.—The geological aspect of this matter is briefly outlined in *GARDEN GEOLOGY.*

CHOISYA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

CHOKE-BERRY (*Pyrus arbutifolia*).—See *TREES.*

CHOKE CHERRY (*Prunus virginiana*). See *TREES.*

CHONDROSEA.—Now included in the genus *SAXIFRAGA.*

CHOU DE BURGHLEY (*Brassica Hybrid.* Nat. Ord. Cruciferæ).—This is one of the most useful additions to the list of winter vegetables, but up till now it appears to be but little grown by the amateur or small grower, yet it is to such as these the plant has special recommendations. Now that the true value of fresh vegetables is becoming more fully

recognised, we may expect this plant to receive the attention it deserves.

In appearance this is quite distinct from the ordinary winter greens, combining the qualities of a Cabbage and Broccoli, being equal in hardiness to the first-named, but the large leaves enclose the head of a Broccoli and thus protect it. Every part of the plant may be eaten, the green leaves being of a decidedly better flavour than ordinary Cabbage.

Culture.—Seed should be sown in the open garden towards the end of March, a rich seed-bed being equally as important as thin sowing. When the young plants have grown 6 or 7 ins. high, it will be better to transfer them to a temporary nursery bed rather than risk ruination of the crop through weak growth resulting from an overcrowded seed-bed. As the plants are less able to withstand severe frost than the more common Kales, the importance of short sturdy growth can hardly be over-estimated.

The summer quarters for the plants should be well manured, and the soil dug to a good depth. Not less than 30 ins. between the rows should be allowed, and whenever possible the same distance between the plants, giving copious waterings during dry weather. At the approach of severe frost, protect all heads which are rapidly developing Broccoli inside with tufts of hay, straw, or paper.—F. R. C.

CHRIST'S THORN.—The genus PALIURUS. See *SHRUBS*.

CHRISTMAS DAISY (*Aster grandiflorus*).—See footnote to article on *ASTER*.

CHRISTMAS ROSE (*Helleborus niger*). See *HELLEBORUS*.

CHRYSALIDOCARPUS.—For the best species see *PALMS*.

CHRYSANTHEMUM (Nat. Ord. Compositæ).—**Annual Species.**—These, *i.e.* the CORN MARIGOLDS and CROWN DAISIES, may easily be raised from seeds sown out of doors in March or April, but the garden varieties are more usually treated as half-hardy annuals and raised from seed sown in heat in January or February. The following are worthy of inclusion in every garden :—

Chrysanthemum carinatum.—This bears white and purple flowers through the summer, and averages 2 ft. in height.

C. coronarium.—This bears yellow flowers throughout the summer and autumn, and grows 2–3 ft. high.

C. multicaule.—A dwarf yellow summer flowering species, averaging 1 ft. high.

C. segetum.—This is a bright yellow continuously summer flowering sort, averaging 1½ ft. in height.

C. viscosum.—This also is a yellow summer flowering sort, averaging 1½ ft. in height.

Perennial Border Species.—Certainly the hardy perennial Chrysanthemum, or OX-EYE DAISY, is one of our easiest border flowers to grow, succeeding anywhere in good soil in a sunny site. Most sorts are splendid for cutting, lasting well in water. They come into bloom early, though usually considered autumn flowers, and continue for a long period, a single plant often giving a hundred or more blooms. Propagation is most easily effected by division of the roots in the autumn or spring, but seed may also be sown in the spring or early summer. Out of the numerous species and varieties we give a selection of the best below :—

Chrysanthemum coccineum (Syns. *Pyrethrum coccineum* and *P. roseum*).—This is an attractive scarlet sort blooming from June to September, and averaging about a yard high. From it are derived the handsome border plants described in our article on *PYRETHRUM*.

C. grandiflorum.—A biennial or semi-perennial species, with yellow flowers produced in the summer. Height, 2–3 ft.

C. lacustre (MARSH OX-EYE DAISY).—This is an autumn blooming species similar to *C. maximum*, but requiring a moister situation.

C. Leucanthemum (OX-EYE DAISY).—This is well known, with its white flowers borne from June to early August. Its height is 2 ft.

C. maximum (OX-EYE or SHASTA DAISY).—This is the species most frequently cultivated, and of which there are now numerous varieties, such as *King Edward VII., Mrs C. Lothian Bell, Mrs Head, Prince Henry, Maurice Pritchard, Snowdon, The Speaker, Rev. H. Sanders, Mrs J. Tersteeg*, etc. The size of the flower varies greatly. The old *Dr Hogg*, for instance, had flowers 1½–2 ins. across, but the blooms of *Maurice Pritchard* are often 4 ins. across and sometimes more. The flowering period of the varieties of this species is a long one, extending from June to late October, while the height varies from 2 ft. to 1½ yds.

C. uliginosum (Syn. *Pyrethrum ulginosum*).—This, the GRAND OX-EYE DAISY, is an autumn blooming species with white flowers. Its height is 5–6 ft.

Rock Garden Species.—The above Perennial Border Species are too coarse for the rock garden. The two species described below are, however, well worth growing. They thrive in deep, well-drained soil, and are propagated by division of the roots in the autumn or spring.

Chrysanthemum alpinum.—This is a small tufted plant. Flowers white. Site sunny. Soil deep gritty. Flowering Period, June to July. Height, 4 ins.

C. arcticum.—This is similar to the above but larger. Flowers white, though tinged lilac. Site, half-shade. Soil deep gritty. Flowering Period, August to September. Height, 9 ins.

See also FEVERFEW in *MEDICINAL HERBS*, and *PYRETHRUM*.

CHRYSANTHEMUM MILDEW.—See *DISEASES OF PLANTS*.

CHRYSANTHEMUM RUST.—See *DISEASES OF PLANTS*.

CHRYSANTHEMUMS, CULTIVATION OF.—In the British Isles the Chrysanthemum, botanically termed *Chrysanthemum sinense*, has been aptly termed "The Queen of Autumn," and again, "The Autumn Queen" or "Autumn Glory." It is a general favourite, because it embraces so many types and varieties, and while it responds in a remarkable way to skill and attention in culture, yet is wonderfully patient of neglect, plants often flowering freely in autumn after weeks of inattention. Coming into bloom in the dull season when flowers are scarce, the handsome plants adorn the greenhouse for several weeks, providing a display unequalled by any other subject of cultivation.

Propagation.—This is carried out in winter and early spring by means of cuttings obtained from basal growths which emerge from the roots after the parent plant has grown to maturity. The cuttings strike root readily in a temperature of about 50° F., and in from six to eight weeks are ready to be transplanted. The greenhouse varieties, which flower in October, November, and December, are usually grown in pots throughout the season, so that after the cuttings have struck root they require to be potted on into larger-sized pots, continuing this process about every six weeks until the end of June, by which time the plants should be in 8-inch pots. They then need all the light and air possible, and an exposed situation in the garden should be

chosen. Bamboo stakes should be inserted at the final potting, since the plants grow tall as a rule and need support.

During the month of July careful attention is necessary to provide a plentiful supply of water, and towards the end of the month a little stimulant may be added to the water. In August the flower-buds form, and, to secure early blooms, the side-growths which emerge from the base of the buds must be removed. As the flower-buds begin to swell up, manure water and weak soot water may be given with increasing frequency as time goes on. By the middle of September the greenhouse or conservatory should be in readiness to receive the plants. There is always much danger of harm from frost, and boisterous wind and heavy rain should be avoided at this stage. Any plants which are showing the colour of the petals must be housed in good time, but the later-flowering varieties, and Singles which flower on terminal sprays, may be left out for another week or two if the weather is open.

Groups or Types.—Chrysanthemums may be divided into two main groups: first, the outdoor or early-flowering varieties; and secondly, the indoor or late-flowering varieties.

OUTDOOR CHRYSANTHEMUMS have been improved to a wonderful degree within the last few years, and there is now a host of varieties of every hue, some flowering in early August, others in September, and quite a number in October; but these latter often require shelter to preserve them from rain and frost. In addition to the double-flowering outdoor varieties there are many charming single-flowering sorts which are useful for garden decoration, or as cut flowers. The Pompons are popular for outdoor culture, and nothing can excel them for hardiness, as they survive the worst weather, coming up with remarkable vigour every spring. The outdoor varieties are propagated in the same way as the indoor kinds, namely, from cuttings; but the plan more generally adopted is to divide up the old stools in March, selecting young growths with roots attached and throwing away the remainder. These young plants, put into well-prepared ground in a fairly open situation, will grow freely during the summer if given water occasionally in hot weather, and a mulching of short stable manure in July will assist in building up good blooms for a display in August or September, according to the variety.

INDOOR or LATE-FLOWERING varieties may be divided into several sections. Firstly, we have the large Double-flowering exhibition Chrysanthemum, generally called the "Japanese"; some have incurving petals, others with the petals reflexed. Secondly, there is a numerous class known as Decorative varieties, similar in many respects to the exhibition Japanese, but more adapted for yielding a quantity of medium-sized flowers rather than two or three monster blooms on a plant. The Incurved varieties are largely grown for their shapely blooms, the petals all curving in to the centre, so that it is the back of the petals which is visible. Then there is the Single-flowering type, which is now very popular and bids fair to outrival all the other kinds for lightness and graceful decorative effect. Large single blooms may be obtained with a diameter of from 6–7 ins. by disbudding, medium-sized blooms by thinning other varieties moderately; while yet there are some varieties which must be allowed to grow quite naturally, the result being that they form a bush

covered with sprays of small star-shaped blooms. The single form of the Chrysanthemum yields nothing to the double types in variety of colouring, while many of the varieties are sweet-scented, the perfume reminding one somewhat of honey. The Pompons and Anemone Pompons are delightful in every way, and are worthy of inclusion in any collection. Then there is a type which finds favour with those who are fond of quaintness—the feathery, spidery, and thread-petalled varieties.

When all of the types are represented in a large collection the effect is wonderful.

To Get New Sorts.—New varieties are obtained by sowing seeds saved from plants which have been properly cross fertilised with other varieties. Seeds sown in February in a genial temperature in the greenhouse will flower the same season in November, so that the raiser has not long to wait to see the result of his attempt to add to the list of varieties. If the novelty thus raised finds favour, the raiser, of course, has the privilege of naming it. The "singles" are very easy to propagate from seed; so much so, that many nurserymen offer packets of seed every winter at low prices. Of course in these packets the seeds are not likely to produce valuable novelties, although occasionally such is the case, and the grower finds it worth while to perpetuate a promising plant.

New varieties are also obtained by means of "sports"; that is, a plant occasionally develops a different coloured flower on one stem to those on the remainder of the plant. Cuttings are obtained from the sportive stem, and the new colour is thus perpetuated under another name. A variety named *Caprice du Printemps* has yielded quite a number of "sports" in this way, and they are designated *Bronze Cap, Red Cap, White Cap*, etc.

The Chrysanthemum has many enemies, which, if allowed to carry on their ravages unchecked, will rob the grower of all prospect of success. In the early stages the green fly and the leaf miner are the worst enemies. For methods of dealing with these pests, see article on *Insect Pests*.

The Chrysanthemum is heir to two very insidious diseases in summer, which, if not taken in time, are very dangerous to the life of the plant. "Fungus," which attacks the underside of the lower leaves, assumes the form of rusty-brown rings, which increase and spread until the foliage goes off entirely as if it had been scorched by fire. "Rust" is another disease, which is very similar in character to "Fungus," but is caused by overcrowding chiefly, whereas the other disease will appear in the best regulated garden, where everything is done to ensure the good health of the Chrysanthemum plants.

[Mildew is also troublesome, especially in the earlier stages of growth.—Editor.]

For preventative measures, see article dealing with *Diseases of Plants*.

It will be seen from the above brief description of the Chrysanthemum that the culture has vast possibilities for the beginner, and the enthusiastic amateur is always welcomed into the ranks of Chrysanthemum growers.

Selection of Sorts.—The varieties now in cultivation are almost legion, owing to propagation from seed offering so little difficulty, and also to the fact that the Royal Horticultural Society and the National Chrysanthemum Society both offer inducement to raisers of useful novelties. The beginner is positively bewildered at first blush to know

what to start with, but the specialists who offer plants for sale will as a rule give advice willingly on the subject of forming a collection of varieties of easy culture for an initial start. The autumn flower-shows, both local and central, are very educational, as all the choicest varieties are there seen at their best. Lists, if given here, would be of very little use, as varieties become so quickly out of date. Hence readers are referred to raisers or Chrysanthemum specialists.—JAS. C.

CHRYSANTHEMUMS, Historical Notes on.—This popular autumn flower has been grown from time immemorial. The beautiful exhibition and garden varieties are the result of long ages of cultivation, cross fertilisation, and selection by Oriental gardeners, who from *C. sinense* succeeded in obtaining those varieties first introduced into Europe towards the close of the eighteenth and beginning of the nineteenth centuries.

Confucius, five hundred years before Christ, mentioned the flower, and many of the great classical poets of that country have referred to it in their works. Tu Fu, Po Chü-i, Ssü-K'ung T'u, eminent writers of more than a thousand years ago, speak of the Chrysanthemum in terms of high appreciation; while T'ao-Yuan-Ming, an eminent cultivator of Chrysanthemums who lived 365–427 A.D., has remained famous to this day for the success he achieved in their culture.

The flower at an early period of its existence passed over to the Isles of Japan. There it became as great a favourite as in the country of its origin. About the year 900 A.D. the Emperor Uda inaugurated the first of the Imperial Chrysanthemum Garden-parties, which have continued to be held to this day. The Chrysanthemum has also been adopted as the emblem of the highest Order of Chivalry in that country, and is rarely bestowed upon any but royal personages.

Although known in some form or other and under various names to the old European botanists, the Chrysanthemum was not introduced into Europe till 1789, when Pierre Louis Blancard of Marseilles brought from Macao the first variety (long called "the old purple") cultivated in western gardens. It was subsequently sent to Kew, and flowered for the first time in England at Colvill's Nursery, Chelsea, and was figured in the *Botanical Magazine* in 1796, see tab. 327.

Through private enterprise and the exertions of the Horticultural Society of London many new sorts were imported from the Far East, until Captain Bernet, a retired French officer, found in 1827 that the plant could be seeded in France. From that time forward many novelties were raised from seed by European growers.

The small flowering Pompon varieties are the descendants of *C. indicum*, and were the result of the introduction by Mr R. Fortune, shortly after the China War of 1842, of a variety called the CHUSAN DAISY; it is also to that intrepid botanical traveller that we owe the introduction on his second visit to the Far East twenty years later of the ever-popular Japanese varieties.

Chrysanthemum shows began to be held throughout the United Kingdom in the early "forties" of the last century, and many societies for encouraging the culture of the flower were started. To-day their number is legion, the National Chrysanthemum Society being the oldest and most influential of them all.

Early-flowering varieties were at first solely confined to the Pompon section, and appeared about the year 1850. A quarter of a century ago M. Simon Délaux of Toulouse, and other Continental raisers, brought into notice the charming free-flowering early-border varieties of Japanese form now so generally admired.

One of the most famous English growers to bring the Chrysanthemum forward in its infancy was John Salter, who was called "the father of the Chrysanthemum." Ernest Calvat was probably the most famous of the French raisers. In the United States Dr Walcott, John Thorpe, and others helped the good work along on that side of the globe; while Australia, with T. W. Pockett successfully employing his energies in raising novelties, has acquired a renown that will long remain a bright page in the annals of this far-famed flower.—C. H. P.

CHRYSEIS.—A synonym for *ESCHSCHOLZIA*, which see.

CHRYSIS.—See *ORCHIDS*.

CHRYSOGONUM (GOLDEN KNEE. Nat. Ord. Compositæ).—This is a little known hardy perennial plant not unlike the sunflower (*Helianthus*). It is useful for a shady position in the border where the collection is somewhat extensive. Plant it in March in ordinary good rich humic soil and propagate it by division of the roots or by seeds sown in the usual way in the spring.

What to Grow.—Only one species has so far come to our knowledge as being of value as a garden plant. This (*Chrysogonum virginianum*) produces yellow flowers in May and June, and averages just over 12 ins. in height.

CHRYSOPSIS (Nat. Ord. Compositæ).—This is more suitable for the wild garden than for the hardy perennial border, though it may be included in the latter. Its Daisy-like flowers make it attractive in the eyes of some, though we must confess that there are many better things. Regarding soil it is not particular; being of a strong constitution it might be more often grown in town gardens than it is, in sites where more valuable things fail. It may be propagated by splitting up the root-stocks in the usual manner in the early spring, and may be planted from November to March.

What to Grow.—In our opinion *Chrysopsis trichophylla* is one of the best of the sorts now known. This produces yellow flowers about midsummer, and averages some 12 ins. in height. *C. villosa Rutteri* is preferred by some people. It resembles *C. trichophylla* in its characters.

CHRYSOSTEMMA.—Now included in the genus *COREOPSIS*.

CHUSAN DAISY.—See *CHRYSANTHEMUMS: HISTORICAL NOTES ON*.

CICHORIUM (CHICORY. Nat. Ord. Compositæ).—This is an important genus of hardy biennial and perennial vegetables and saladings. The two best known species are *C. Endivia*, on which a separate article named *ENDIVE* appears, and *C. intybus*, the common CHICORY, dealt with in our notes on *SALAD PLANTS*, and in other articles.

See also under CHICORY in *MEDICINAL HERBS* and *SALAD PLANTS*.

CICUTA.—See *WATER HEMLOCK*.

CILIARIA.—Now included in the genus *SAXIFRAGA*.

CILIATED PINK (*Dianthus ciliatus*).—See *DIANTHUS*.

CILICIAN FIR (*Abies cilicica*).—See *TREES*.

CIMICIFUGA (Nat. Ord. Ranunculaceæ).—Many fanciful names, such as Bugbane, Bugwort, Snakeroot, and so forth, have been applied to this genus, but none are sufficiently well fixed to warrant us

treating it under its English name. We have already described the genus *Actaea* which is somewhat similar to this, and indeed *Cimicifuga foetida* is by some botanists known as *Actaea cimicifuga*.

Culture.—This is easy. The plant succeeds well in the half-shady borders in or out of the wild garden where the soil can be kept somewhat damp. It is easy to increase by seeds sown in the usual way in the spring or summer, and may also be increased by splitting up the old roots in the spring, which is the most suitable time to plant.

What to Grow.—The following may be included if space permits :—

Cimicifuga americana.—A white or yellow sort blooming in July and August, and averaging just under a yard in height.

C. cordifolia.—Similar to the above in colour and height but blooming earlier (from midsummer onwards).

C. dahurica (or *C. davurica* of some botanists and nurserymen).—This is a white sort coming out during July. Its height is about 2 ft.

C. foetida.—As remarked above by some, this is known as *Actaea cimicifuga*. Its flowers are a yellowish-white and are produced from midsummer onwards. The average height of the plant is about a yard.

C. japonica.—A white variety blooming in July and August, averaging 3 ft. in height.

C. racemosa.—This is also a white flowered sort. It blooms in July, and averages rather more than 3 ft. in height.

CINERARIA (Nat. Ord. Compositæ).—This is a genus of greenhouse herbaceous perennials and shrubs about 18–24 ins. in height —very favourite greenhouse plants, and offering a wide range of floral colour. They are easily grown from seed, and flourish in a compost of turfy loam and decayed manure, two parts each, leaf-mould one part, and enough sharp sand or charcoal chips to keep the whole sweet and open. Propagation is usually best effected by seed, though cuttings may be taken and struck in the same manner as for *Pelargoniums*, which see.

Culture.—Sow the seed from April to June at intervals of a few weeks to secure successional plants, thereby extending the flowering season. Prick out the seedlings when large enough to handle and place them in "thumbs," repotting into a larger size before the roots begin to bind. Eight-inch pots will be quite large enough for the biggest specimen plants to bloom in. Cool treatment in a frost-proof house, abundant ventilation, and occasional fumigation against aphis (see article on *Fumigating*) will ensure success.

Uses.—These plants supply greenhouse blooms when flowers are scarce. The earliest batch will come into bloom before Christmas-time, and a good show can be kept up till well on in the spring.

Varieties.—As the colours come almost true from seed, a selection can be made from high-class strains offered by several prominent seed houses.—J. L. G.

[All the hardy herbaceous perennial species of Cineraria of any importance are now included in the genus *Senecio*, on which we devote a separate article.—Editor.]

New Variety.

Cineraria Matador.—This bears rich orange-scarlet flowers with a narrow white edge and purple centre on plants of dwarf habit.

CINNA.—Now included in the genus *Muehlenbergia*.

CINQUEFOIL.—A name applied by some to *Potentilla*, which see. See also Potentilla in *Shrubs*.

CIRCAEA (Nat. Ord. Onagraceæ). This is a genus of weedy plants of no garden value, though sometimes offered in lists. *C. lutetiana* is the best known and most troublesome. It is described under its English name, ENCHANTER'S NIGHTSHADE, in our article on *WEEDS*.

CIRCASSIAN CHERRIES. — See *CHERRIES: OUTDOOR CULTURE*.

CIRCULAR BEDS, AREA OF.—See AREAS OF BEDS AND BORDERS in *ARITHMETIC AND GARDENING*.

CIRROPETALUM.—See *ORCHIDS*.

CIRSIUM.—Now included in the genus *CNICUS*.

CISTERNS.—See *TANKS AND CISTERNS*.

CISTUS.—Now correctly included in the genus *HELIANTHEMUM*. See also *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

CITRIC ACID.—See *ACIDS*.

CITY GARDENING.—See *TOWN AND CITY GARDENING*.

CITY GARDENS, ANNUALS FOR.—See *TOWN AND CITY GARDENING*.

CLADRASTIS.—For the best species see *TREES*.

CLARKIA (Nat. Ord. Onagraceæ). This genus is a small one so far as number of species is concerned, but large as regards popularity and cultivated varieties. Three species are in cultivation, all from Western North America, but there are also two Californian species not yet grown in gardens. The former, briefly described below, are hardy annuals suitable alike for the flower garden and for pot culture in conservatory decoration. At the great International Show at Chelsea, and at subsequent May shows of the Royal Horticultural Society, Clarkias have invariably produced a most effective display in seedsmen's exhibits, and such plants 2½–4 ft. high, elegant and freely flowered, are produced from an autumn sowing and by frame and greenhouse treatment. For early flowering a sowing outside in early September is advisable, but if the soil and situation are cold, the protection of a cold frame will prevent losses from slugs and from the excessive damp of our winters. The plants should be transferred to their flowering quarters in the early spring. From an April sowing outdoors or in a frame in March, a successional batch of plants to flower in late summer may be raised quite easily. Thorough thinning is desirable, and if the leading growth is pinched out a bushy plant will result. The best-named sorts are far better than mixtures, and by a careful arrangement of colours a border may be filled handsomely with Clarkias.

We here describe the three species as already promised :—

C. elegans (Syns. *C. integripetala* and *C. unguiculata* of gardens). —This bears crimson-lake coloured flowers throughout the summer, and averages 2 ft. high. Beautiful varieties are :—*Delicate Pink* (double soft pink); *Firefly* (double rosy-crimson); *Purple Prince* (double ruby-purple); *Salmon* (both double and single forms are available of this bright salmon-scarlet sort); and *Snowball* (double white).

C. pulchella (Syns. *C. elegans* (of Poir) and *C. pulcherrima*).—This is of dwarfer habit than the *C. elegans* varieties. The colour range in the flowers of modern varieties is from white to deep rose-purple; the type colour is purple. There are both double and single varieties, each eminently suitable for massing in flower borders, as the blooming period extends throughout the summer. *Brilliant Rose* (rich rose) and *Marginata* (rose, edged with white—double and single) are fine named varieties.

C. rhomboidea (Syn. *C. gauroides*). —This pink, summer flowering sort bears smaller and less attractive

flowers than those of the preceding species and varieties. Its height averages 1½ ft.

CLARY (*Salvia Sclarea*).—See *POTHERBS* and *SALVIA*.

CLASSES OF MANURES.—See *MANURES*.

CLASSIFICATION OF DAFFODILS.—See *DAFFODILS*.

CLAY.—See *SOILS: THEIR ORIGIN AND NATURE*.

CLAY COLOURED WEEVIL.—See under OTIORHYNCHUS WEEVILS in *INSECT PESTS*.

CLAY SOILS, IMPROVING.—See *SOIL IMPROVEMENTS*.

CLEANING BULBS.—See *BULBS: CLEANING AND STORING*.

CLEMATIS.—For the best species see *CLIMBING AND TRAILING PLANTS*.

CLERODENDRON.—For the best species see *SHRUBS*.

CLETHRA.—For the best species see *SHRUBS*.

CLIANTHUS (GLORY PEA. Nat. Ord. Leguminosæ).—This is an evergreen shrub which does well in pots, or planted out in a conservatory against a wall. It is propagated by cuttings in sandy soil under frame or hand-light, also by seed sown in spring. It thrives in a soil of good fibrous loam, peat, and sand. Temperature required, 40–50° F.

Greenhouse Species and Varieties:—*Clianthus Dampieri*.—Red. Flowers in March. Height, 1–2 ft.

C. puniceus.—Crimson. Flowers from May to September. Height, 2–6 ft.

C. p. albus.—White. Flowers from May to September. Height, 2–6 ft.

C. p. magnificus.—Reddish-crimson. Flowers from May to September. Height, 2–6 ft.

See also *CLIMBING AND TRAILING PLANTS*.

CLICK BEETLES.—See WIREWORMS in *INSECT PESTS*.

CLIMBERS FOR CITY GARDENS.—See under TREES AND CLIMBERS in *TOWN AND CITY GARDENING*.

CLIMBERS FOR NORTH BORDERS. See *NORTH BORDERS: SOME PLANTS FOR*.

CLIMBERS, TRAINING OF.—See *TRAINING OF PLANTS*.

CLIMBING AND TRAILING PLANTS.—In the decoration of the flower garden and in other parts of the grounds the value of plants which are of climbing or trailing habit is undeniable. Without their aid the average garden looks tame and unsatisfying; thus their judicious use cannot be too strongly advocated. It is unnecessary to dilate upon their beauty and the purposes to which they may be applied.

To cover bare walls, to clamber up poles or over rough shrubs and trees, to ramble over a trellis or arch, are only some among the many uses to which they can be put, and their proper planting and cultivation deserve greater consideration from the gardener than has hitherto been given in many places.

The term "Climbing and Trailing Plants" is an elastic one in horticulture, and has been extended to include many shrubs not naturally climbers or trailers, which are valuable for covering walls, etc., or are more satisfactory in our climate when given the protection these afford. It is impossible to give a full list of the latter here, but an endeavour has been made to select from the great number available some of the best and more useful. In this list there will be found plants of many kinds, some of twining habit, others which require to be fastened to the structure they are to adorn, and some which look best when hanging over a wall or trailing down a bank or slope in the rock garden. Some are of annual and others of perennial habit. A proportion are evergreen, but many are deciduous.

General Culture.—Brief notes are given below of the treatment specially required by each class, but some general principles of cultivation refer to all, and it will save space if these are discussed together.

The preparation of the soil for climbing or trailing plants is of the highest importance. It is self-evident that subjects which make so much top-growth call for good nourishment in the ground, and this should be provided by careful preparation. It is well-nigh impossible to err in this direction, except in the case of tender shrubs, which should not be encouraged to make too strong growths.

The soil should be well prepared by trenching and the addition of plenty of thoroughly well-rotted animal manure if this can be procured at all. Some ground bones may be added to maintain the fertility of the soil. Where only artificial manure is available, this should be given in the usual proportion for other subjects. The holes made for the reception of the plants should be at least 3 ft. across, and no pains should be spared to secure a good soil as a medium for the plants. This may consist of sound, fertile loam; if too heavy, it may be lightened by the addition of some leaf-soil or peat.

In almost every case the situation should be a sunny one, although some climbers will thrive in shaded or partially shaded positions. Ivy (*Hedera*) may be cited as an example of the latter. The situation, however, depends greatly upon the walls or other places the climbers are intended to cover.

Planting.—Many climbers can be procured from the nurseries in pots, and it is certainly preferable to obtain them thus for the convenience of planting so as to disturb the roots as little as possible. When ready to plant they should be turned carefully out of the pots. If these are filled with roots, those on the outside of the ball may be carefully put in position at the proper depth. Plants grafted or budded about the ground-level should be planted a little deeper than before.

Pruning.—Little pruning or trimming is generally needed with annuals, although some, such as the Tropaeolums of the *lobbianum* and similar types are improved by having some of the leaves removed in order to allow the flowers to be better seen. Notice should be taken as to whether they flower on the old or ripened wood or on the new growths. In the former case pruning should be confined to taking away superfluous shoots and removing decayed or weak wood. In the latter some of the old growths should be cut away, and the production of new branches encouraged.

As a general rule shrubs which flower in spring should be pruned immediately flowering is over, and autumn flowering subjects in winter or spring.

Training.—While unnatural stiffness should be avoided, it is essential to see that the plants are properly trained that they may show their beauties to the best advantage, and are neatly fastened to the wall or other support. Unless this is done in good time the effect will be greatly reduced and an air of untidiness and want of care will be apparent. Plants on walls may either be nailed, or, better still, tied to wires fixed for the purpose of training as in the case of fruit trees.

Annual Climbers.—These may be divided into two classes, hardy and half-hardy.

HARDY.—All the members of this section should be sown where

they are to bloom, giving the soil thorough preparation by deep digging and manuring. The seeds must be sown very thinly, and, if necessary, the seedlings thinned out 9–12 ins. apart according to the vigour of the subject. It is not always convenient to sow the seeds where the plants are to bloom, and in this case they may be sown under glass, and the seedlings treated in the same way as half-hardy annuals, for which see separate article on *Annuals for all Purposes*, and paragraph below.

Half-Hardy.—Those belonging to this section should be sown in slight heat in spring at the usual time for half-hardy annuals, and only require the general treatment recommended for them. They can be planted out in late May or the beginning of June. It is generally more satisfactory to put the young plants singly into small pots after the first pricking off, and if the pots become filled with roots before the time for planting out, to shift them into larger ones and to plant with the ball intact.

Perennial Climbers.—These likewise may be divided into hardy and half-hardy sorts. They are generally propagated by seeds, cuttings, or layers. As propagation by these methods is treated of elsewhere in this work (see article on *Propagation of Plants*), it is unnecessary to give details here.

Hardy.—These are usually of easy culture, but it is necessary for their well-being that they should be liberally nourished both by proper preparation of the soil before planting and when they are growing strongly. Established plants are greatly helped by giving them occasional supplies of weak manure water, and, in dry weather, also by complete soakings with pure water at intervals. They are greatly benefited, too, by the annual removal of a little of the surface soil and replacing it with fresh compost together with a mulch of animal manure where this would not be offensive, or dressings of an artificial fertiliser. Training and pruning must be carefully attended to at the proper seasons. See articles on *Pruning Roses and Shrubs*, and *Training of Plants*.

Half-Hardy.—Generally speaking, these require the same treatment as that for the hardy sorts. They must, however, be protected in the winter. A common error in doing this is to cover the plants too closely, with the result that premature growth is induced before the coverings are removed, and when they are taken off injury is frequently caused by spring frosts. Spruce and other coniferous branches are excellent for covering them, and scrim or comparatively open mats are better than close canvas or sacking.

Shrubby Climbers.—Many plants not properly of climbing habit are employed for covering walls or trellises, and it is advisable to give a selection of these. They may be divided into Hardy Deciduous, Half-Hardy Deciduous, Hardy Evergreen, and Half-Hardy Evergreen plants. The treatment advocated above applies to them also. It must be noted that the division into hardy and half-hardy plants is somewhat arbitrary, as plants hardy in some localities may be only half-hardy in others, and *vice versa*.

What to Grow.—In the following selection only some of the best sorts are named, and in some genera the number of species and varieties is so great that they cannot be fully enumerated; hence readers are referred to the lists of the leading nurserymen.

In the different sections, shown by the initials inserted in brackets, *H.A.* stands for Hardy Annual; *H.H.A.* for Half-Hardy Annual; *H.D.* for Hardy Deciduous Perennial; and *H.H.D.* for Half-Hardy Deciduous Perennial; *H.E.* for Hardy Evergreen; and *H.H.E.* for Half-Hardy Evergreen.

Abelia chinensis (*H.H.E.*).—The ROCK ABELIA, with pink flowers in September. Height, 5 ft.

A. floribunda (*H.H.E.*).—The FLORIFEROUS ABELIA, with pink flowers in September. Height, 4 ft.

Abutilon megapotamicum (Syn. *A. vexillarium*, *H.H.D.*).—The BIG RIVER ABUTILON, with scarlet and yellow flowers from June to August. Height, 5 ft.

A. vitifolium (*H.H.D.*).—The VINE-LEAVED ABUTILON, with mauve flowers in August. Height, 12 ft.

Aconitum volubile (*H.D.*).—The CLIMBING MONKSHOOD, with blue flowers in August. Height, 9 ft.

Actinidia Kolomikta (*H.D.*).—White flowers in June. Height, 10 ft.

Akebia quinata (*H.D.*).—The FIVE-LEAFLETED AKEBIA, with purple-brown flowers in March. Height, 9 ft.

Ampelopsis. See *Vitis*.

Aristolochia Sipho (*H.D.*).—The DUTCHMAN'S PIPE, with yellowish and brown flowers in July. Height, 30 ft.

Atragene. See *Clematis*.

Azara Gilliesii (*H.E.*).—Yellow flowers from November onwards. Height, 15 ft.

A. microphylla (*H.E.*).—The SMALL-LEAVED AZARA, with greenish-yellow flowers in May. Height, 20 ft.

Berberidopsis corallina (*H.H.E.*).—The CORAL BARBERRY, with red flowers in June. Height, 20 ft.

Berberis. See article on *SHRUBS*.

Berchemia volubilis (*H.D.*).—The TWINING BERCHEMIA, with white flowers in June. Height, 15 ft.

Bignonia capreolata (*H.H.D.*).—The TENDRILLED TRUMPET FLOWER, with red and yellow flowers in April. Height, 15 ft. See also *Tecoma*.

Buddleia Colvillei (*H.H.E.*).—Rose flowers in July. Height, 20 ft.

B. globosa (*H.H.D.*).—The ORANGE BALL TREE, with orange flowers from May onwards. Height, 15 ft.

B. variabilis (*H.D.*).—The VARIABLE BUDDLEIA, with purple flowers in July. Height, 20 ft. Its variety *Veitchiana* bears purple-mauve flowers, but is otherwise similar.

Calystegia hederacea fl. pl. (Syn. *C. pubescens fl. pl.*, *H.D.*).—The DOUBLE BINDWEED, with rose flowers from June to August. Height, 6 ft.

Camellia japonica (*H.E.*).—The well-known CAMELLIA, with white to crimson flowers from March onwards. Height, 20 ft.

Carpentaria californica (*H.D.*).—The CALIFORNIAN CARPENTARIA, with white flowers in July. Height, 10 ft.

Ceanothus americanus (*H.D.*).—The NEW JERSEY TEA, with white flowers in June. Height, 8 ft.

C. azureus (*H.D.*).—The BLUE MOUNTAIN SWEET, with blue flowers in June. Height, 10 ft.

C. hybridus (*H.D.*).—The HYBRID MOUNTAIN SWEET, in many varieties from white to blue and red, flowering in June. Height, 10 ft.

Celastrus articulatus (*H.D.*).—The STAFF TREE, with pale yellow flowers in July followed by bright berries. Height, 10 ft.

C. scandens (*H.D.*).—The BITTER SWEET, with pale yellow flowers in July, succeeded by red and yellow berries. Height, 10 ft.

Chimonanthus fragrans (*H.D.*).—The WINTER SWEET, with yellowish flowers from December onwards. Height, 6 ft.

Choisya ternata (*H.E.*).—The

MEXICAN ORANGE FLOWER, with white flowers from June to September. Height, 8 ft.

Cistus (*H.D.* or *H.H.E.*).—ROCK ROSE. This is now correctly included in the genus *Helianthemum*; some of the better known species will be found in our article on *SHRUBS*.

Clematis alpina (Syn. *Atragene alpina*, *H.D.*).—The ALPINE CLEMATIS, with blue flowers in summer. Height, 10 ft.

C. coccinea (*H.D.*).—The SCARLET CLEMATIS, with scarlet flowers in summer. Height, 8 ft. Its variety *hybrida* is available in many colours, and blooms in July. Height, 8–10 ft.

C. Flammula (*H.D.*).—The FLAME CLEMATIS, with white flowers from July onwards. Height, 20 ft.

C. florida (*H.D.*).—The FLORID CLEMATIS, with white flowers in April. Height, 10 ft. Its variety *hybrida* is available in many double and single colours, but is otherwise similar. See nurserymen's catalogues for selection.

C. Jackmani (*H.D.*).—JACKMAN'S CLEMATIS, with purple flowers from August to October. Height, 20 ft. Its variety *hybrida* is available in many colours, as described in nurserymen's lists, but is otherwise similar.

C. lanuginosa (*H.D.*).—The WOOLLY CLEMATIS, with blue flowers from June to August. Height, 10 ft. Its variety *hybrida* is available in many colours, single and double, as described in trade lists, but is otherwise similar.

C. montana (*H.D.*).—The MOUNTAIN CLEMATIS, with white flowers in May. Height, 20 ft. Its varieties *grandiflora* and *rubens* bear white and rosy-purple flowers respectively, but are otherwise similar.

C. orientalis (*H.D.*).—The STRONG-SMELLING CLEMATIS, with yellowish-green flowers in summer. Height, 20 ft.

C. patens (*H.D.*).—The SPREADING CLEMATIS, with white flowers from June onwards. Height, 10 ft.

C. tangutica (Syn. *C. orientalis tangutica*, *H.D.*).—The BRIGHT YELLOW CLEMATIS, with golden-yellow flowers in July. Height, 10 ft.

C. Vitalba (*H.D.*).—The well-known OLD MAN'S BEARD or TRAVELLER'S JOY, with white flowers in July. Height, 20 ft.

C. Viticella (*H.D.*).—The VINE BOWER CLEMATIS, with blue or purple flowers from June onwards. Height, 20 ft. Its variety *hybrida* is available in many colour forms as described in nurserymen's lists, but is otherwise similar.

Clianthus puniceus (*H.E.*).—The GLORY PEA, with crimson flowers in July. Height, 5 ft.

Cobæa scandens (*H.H.A.*).—The CLIMBING COBÆA, with violet or white flowers in July. Height, 20 ft.

Cornus capitata (Syn. *Benthamia fragifera*, *H.H.E.*).—BENTHAM'S STRAWBERRY TREE with green and yellow flowers in June. Height, 10 ft.

Corylopsis spicata[1] (*H.D.*).—The SPIKED CORYLOPSIS, with yellowish flowers in February. Height, 15 ft.

Cotoneaster microphylla[1] (*H.E.*).—The SMALL-LEAVED ROCK SPRAY, with white flowers in June. Height, 10 ft.

Crataegus Pyracantha (*H.D.*).—The FIRE THORN, with scarlet berries in autumn. Height, 10 ft.

Cucumis. See articles on *CUCURBITA* and *PUMPKINS AND GOURDS*.

Cucurbita.—See separate article and article on *PUMPKINS AND GOURDS*.

---

[1] For other species see article on *SHRUBS*.—EDITOR.

Cydonia japonica[1] (Syn. *Pyrus japonica*, *H.D.*).—The JAPANESE QUINCE, with white to deep coloured flowers in April. Height, 8 ft.

Desfontainea spinosa (*H.E.*).—The SCARLET HOLLY, with scarlet and yellow flowers from June to August. Height, 6 ft.

Desmodium penduliflorum.—See *Lespedeza Sieboldi*.

Eccremocarpus scaber (Syn. *Calampelis scaber*, *H.A.*, or *H.H.D.*).—Orange-red flowers in summer. Height, 12 ft.

Elaeagnus pungens (*H.E.*).—The OLEASTER, NATSU, or NOTEN GUMI, mainly grown for its foliage, some variegated forms being pretty. Height, 6 ft. (See also article on *SHRUBS*.)

Embothrium coccineum (*H.H.E.*).—The FIRE BUSH, with scarlet flowers from April. Height, 5 ft.

Enkianthus japonicus[1] (*H.D.*).—White flowers in February. Height, 9 ft.

Ercilla volubilis (Syns. *E. spicata* and *Bridgesia spicata*, *H.E.*).—The CLIMBING ERCILLA, with purple flowers in June. Height, 10 ft.

Eucryphia cordifolia (*H.E.*).—The HEART-LEAVED EUCRYPHIA, with white flowers in August. Height, 15 ft.

E. pinnatifolia (*H.E.*).—White flowers in August. Height, 20 ft.

Euonymus americanus (*H.D.*).—The AMERICAN SPINDLE TREE, BURNING BUSH, or STRAWBERRY BUSH, with pretty foliage and crimson capsules in July. Height, 16 ft.

E. americanus angustifolius (*H.D.*).—The NARROW-LEAVED SPINDLE TREE, with pretty foliage and red capsules in autumn. Height, 15 ft.

E. europaeus (*H.D.*).—The SPINDLE TREE, with white flowers in June. Height, 15 ft.

E. japonicus (*H.E.*).—The JAPAN SPINDLE TREE, with ornamental leaves, some variegated forms being popular. Height, 6 ft.

Forsythia intermedia (*H.D.*).—The GOLDEN BELL, with yellow flowers in March. Height, 8 ft.

F. suspensa (*H.D.*).—The DROOPING GOLDEN BELL, with yellow flowers in March. Height, 8 ft. Its variety *Fortunei* should also be grown.

F. viridissima (*H.D.*).—Greenish-yellow flowers in March. Height, 8 ft.

Fremontia californica (*H.H.D.*).—Yellow flowers in April. Height, 6 ft.

Fuchsia (*H.D.*). See separate article on *FUCHSIA*.

Garrya elliptica (*H.E.*).—The well-known GARRYA, with greenish-white or yellow flowers in March. Height, 8 ft.

Hedera Helix (*H.E.*).—The well-known ENGLISH IVY, useful as a climber or covering plant. The best varieties are *algeriensis*, *amurensis angularis*, *atropurpurea*, *caenwoodiana*, *canariensis* (this is the IRISH IVY), *cinerea*, *conglomerata* (only suitable for very low walls), *dentata*, *digitata*, *rhombea*, *roegneriana*, and *sagittaefolia*. Variegated forms of most of these and numerous other varieties are described in trade lists, to which readers are referred.

Humulus Lupulus (*H.D.*).—The COMMON HOP. See article on *HUMULUS*. Height, 10 ft.

Hydrangea petiolaris (*H.D.*).—White flowers in April. Height, 20 ft.

Ipomoea Bona-nox (*H.H.A.*).—The MOON FLOWER, with white flowers from June to August. Height, 12 ft.

I. hederacea (*H.H.A.*).—The IVY-

[1] For other species see article on *SHRUBS*.—EDITOR.

LIKE MORNING GLORY, with blue and other coloured flowers from June to August. Height, 10 ft.

I. purpurea (Syn. *Convolvulus major,H.A.*).—The MORNING GLORY, with white to purple-coloured flowers from July onwards. Height, 10 ft.

I. quamoclit (*H.H.A.*). — The CYPRESS VINE, with various coloured flowers from July. Height, 10 ft.

Jasminum nudiflorum (*H.D.*).—The WINTER JASMINE, with yellow flowers in February and spring. Height, 10 ft.

J. officinale (*H.D.*).—The well-known JESSAMINE, with white flowers in June. Height, 10 ft.

J. revolutum (*H.E.*).— Yellow flowers in May. Height, 10 ft.

Kerria japonica (Syn. *Corchorus japonicus, H.D.*).—Yellow flowers in March. Height, 10 ft. Its variety *flore pleno* has double yellow flowers, but is otherwise similar.

Lathyrus grandiflorus (*H.D.*).—The LARGE-FLOWERED EVERLASTING PEA, with flowers of purple and other shades in June and August. Height, 8 ft.

L. latifolius (*H.D.*).—The BROAD-LEAVED or COMMON EVERLASTING PEA, with rose to white flowers in July. Height, 8 ft.

L. odoratus (*H.A.*).—The SWEET PEA, with flowers of many colours throughout the summer. Height, 10 ft. (See separate article on *SWEET PEAS*.)

Lespedeza Sieboldi (Syn. *Desmodium penduliflorum, H.H.D.*). — Red-purple flowers in July. Height, 8 ft.

Lonicera etrusca (*H.D.*). — The ETRUSCAN HONEYSUCKLE, with purple and yellow flowers from June to August. Height, 10 ft.

L. japonica (Syn. *L. halleana, H.D.*).—The JAPAN HONEYSUCKLE, with white flowers changing to yellow in June and July. Height, 10 ft. Its variety *aureo-reticulata* has variegated leaves, while *L. j. flexuosa* has purplish-yellow flowers, but is otherwise similar.

L. Periclymenum (*H.D.*). — The HONEYSUCKLE or WOODBINE, with red and yellow flowers in July. Height, 10 ft. The late Dutch variety blooms in autumn. Height, 15 ft.

L. Standishii (*H.D.*).—STANDISH'S HONEYSUCKLE, with fragrant white flowers in January and February. Height, 5 ft.

Lycium barbarum (*H.D.*).—The BOX THORN, with purple or violet flowers in May and June. Height, 12 ft.

Magnolia conspicua (*H.D.*).—The SHOWY LILY TREE or YULAN, with white flowers in April or May. Height, 20 ft.

M. grandiflora (*H.E.*).—The BULL BAY or LARGE-FLOWERED LILY TREE, with white flowers from June to July. Height, 30 ft.

M. tripetala (*H.D.*).—The UMBRELLA TREE or ELK-WOOD, with white flowers from June to July. Height, 30 ft.

Maurandya barclayana (*H.H.D.*). —Purple flowers from July to September. Height, 10 ft.

Menispermum canadense (*H.D.*).—The CANADA MOONSEED or MOONSEED, with greenish-white flowers in June and July. Height, 6–12 ft.

Mitraria coccinea (*H.H.E.*).—The MITRE FLOWER, with scarlet flowers in June and July. Height, 5 ft.

Muehlenbeckia complexa (*H.E.*).—The EMBRACING MUEHLENBECKIA, grown for its pleasing foliage. Height, 8 ft.

Mutisia decurrens (*H.D.*).—The RUNNING MUTISIA, with orange flowers in July. Height, 10 ft.

Myrtus Luma (*H.E.*). — White flowers from June to August. Height, 9 ft.

Olearia Haastii (*H.E.*).—HAAST'S

DAISY BUSH, with white flowers in August. Height, 8 ft.

O. stellulata (*H.H.E.*). — The STARRY DAISY BUSH, with white flowers in August. Height, 4–6 ft.

Osmanthus Aquifolium (*H.E.*).— The HOLLY-LEAVED OSMANTHUS, with white flowers in August. Height, 4-6 ft.

Ozothamnus rosmarinifolius (*H.H. D.*). — White flowers from May onwards. Height, 8 ft.

Passiflora coerulea (*H.H.D.*).—The PASSION FLOWER, with blue flowers from June to August. Height, 30 ft.

P. coerulea Constance Elliot (*H.H. D.*).—The WHITE PASSION FLOWER, with white flowers from June to August. Height, 30 ft.

Periploca graeca (*H.D.*).—The SILK VINE, with brownish-red flowers in June. Height, 10 ft.

Philadelphus (*H.D.*).—The well-known MOCK ORANGE. See nurserymen's catalogues for countless species and varieties.

Pittosporum Tobira (*H.E.*). — White flowers in March. Height, 12 ft.

Polygonum baldschuanicum (*H.D.*). —Rose flowers in August and September. Height, 20 ft.

P. multiflorum (*H.D.*). — White flowers in August and September. Height, 20 ft.

Punica granatum (*H.D.*).—The POMEGRANATE, with red flowers from June to September. Height, 15–30 ft.

Raphiolepis japonica (Syn. *R. ovata, H.E.*).—White flowers in June. Height. 20 ft.

Ribes speciosum (Syn. *R. fuchsioides, H.E.*). — The CALIFORNIAN FUCHSIA CURRANT, with deep red flowers in June. Height, 8 ft.

Rosa.—See separate articles on *ROSES FOR ALL PURPOSES*, etc.

Rubus fruticosus fl. pl. (*H.D.*).— The DOUBLE BRAMBLE, with white or pink flowers in July. Height, 12 ft.

Schizophragma hydrangeoides (*H.D.*). — The CLIMBING HYDRANGEA, with white or rose flowers in August. Height, 20 ft.

Smilax aspera (*H.E.*). — The PRICKLY IVY or ROUGH BINDWEED, with pleasing foliage but insignificant flowers. Height, 5 ft.

Solanum crispum (*H.D.*).—The POTATO TREE, with blue-purple flowers from July. Height, 15 ft.

S. jasminoides (*H.D.*). — The JESSAMINE POTATO TREE, with white flowers from July onwards. Height, 12 ft.

Stauntonia latifolia (*H.E.*). — Fragrant greenish-yellow flowers in April. Height, 9 ft.

Stuartia pentagyna (Syn. *Malachodendron ovatum, H.D.*).—The best known STUARTIA, with white flowers in May. Height, 10 ft.

Tecoma grandiflora (*H.D.*).—The LARGE TRUMPET FLOWER, with orange-scarlet flowers from June to August. Height, 20 ft.

T. radicans (Syn. *Bignonia radicans H.D.*). — The TRUMPET FLOWER, with scarlet and orange flowers from June to August. Height, 30 ft.

Thunbergia alata (*H.H.A.*).—The CLIMBING THUNBERGIA, with various flowers from June to August. Height, 6 ft.

Tropaeolum aduncum (Syn. *T. peregrinum, H.H.A.*). — The well-known CANARY CREEPER, with yellow flowers throughout the summer. Height, 10 ft.

T. lobbianum (*H.H.A.*).—LOBB'S NASTURTIUM, with cream to crimson coloured flowers from June onwards. Height, 10 ft.

T. majus (*H.A.*). — The well-known CLIMBING NASTURTIUM, with various coloured flowers from June to October. Height, 12 ft.

T. polyphyllum (*H.D.*).—Yellow flowers in June. A trailing plant. Height, 3–4 ft.

T. speciosum (*H.H.E.*). — The

favourite FLAME FLOWER or FLAME NASTURTIUM, with scarlet flowers from June onwards. Height, 6–10 ft.

Vitis (VINE). — The following plants (selected from many species) are grown for their highly ornamental foliage, which generally colours beautifully in the autumn. *V. heterophylla*, however, is prized for its bunches of blue fruits speckled with black in autumn. These Vines have inconspicuous flowers, and unless otherwise indicated are Hardy Deciduous Climbers. The heights given are only approximate. For edible fruiting sorts see article on *VINE*.

V. armata.—This is a handsome sort with large leaves, which assume a fine colour in autumn. The variety *Veitchii* which must not be confused with *Ampelopsis Veitchii* of gardens, for which see *Vitis inconstans*, is especially fine. Height about 20 ft.

V. capreolata (Syn. *Vitis hederacea*).—This is a good climbing vine with pretty five-foliate leaves. It has small black fruit about the size of a currant. Height, 20 ft.

V. Coignetiae (Syn. *V. congesta*).—This is of high ornamental value both in summer and autumn. It has large leaves of beautiful form and colour. Height, 30 ft. or more.

V. congesta.—Syn. *V. Coignetiae*, which see.

V. davidiana.—Syn. *V. heterophylla*, which see.

V. ficifolia Sieboldii.—Syn. *V. Thunbergii*, which see.

V. hederacea.—Syn. *V. capreolata*, which see.

V. henryana.—This is one of the newer ornamental vines. It has deep green velvety leaves with a white mid-rib, and the latter shows well against the crimson colouring of the rest of the leaf in autumn. Height, 20 ft.

V. heterophylla (Syns. *Ampelopsis aconitifolia, A. heterophylla, Vitis davidiana*, and *V. elegans*).—This is a vigorous climbing plant with palmately lobed leaves and inedible violet fruit. The variety *dissecta* has finely divided leaves. The form called *humulifolia*, known as the TURQUOISE BERRIED VINE, has handsome leaves and pale china blue fruit. The variety *variegata* has pretty variegated leaves. Height, 10–20 ft.

V. inconstans (Syns. *Ampelopsis tricuspidata, A. Veitchii, Vitis Roylei*, and *V. Veitchii*).—This is VEITCH'S VIRGINIA CREEPER, a rapid growing hardy climber of much beauty which assumes a brilliant colour in the autumn. The variety *Lowii* has small leaves and is a good coloured one. Height, 30 ft.

V. Labrusca.—The FOX GRAPE, NORTHERN FOX GRAPE, or SKUNK GRAPE, a rapid-growing hardy Vine with rounded cordate leaves and large dark purple or amber-coloured fruit. Height, 12 ft.

V. leeoides.—This is a fine Vine with leaves which are glossy green above and deep claret underneath. Height, 12 ft.

V. megalophylla.—A plant with very large leaves which are deep green on the upper and light glaucous green on the under surface. Height, 12 ft.

V. orientalis (Syn. *Ampelopsis orientalis*).—This has fine triangular leaves of much charm. Height, 18 ft.

V. quinquefolia (Syns. *Ampelopsis hederacea, A. quinquefolia*).—This, the well-known VIRGINIA CREEPER, is a non-clinging creeper, whose pretty leaves are so finely tinted in autumn. The variety *hirsuta* (Syn. *Ampelopsis hirsuta*) has rather hairy leaves, and the variety *major* has larger foliage. Height, 30 ft.

V. Roylei.—Syn. *V. inconstans*, which see.

V. Sieboldii.—Syn. *V. Thunbergii*, which see.

V. striata (Syn. *Ampelopsis sempervirens, H.E.*).—This is sometimes sold as the EVERGREEN VIRGINIA CREEPER, but it is not nearly such a good plant in any respect as *V. quinquefolia*, especially as regards autumn colouring. Height, 15 ft.

V. Thomsonii.—This is a lovely climbing plant with highly ornamental leaves tinged with purple. Height, 20 ft.

V. Thunbergii (Syns. *V. ficifolia* and *V. ficifolia Sieboldii*).—This has larger leaves than *V. Coignetiae*. The foliage is exceedingly beautiful at all seasons. Height, 30 ft.

V. Veitchii.—Syn. *V. inconstans*, which see.

V. vinifera purpurea.—This, the TEINTURIER GRAPE, a variety of the common Vine is mentioned because of the beautiful purple colouring of the foliage. Height, 20–30 ft.

V. vulpina (Syn. *V. rotundifolia*).—This, the FROST or RIVERBANK GRAPE, has small rounded leaves glossy above and below. It has musky purplish fruit about ½ in. in diameter and without bloom. Height, 18 ft.

Wistaria chinensis (Syn. *Glycine chinensis, H.D.*).—The CHINESE WISTARIA, with purple or white flowers from May onwards. Height, 20 ft.

W. frutescens (Syn. *Glycine frutescens, H.D.*).—The SHRUBBY WISTARIA, with purple flowers in July. Height, 10 ft.

W. japonica (Syn. *Milletia japonica, H.D.*).—The JAPANESE WISTARIA, with white flowers from June to August. Height, 10 ft.

W. multijuga (Syn. *W. grandiflora, H.D.*).—The LARGE-FLOWERED WISTARIA, with purple flowers from June to September. Height, 20 ft.

S. A.

CLIMBING ROSES.—See *ROSES FOR ALL PURPOSES*.

CLIMBING THUNBERGIA (*Thunbergia alata*).—See *CLIMBING AND TRAILING PLANTS*.

CLINOPODIUM.—Now included in the genus *CALAMINTHA*.

CLISSIOCAMPA.—See LACKEY MOTH in *INSECT PESTS*.

CLIVIA (Syn. *Imantophyllum*. Nat. Ord. Amaryllidaceæ).—This is an ornamental foliage plant with glossy green leaves, bearing beautiful trusses of flowers in varying shades of orange-scarlet, and is also a most useful plant for the decoration of the conservatory and for the dwelling-house during the spring months. It is increased by division of the suckers on the old plant and by seeds, which latter should be sown as soon as ripe. Keep it moderately dry in winter. Pot in rich loam and sand. Temperature required in winter 40–45° F.

Greenhouse Species and Varieties.—*Clivia citrina.*—Yellow. Flowers from March to April. Height, 1–2 ft.

C. miniata Favourite.—Orange yellow. Flowers in March. Height, 1–2 ft.

C. m. Olympia.—Orange scarlet. Flowers in March. Height, 1–2 ft.

C. m. Optima.—Bright orange scarlet. Flowers in March. Height, 1–2 ft.

C. m. splendens.—Dark orange. Flowers in March. Height, 1–2 ft.

C. m. superbum.—Bright orange. Flowers in March. Height, 1–2 ft.

CLOT BUR.—See *XANTHIUM.*

CLOTHING TREE STUMPS.—See *TREE STUMPS : CLOTHING.*

CLOUD GRASS (*Agrostis nebulosa*).—See *ORNAMENTAL GRASSES.* The name is also applied to the genus *AGROSTIS.*

CLOVER.—See *TRIFOLIUM.*

CLOVES.—A name applied to the bulbs or sets of GARLIC and SHALLOTS which are used for planting.

CLUB-ROOT, or CLUBROOT.—See *DISEASES OF PLANTS* and *GREENS : WINTER AND SUMMER.*

CLUB RUSH.—See *SCIRPUS.*

CLUSTER CUP FUNGI.—See *DISEASES OF PLANTS.*

CLUSTER PINE (*Pinus Pinaster*).—See *TREES.*

CLUSTER PINK (*Dianthus capitatus*). See *DIANTHUS.*

CNICUS (HORSE THISTLE. Nat. Ord. Compositæ).—This genus, now including the old genus *Cirsium* (of which *C. arvense* is the troublesome CREEPING THISTLE described in our article on *WEEDS*), contains many undesirable weedy plants of no garden value whatever. One sort only is suitable for the wild garden, namely, *C. Casabonae*, the FISHBONE THISTLE. It is a hardy biennial bearing purplish-blue flowers from June to August and growing about 1 yd. high. The most notable of the weedy sorts are *C. arvensis*, the CORN THISTLE; *C. heterophyllus*, the MELANCHOLY THISTLE; and *C. lanceolatus*, the BURR THISTLE.

CNIDIUM.—Now included in the genus *LIGUSTICUM.*

COBÆA (Nat. Ord. Polemoniaceæ). This is an evergreen climber which will grow freely on poles or rafters inside the roof of a greenhouse or conservatory. It thrives in a compost of light loam, peat, and sand, and is propagated by cuttings of firm side-shoots in summer in slight bottom heat, and also by seeds. Temperature needed 40–50° F.

Greenhouse Species. — *Cobæa scandens.* — Purple. Flowers from July to September. Height, 4–20 ft.

C. s. variegata.—Variegated foliage. Flowers light purple, from July to September. Height, 4–10 ft.

See also *CLIMBING AND TRAILING PLANTS.*

COCK'S-COMB GRASS (*Cynosurus echinatus*).—See *CYNOSURUS.*

COCK'S-FOOT GRASS.—See *DACTYLIS*

COCKCHAFER GRUBS.—See under CHAFERS in *INSECT PESTS.*

COCKSCOMB (*Celosia cristata*. Nat. Ord. Amarantaceæ).—This is a greenhouse annual averaging 10–30 ins. in height, and requires a very rich soil to bring out its full beauty. Propagation is best effected by seed.

Culture.—If a warm house is available, seed may be sown in February or March, but if a hot-bed is used for germinating the seed, the latter part of April is a better time. A light rich soil should be used for the seedlings, and growth must be fairly rapid to prevent a check. A suitable compost for

potting the young flowering plants in is sandy loam two parts, and one part each of leaf-mould and old hotbed manure. As soon as the "Combs" have formed, the most promising plants should be shifted into 7-inch pots, using very rich soil; and when they are thoroughly established, give occasional doses of weak soot water till the colour begins to show on the flowers, after which plain water only is required.

USES.—If grown for bedding purposes, for which they are striking subjects, the plants must be well hardened off before placing in their flowering quarters in June. The most perfect blooms, however, are produced under glass, and they are ideal greenhouse or conservatory plants. The flowering season is throughout late summer and autumn.

Varieties.—The old dark red Cockscomb is practically the only one in the market, though *C. cristata variegata* has prettily variegated leaves.—J. L. G.

COCKSPUR THORN (*Crataegus Crus-galli*).—See *TREES*.

COCOANUT.—See *NUT CULTURE*.

COCOANUT FIBRE.

This is an exceedingly useful material to the gardener, as it is clean to handle and in every way free from objectionable properties. Bulbs may be grown in bowls of it with great success. Pot plants may be plunged in it either outside or in frames, and it can be used as a mulch for certain subjects where the use of rich material would be objectionable. Gardeners should always have a good supply of it handy for use when required.

COCOS.—For best species see *PALMS*.

CODLING MOTH.—See *INSECT PESTS*.

CODLINS AND CREAM (*Epilobium hirsutum*).—See *EPILOBIUM*.

CODONOPRASUM.—Now included in the genus *ALLIUM*.

CŒLIA.—See *ORCHIDS*.

CŒLOGYNE.—See *ORCHIDS*.

COIX (Nat. Ord. Gramineæ).

This is a genus of half-hardy perennial grasses. The best species is *C. Lacryma-Jobi*, the popular JOB'S TEARS, described under the former name in our article on *ORNAMENTAL GRASSES*.

COLAX.—See *ORCHIDS*.

COLCHICUM (MEADOW SAFFRON. Nat. Ord. Liliaceæ).—This is a genus of hardy herbaceous plants with bulbous roots. It is quite distinct from the garden *CROCUS*, on which a separate article appears, although often confused with it, as one of its species (*C. autumnale*) is popularly known as AUTUMN CROCUS, while a true member of the Crocus genus (*C. sativus*) is conversely known as the SAFFRON CROCUS. Both these plants are dealt with under CROCUS in our article on *MEDICINAL HERBS*. There are hosts of other species and synonyms, but none of them are of any great importance, so are not named here. They are all very poisonous plants.

NEW VARIETY.

Colchicum illgricum superbum.—This has rosy-purple flowers with a white base. Its tube is 3–4 ins. long.

See also under CROCUS, AUTUMN, in *MEDICINAL HERBS*.

COLD FRAME or PIT.—See *GARDEN FRAMES*.

COLD GREENHOUSE.—See *GREENHOUSE: COLD AND UNHEATED*.

COLEUS (Nat. Ord. Labiatæ).—This is an evergreen shrub of easy culture. Amongst the hybrids many fine kinds with distinct foliage can be obtained by seed the first season. Cuttings may be struck in heat in spring. The soil should be of loam, peat, and sand. Temperature required 50–55° F.

Greenhouse Species.—*Coleus thyrsoideus.*—An exceedingly handsome plant. The branches terminate in erect panicle-like racemes of ten to fifteen bright blue flowers, with a spike over a foot in length. The flowering period is from November to February, and the height of the plant ranges from 1½–3 ft.

COLEWORT (*Brassica oleracea.* Nat. Ord. Cruciferæ).—These are popularly known as BUNCH GREENS, thousands of them finding their way to our large markets each year; the tenderness of the young leaves coupled with their sugary flavour, making them acceptable at tables where the more popular large growing varieties of cabbage would not find favour.

Culture.—To supply heads for early autumn use, seed should be sown as early in April as the state of the soil allows, other sowings being made a month later to carry on the supply throughout the winter.

It is important the seed be sown on a rich, and firmly-trodden bed. Sow thinly in drills 6 ins. apart; this is preferable to the more common plan of sowing broadcast. The seedlings should be transferred to permanent quarters when about 6 ins. high, a foot each way being ample for the development of the small heads.

Like all members of the Brassica tribe, these thoroughly appreciate a rich root run, and where this is not provided, the growth will be slow, and the table quality when cooked sadly inferior to Coleworts given a more generous diet. Plenty of moisture at the root should be given until the plants have taken well hold of the soil, after which the hoe should be freely used between the rows. An occasional watering with liquid manure, or a light sprinkle of Nitrate of Soda, given between the plants and well stirred into the soil with the hoe will assist them greatly.

The most useful variety is that known as *Rosette,* which forms a fair-sized compact growing head. every leaf of which has some culinary value.—F. R. C.

COLLEGE COURSE.—see *GARDENERS.*

COLLERETTE DAHLIAS.—See *DAHLIA: CULTURE OF.*

COLLETIA.—For the best species see *SHRUBS.*

COLLIER.—See under BEAN APHIS in *INSECT PESTS.*

COLLINSIA (Nat. Ord. Scrophulariaceæ).—This is a family of useful hardy annuals which are of branching habit and bear small Snapdragon-like flowers, mostly disposed in tiers along the growth. They are easily raised from seeds sown in March or April, or in the autumn in a sheltered position. In the first case the plants should be thinned out to 6 ins. apart each way; in the latter they must be transplanted to that distance in the early spring. We describe the best species below:—

Collinsia bartsiaefolia (Syn. *C. hirsuta*).—There are white and purple varieties of this summer flowering sort, both of which grow to 1 ft. high.

C. bicolor (Syn. *C. heterophylla*).—This is a useful town plant suitable for groups in flower borders. It bears white or lilac flowers throughout the summer, and grows 1½ ft. high. The variety *candidissima* is pure white.

C. corymbosa.—This bears white and grey-blue flowers throughout the summer. It is of branching habit, and grows 9 ins. high.

C. grandiflora.—This is a purplish-blue summer flowering sort which grows about 1 ft. high.

C. tinctoria (Syn. *C. septemnervis*).—This pink summer flowering sort grows 1 ft. high.

C. tricolor.—Syn. *C. verna*, which see.

C. verna (Syn. *C. tricolor*).—This is a purple and blue summer flowering sort which grows 1 ft. high.

COLLINSONIA (Nat. Ord. Labiatæ). This genus is not at all largely grown, but it may well be included in the hardy herbaceous border where the collection is somewhat extensive. It is of easy culture, thriving in any ordinary soil in moderately damp spots, and is not hard to increase by division of the roots in February or March, at which time it may suitably be planted.

What to Grow.—Room need not be found for more than one or two of the following three species :—

Collinsonia anisata.—A yellow October flowering sort averaging 1 yd. in height.

C. canadensis.—Probably the most popular sort. All the varieties of this bear yellowish or pale purple blooms in September or October, and average about 1 yd. in height.

C. scabriuscula (Syn. *C. tuberosa*).—A yellowish sort flowering rather earlier than either of the above, coming out as it does in August. It is not so tall either, averaging rather less than 2½ ft. in height.

COLLOMIA (Nat. Ord. Polemoniaceæ).—Most of the species of Collomia known in gardens are hardy annuals readily raised from seeds sown either in the spring or autumn. So far they have not attained to any large measure of popularity, but the bright flowers are attractive, and the genus seems to warrant the attention of raisers. The following species love sunshine and flower most freely if grown in rather poor soil :—

Collomia coccinea (Syn. *C. lateritia*).—This is the best of the cultivated annual species. It produces bright scarlet flowers throughout the summer, and averages 1½ ft. high.

C. gilioides (Syn. *C. glutinosa*).—This red or pink sort blooms freely in the autumn, and averages 1½ ft. high.

C. grandiflora.—This red or pink sort flowers in July and August, and grows 2 ft. high.

C. heterophylla.—This produces purple flowers throughout the summer, and rarely exceeds 1½ ft. high.

C. linearis (Syn. *C. tinctoria*).—This red or yellow-brown sort flowers in the early summer, and grows about 1 ft. high.

COLORADO BEETLE.—See *INSECT PESTS*.

COLORADO WHITE FIR (*Abies concolor*).—See *TREES*.

COLOUR BEDS.—See *COLOUR GARDENING : SINGLE COLOUR BEDS*.

COLOUR GARDENING : COLOUR SCHEMES.—Colour gardening is not just a luxurious phase of horticulture, but something which plays an essential part, if one is to see the various brilliant flowering subjects employed in a perfectly natural setting,—a fact which gives the owner of a small garden just as much scope as the possessors of spacious grounds. Our first examples of colour gardening will, therefore, be devoted to the smaller beds and borders, as being likely to appeal to the greater number, and happily there are many charming combinations possible even on this restricted scale.

In a border from 15–20 yards in length, no attempt should be made to display many colours ; a finer effect is possible by relying on blue, salmon, and white.

Pillars of Roses such as *Lady*

Godiva (salmon-pink) and *White Dorothy* are very effective as a background in such a border, whilst the best flowering subjects in blue, salmon, and white for the height of summer would include blue Anchusas, and blue Delphiniums such as *Mark Twain* and *Charles Reade*, salmon Phloxes such as *Elizabeth Campbell*, *Fort de France*, and *Sheriff Ivory*, the perennial *Chrysanthemum maximum* (*King Edward VII*) and the beautiful Madonna Lily supplying the white.

Along the front of the border patches of the charming salmon-pink *Carnation Raby Castle* may be used, towards the back the stately *Campanula pyramidalis* in blue or white, or in the back rows, clumps of Sweet Peas in the requisite shades. Spring effects in the same colours may be obtained by edging with white Arabis and blue Chionodoxas, whilst salmon may be introduced by making use of imposing clumps of Darwin Tulips, *Duchess of Westminster* and *Salmon King*. Autumn colouring in the same shades is possible if Border Chrysanthemums such as *Débutante*, *Framfield's Early White*, and *Tapis de Neige* (all white), are used; while blue will be represented by the second blooming of the Anchusas and Asters, *Blue Bird* and *Feltham Blue*; salmon by the use of Dahlias approaching that shade, and the last blooms of *Lady Godiva Rose*.

Another very pretty soft effect may be obtained by the massing of white, mauve, and lavender. There are many subjects from which one might make a choice to carry out a scheme of this kind, but it should be mentioned that Michaelmas Daisies grouped in these colours only, make a glorious autumn display. One more example will suffice for demonstrating the possibilities of colour-blending on a small scale, and this concerns a wonderfully pretty effect obtained by the writer, by simply dotting a large bed with vermilion autumn-flowering Tritomas, surrounding them with white *Southcote Beauty Aster*.

Broad Borders. — Briefly, the effect to be aimed at here should be one of real harmony in the relationship of the various brilliant subjects used, rather than violent contrasts.

Each colour must be massed in strength enough to be impressive, without being so dominant as to become obtrusive; let the effects obtained be natural. The planter should avoid trying to improve upon Nature's colouring, but must rather aim at placing every colour in a natural setting.

In planting for a colour progression remember that the plants bloom in varied seasons. This makes it imperative to use the various subjects with a view to keeping up a long succession in the desired colours. For example the Doronicums, the earliest golden-yellow flowers to bloom, must be placed in close proximity to the Helianthuses, the last to bloom in the same hue.

Colour Progression. — By this is meant that, looking at the border from either end, the colours should all blend, so that each plant enhances its neighbour's beauty. To obtain this effect begin with white flowers, intermingled with silvery-grey foliage plants. Next to this pink and rose-shades might be placed, followed with light blue, and working on into the strongest shades of that colour.

Blue associates charmingly with yellow, so place this colour next, leaving warmer tones such as crimson, red, and scarlet an honoured place in the centre of the

whole arrangement. If a foil of white is objected to, between orange and crimson, carefully grade all these warm tones from red to orange. After thus disposing of the reds, follow on with a batch of pale yellow, and finish up with lilac and purple shades, which form a really charming combination.

Bearing this in mind, other salient points to observe are that the principal value of white flowers lies in the fact of their use as a foil between bright and varying hues. Employed thus they lose much of their natural coldness, but at the same time it is well to avoid the repetition of white patches along the length of the border, otherwise it might prove tiring to the every-day observer.

Pink and rose shades are entrancing with yellow and blue, whilst silvery-grey foliage plants are invaluable as a set-off, if used beneath taller-growing, brightly coloured flowers.

Background and foreground both play their part in a colour border, and in connection with the latter point, avoid all formal edging, having (if a grass verge is not possible) a low-stone edging, because this makes it possible to plant alpine subjects of a spring-flowering character. As far as background is concerned, some hold that none is required beyond that provided by the tall-growing subjects in the back rows. That may be. If the colour gardener has to plant against a wall, old stone is preferable to bricks. If climbers are introduced, avoid subjects which would clash with occupants of the border; patronise Ceanothuses, Clematises, Climbing Roses, and Wistarias in the colour required.

Where there is no wall, pillars of Roses and clumps of Sweet Peas would not only form an effective background but greatly assist in the general colour scheme.

A selection of plants to carry out the colour progression advocated is here appended, and if some well-known kinds are absent, it is because the writer contends that in planting for colour effect, the subjects selected must be vigorous in growth, as well as effective in blooming.

SOME SUITABLE SELECTIONS.

Blues (Pale and Dark).

First Row (*i.e.* Back Row).—Asters Blue Bird, Climax, and Feltham Blue; Delphiniums Capri, Geneva, Jupiter, King of Delphiniums, and Orion; Echinops Ritro; Galega Hartlandi; Sweet Peas Captain of the Blues, Lord Nelson, Royal Blue, and Southcote Beauty.

Second Row.—Aconitum Wilsoni; Aster cordifolius, Aldeboran, and Paragon; Campanula pyramidalis; Delphinium Geneva; Salvia nemerosa virgata.

Third Row.—Aconitum Fischeri; Aster Amellus, Bedding Queen, Emma Bedau, Onward, and Orion; Campanulas latifolia and macrantha; Clematis Davidiana.

Fourth Row.—Anchusa italica, Dropmore Variety and Opal; Erigeron The Quakeress; Phlox Le Mahdi, and Ouragan; Scabiosa caucasica.

Fifth Row.—Campanula persicifolia; Iris germanica, Clio, Maritana, Mrs Kessler, and Nationale; Linum narbonense; Verbena venosa; Veronica spicata.

For Stone Edging.—Anchusa Myosotidiflora; Aubrietias Dr Mules, Perry's Blue, and Prichard's A1; Campanula Riverslea; Linum alpinum; Nepeta Mussini; Phlox G. F. Wilson; and Veronica prostrata.

Crimson, Red, and Scarlet.

First Row (*i.e.* Back Row).—Aster Novae-Angliae, Mrs J. F. Rayner; Dahlias Charles Ducrot, Dormouse, John Riding, and Meteor; Eupatorium purpureum; Hollyhock Crimson King; Rose (for pillar) Hiawatha; Sweet Peas Edward Cowdy, Maud Holmes, and Sunproof Crimson.

Second Row.—Dictamnus Fraxinella; Kniphofias Saundersi and Cloto; Lychnis chalcedonica; Lilium chalcedonicum; Malope grandiflora; Monarda didyma.

Third Row.—Anemone japonica Prinz Heinrich; Antirrhinums (tall), Deep Crimson and Fiery Belt; Delphinium cardinale; Paeonies Henri Demay and Louis Van Houttie; Phloxes George A. Strohlein and Thomas Swanston.

Fourth Row.—Lobelia cardinalis; Papaver Beauty of Livermere; Pentstemons Ariel, Damocles, Ethel Howe, and Newbury Gem; Potentillas Flambeau and Le Vesuve; Pyrethrums Captain Nares and Lord Rosebery.

Fifth Row.—Chrysanthemums Crimson Pride and Goacher's Crimson; Delphinium nudicaule; Gladiolus Brenchlyensis; Heuchera brizoides; and Primula japonica.

For Stone Edging.—Helianthemums Red Dragon and venustum plenum; Saxifrages Ditton Crimson, Mrs D. Hudson, and Ware's Crimson.

Pink and Rose.

First Row (*i.e.* Back Row).—Asters Lil Fardell and Rosy Morn; Astilbe Davidii; Hollyhock Rose Queen; Lavatera Olbia; Rose (for pillar), Blush Rambler; Sweet Peas Barbara, Doris Usher, and Queen of Pinks.

Second Row.—Asters Elsie Perry and Perry's Favourite; Astilbe Peach Blossom; Dahlia Delice; Dicentra spectabilis; Phloxes Elizabeth Campbell, La Siecle, Sheriff Ivory, and Wm. Robinson.

Third Row.—Chelone Lyoni; Clarkia Carnation Flaked; Phlox Mrs Oliver; Pyrethrum Queen Mary; and Saponaria officinalis flore pleno.

Fourth Row.—Clarkia Salmon Queen; Paeonies The Queen and Reine Elizabeth; Papaver Blush Queen; Pentstemon Pink Beauty; Pyrethrum Hamlet; and Sweet William Pink Beauty.

Fifth Row.—Antirrhinums Carmine Pink and Delicate Pink; Carnation Raby Castle; Heuchera Pink Pearl.

For Stone Edging.—Gypsophila prostrata rosea; Helianthemum Sunbury Gem; and Saxifragas umbrosa and Wenlock's Best of All.

White.

First Row (*i.e.* Back Row).—Aster Novi Belgii White Climax and White Queen; Bocconia cordata; Dahlia Queen Mary; Hollyhock White Queen; Romneya Coulteri; Sweet Peas Constance Hinton and King White.

Second Row.—Delphinium Moerheimi; Galega officinalis alba; Galtonia candicans; Lilium candidum; Phlox pyramide; and Spiraea Aruncus.

Third Row.—Campanula pyramidalis (white); Cimicifuga cordifolia; Gypsophila paniculata; Paeonies superba and Whitneyi; Phloxes Snowdon and Tapis Blanc.

Fourth Row.—Antirrhinum Pure White; Irise Bridesmaid and Innocence; Pentstemons Antarctic and Galatea; and Pyrethrum Aphrodite.

Fifth Row.—Achillea The Pearl; Anemone alpina; Stachys lanata; Trillium grandiflorum; and Veronica spicata alba.

For Stone Edging.—Arabis albida; Arenaria grandiflora; Asperula odorata; Campanula carpatica alba; Campanula pusilla alba; and Iberis sempervirens superba.

Yellow.

First Row (*i.e.* Back Row).—Dahlia Brentwood Yellow; Helianthus Miss Mellish; Hollyhock Prince of Orange; Rudbeckia Golden Glow; Solidago Golden Wings; Sweet Peas Hon. Mrs E. Kenyon and Primrose Queen; and Verbascum olympicum.

Second Row.—Alstroemeria aurantiaca; Helenium autumnale; Kniphofia Tuckii; Solidago Golden Locks; and Verbascum caledonia.

Third Row.—Anthemis tinctoria Kelwayi; Coreopsis grandiflora; Eremurus Warcii; Helenium Riverton Beauty; Kniphofia Star of Baden Baden; and Rudbeckia speciosa.

Fourth Row.—Antirrhinum Cloth of Gold; Gaillardia Lady Rolleston; Hemerocallis Lemon Queen; and Trollius Orange Globe.

Fifth Row.—Aquilegia chrysantha; Heleniums Bigelovii and Hoopesii; and Trollius grandiflorus.

For Stone Edging.—Adonis vernalis; Alyssum saxatile; Genista humifusa; and Violas Bullion and Klondyke.

NOTES.—The foregoing list contains just a few of the many good things available. The lilac, mauve, and lavender section is best represented in the Michaelmas Daisies and Flag Irises. The list has been divided into rows not for rigid planting as set out, but more as a general indication of how the plants should be graded in height from the back.

So much reference has been made to subjects with silvery-grey foliage, that an enumeration of the principal kinds is due to the reader. Amongst these are *Cerastium tomentosum* (silvery-grey foliage and white flowers), *Cineraria maritima* (silvery laciniated foliage and yellow flowers), *Geranium argenteum* (rose flowers and silver foliage), *Glaucium flavum* (silver glaucous foliage and yellow flowers), and *Thymus Serphyllum album* (white flowered and sheets of attractive foliage).

Colour Schemes with Annuals.—For obtaining brilliant colour effects it is doubtful if annuals can be surpassed when properly arranged. For example, a border composed entirely of Godetias in varying shades produces a gorgeous effect. A long border, with the variety *Apple Blossom* in the back row, *Duchess of Albany* (white) in the second row, with *Dwarf Pink* and *Afterglow* (scarlet-crimson) for the outside rows, produces a charming effect. Larkspurs also pay for attention in colour-grouping, and a bed of the variety *Rosy Scarlet*, surrounded with yellow ten-week Stocks, is very fine, especially in the soft evening light.

Antirrhinums, although not strictly annuals, are generally treated as such, and their adaptability to colour-blending is well known, their wide range of tints (or shades) giving the colour-gardener great scope.

In planting small beds, only one variety must be used; but in large circular beds, brilliant effects may be achieved by planting a crimson variety in the centre, making a belt of white and yellow around this colour, next a belt of orange, finally edging the bed with a dwarf yellow variety.

Pretty as this bed would be, it could be surpassed if a slightly-raised long border, backed with an ivy-clad wall, is available. In this event a pale yellow sort in the back rows, followed by apricot, and then a ribbon of orange, finishing with coral-red in the row next to a dwarf-yellow edging, is a revelation of the possibilities of colour combinations. Large beds on lawns can be charmingly filled if clumps of Sweet Peas in yellow and cream shades are surrounded by the tall *Antirrhinum Orange King*. Generally speaking other annuals, such as Asters, Clarkias, Cosmos, Cyanus, Nasturtiums, and Stocks, as well as Lavateras, Nemesias, and Salpiglossis, show to much better advantage when only one variety is planted in each bed.

Good edging annuals are Candytuft, Dianthus, Dimorphotheca, Linum, Mignonette, and dwarf Phlox (*i.e.* Drummondii). There is little difficulty in arranging any of these for colour effect, especially if a soft, restful setting instead of hard gravel pathways is available.

The importance of proper colour-blending in the garden, it might be said in conclusion, is not only from the purely artistic point of view, but is also health-giving, for it has been well and truly stated that few people realise the effect colour has on the course of one's life and character.—F. W. M.

COLOUR GARDENING: Single-Colour Beds.—The wealth of floral material now available facilitates the employment of pleasing one-colour schemes at, practically, all seasons, without sacrificing that variety necessary to create and sustain interest in formal flower gardening. In such schemes harmonious groundwork or tasteful edging of foliage plants, or even the more modest flowering subjects, is not only permissible but actually demanded to do justice to the *pièce de resistance*.

While the finest spring, single-colour effects are, perhaps, obtained by planting distinct varieties of Hyacinths, Early and May-flowering Tulips, and other bulbous subjects *en masse*, economy demands spacing out, which in its turn necessitates the employment of a suitable groundwork for pleasing effect. Here, the double-flowered *Arabis albida*, in quiet, grey-shaded foliage, and silvery, unobtrusive flowers, combines splendidly with most things. *Tulip Pink Beauty* on such a carpet is a revelation.

By accident, rather than design, was revealed the best spring harmony in blue probably ever obtained. This, the filling in of beds which had a permanent substantial edging of London Pride (*Saxifraga umbrosa*), with Royal Blue Forget-me-not, the flowering of the two contemporaneously producing that æsthetic shade of colour sometimes seen ascending heavenward 'twixt the trees from the wood fire of a country cottage chimney. This, amplified by cross-banding, either bed or border, right and left diagonally, resulting in diamond panels filled in with blue Forget-me-not, even goes one better in unique effect from the near distance, and although perfectly simple is simply perfect.

For warmth of spring colour tone the old form of *Silene pendula* from seed sown in August for transplanting to the beds, and bordered with pink Saponaria of the same soft hue, makes a charming *coup d'œil* in the spring garden. The free habit of the typical Silene, which results in its growing up into a glowing mass, is preferable for this purpose to its restricted variety, *S. p. compacta*. The glory of glowing colour perhaps in this direction is attained in *Saponaria Scarlet Queen*, to be similarly raised in the autumn for transplanting, although either Saponaria seems less amenable to enduring winter severity. Dean's hybrid Primroses are very beautiful for spring work, if we select from the seed-bed plants of one-colour tones, although some liberty may be allowed in the variety, which is almost infinite.

The rose garden contrived on the single-colour bed scheme, each bed being devoted to one variety, and leading in a series of colour-beds and gradations of colouring, from the pure white of *Snow Queen* (née *Frau Karl Druschki*) to a central mass of the glowing crimson *General McArthur*, makes a right royal rose garden. On the larger scale of the rose garden the planter has a wealth of material in the various sections of dwarf Polyantha, Teas, Hybrid Teas, and Hybrid Perpetuals to select from, to which the Wichuraiana may be added in judicious arrangement and disposal on pillar, arch, or series of arches to complete a scheme inherently capable of making the very apotheosis of the Rose, "the very fairest flower that blows."

Yellow Roses, with a charm peculiarly their own, well deserve a parterre to themselves, and for a dozen beds in pairs the following are admirably adapted, commencing with the lemon-yellow of *Alex. Hill Gray* (T.), and finishing with *Golden Spray*

(H.T.), the free habit of the latter commending it for the central position, the intervening varieties in order being *Duchess of Portland* (H.T.), *Golden Emblem* (H.T.), *Lady Hillingdon* (T.), and *Madame Ravary* (H.T.).

Annuals and biennials provide a maximum of interest and summer beauty at a minimum of expense. Of the latter none can excel the bright floriferousness of Antirrhinums,[1] preferably the intermediate type, in distinct colours. With these alone the whole gamut of colour can be run, and the garden made gay the season through, such being raised from seeds sown early in the spring under glass, or autumn raised plants, hardier grown, under the protection of a cold frame. Either for box-edged beds, or beds simply cut in the turf, these Snapdragons in pure white, soft lemon-yellow, peerless pink, golden chamois, or deep crimson give a range of colour which affords them high rank for our purpose. As a pure white annual, flowering the season through (provided seed-bearing on the first spikes is prohibited), the Hyacinth-flowered Candytuft is unsurpassed; its companions, *Carmine Queen*, and the older lilac-purple form, golden, crimson, and white Mignonette, if more modest in tone, are as adaptable as they are indispensable in any flower-garden scheme. For colour effect at a minimum of expense and labour, dwarf Tropaeolums (Nasturtiums) are a host in themselves as far as scarlet, maroon, terra-cotta, pale yellow, and old gold are concerned. With the latter, nevertheless, hard-tramped, poor soil is *the* flowering secret, and if seeds are dibbled into such a medium, 6 ins. apart, in April, germination is rapid, gross leafage avoided, and the effect is pretty well continuous if seeding is not allowed.

For colour comfort it is yet a question if anything can vie with the scarlet Geranium (*Pelargonium*), given such brilliant kinds as *Paul Crampel*, disposed *en masse* on a complimentary colour carpet of well-kept greensward, a silver-leaved variety being utilised as its edging. Such, indeed, is able to light up a whole landscape within eye range. Very different, but quite charming, is the old-fashioned plan of planting the pretty purple, half-hardy *Verbena venosa* on a groundwork of the equally old-fashioned *Pelargonium Manglesii*, a well-raised bed of such being peculiarly telling in its refined beauty.

Very pleasing winter effect is gained by the employment of shrubby foliage plants *en bloc*, and beds of such may well come into present consideration in any scheme of flower gardening, including the terraced garden. Distinct foliage subjects will be found in *Cassinia* (Diplopappus) *fulvida*, the quieter but not less distinct *Griselinia littoralis*, while blocks of *Mahonia* (Berberis) *Aquifolium*, annually clipped till more or less solidity results, give grand effect in red-bronze vividly renewed each spring. In conclusion, all the above, proved in practice, are but little more than suggestive of a subject practically inexhaustible.—E. K.

COLOUR SCHEMES.—See *COLOUR GARDENING: COLOUR SCHEMES.*

COLTSFOOT (*Tussilago Farfara*).—See *TUSSILAGO* and *WEEDS.*

COLUMBIAN BARRENWORT.—A name applied to *VANCOUVERIA*, which see.

COLUMBINE.—A popular name for the genus *AQUILEGIA*, which see.

[1] Antirrhinums are by many people considered as perennials. They may, however, be treated as biennials, and are largely grown as such still.—EDITOR.

COLUTEA.—For the best species see *SHRUBS*.

COMARUM.—Now included in the genus *POTENTILLA*.

COMFREY.—See *MEDICINAL HERBS* and *SYMPHYTUM*.

COMMELINA[1] (DAY FLOWER. Nat. Ord. Commelinaceæ).—One species of this, *C. communis*, is a pretty hardy annual bearing blue-purple flowers from June onwards, and growing 1–2 ft. in height. It is of the simplest culture, merely requiring to be sown where it is to grow in March or April and ruthlessly thinned out.

Perennial Border Species.—The two described below are of sterling merit, and should be planted in good rich soil in the early spring. They may be propagated by seeds or root division in the usual way.

Commelina coelestis.—This, which is not quite hardy, bears gloriously blue flowers from June onwards, and grows 1½–2 ft. in height. A white variety *alba* is also useful.

C. erecta (Syn. *C. obliqua*).—This bears lovely blue flowers from August onwards, and grows 1–2 ft. in height.

COMPASS PLANT (*Silphium laciniatum*).—See *SILPHIUM*.

COMPENSATION FOR IMPROVEMENTS: THE LAW AS TO.—See *GARDENING LAW*.

COMPOSTS.

The question of providing a suitable compost for the various plants he cultivates is often a source of much anxiety to the beginner in greenhouse gardening, and although the present race of growers are not nearly so exacting in the preparation of potting composts as those of the "old school," even to-day, when conditions are made much more favourable to plant-growth under glass than formerly, it is useless expecting the best results to follow if a plant is not given something approaching an ideal compost for the roots to feed upon. Unless this is provided, many plants, although not positively dying at once, soon become sickly, and a prey to various pests and diseases.

Without wishing to make light of what experts have written regarding the most suitable composts for various popular greenhouse plants, we may fairly claim that any one having a stack of really good fibrous loam, peat, and well-decayed leaves from Oak or Beech trees, together with some sharp silver sand and well-decayed manure, has at his disposal the material for making up a compost well suited for any plant of which he is likely to undertake the cultivation.

Good fibrous loam which has been stacked at least a year or more, should be the foundation of all composts for what are termed soft-wooded greenhouse plants, and if to this is added one-third good flaky leaf-soil, and the same of well-decayed manure, also an eighth part coarse sand, a compost capable of growing magnificent specimens of Fuchsias, Geraniums, Heliotropes, and almost all the half-hardy tender greenhouse plants or annuals will be at his disposal.

Plants of more robust growth than those mentioned, or others expected to remain in the same pot for a considerable time, may have a little of one of the advertised plant-foods added.

Azaleas, Heaths, Palms, and the majority of Ferns appreciate good fibrous peat and plenty of sand, in fact many growers add nothing else,

[1] A number of greenhouse and stove evergreens are purposely omitted from this article, the first as they are comparatively unimportant, and the second as they are beyond our present scope.—EDITOR.

but where peat is not easily obtained equal parts fibrous loam may be added.

Arums, Agapanthuses, Clivias, and similar plants having large fleshy roots, prefer a compost in which good yellow loam predominates.

Generally speaking a very rich soil is not desirable for plants having variegated or highly-coloured foliage; a poor soil being more likely to bring out the various markings than one made rich with manure.

Cucumbers and tomatoes give heavier crops when planted in turfy loam, to which not more than one-third of old manure has been added at the start; reliance being placed upon the judicious use of artificial or liquid manure to maintain these in a fruitful condition.

Old potting soil from any of the above, if put through a fine sieve, answers well for pricking out bedding plants of all kinds, while loam, leaf-soil, and sand in equal parts form a good striking compost for cuttings of the most popular greenhouse plants.

It should be noted that thorough mixing of each of the above composts is of vital importance, and a sharp lookout should be kept for harmful insects.

During the winter months the compost should be prepared, and allowed to stand in the greenhouse a few days before using, in order that it may get warmed through.

F. R. C.

COMPOUND FERTILISERS.—See *MANURES.*

COMPSOA.—Now included in the genus TRICYRTIS.

CONCRETE.—See *MORTAR.*

CONDUCTING TISSUES.—See under TISSUES in *PLANT PHYSIOLOGY.*

CONDY'S FLUID.

This is most useful as a deodoriser and disinfectant. Weak solutions, such as a dessertspoonful per gallon, have been found useful, however, for mild fungoid attacks.

CONE-FLOWER.—See *RUDBECKIA.*

CONGLOMERATES.—See under SANDSTONE in *ROCKWORK.*

CONIFER ROOT ROT.—See *DISEASES OF PLANTS.*

CONIOGRAMME.—Now included in the genus GYMNOGRAMME, for which see *FERNS AND FERN GARDENING.*

CONIOSELINUM.—Now included in the genus *LIGUSTICUM.*

CONIUM (Nat. Ord. Umbelliferæ).

This is a genus of coarse growing weedy plants of little value save in the wild garden. The best species is *C. maculatum*, better known as HEMLOCK, the culture and properties of which are fully described under that name in our article on *MEDICINAL HERBS.* It must be carefully distinguished from WATER HEMLOCK (*Cicuta virosa*), on which we give a separate note.

CONSERVATORY.

The Conservatory of whatever design, be it elaborate and costly, or plain and economical, must be so constructed that the gardener may have the opportunity of displaying his skill, and repaying his employer with a rich and varied collection of well-grown plants and flowers at all seasons of the year, so that they may at all times arouse admiration, and be enjoyed to the full, for their many forms, colours, and perfumes. The ideal structure must admit the maximum amount of light; it should have a south, south-east, or south-west aspect; and be fitted with up-to-date top and bottom ventilators; and an adequate heating arrangement that will ensure the desired temperature without in the

slightest degree overheating the pipes. Light and heat are two important factors governing the life of plants and flowers; prolonging, or shortening, as the case may be with good or bad management. The atmosphere must at all times be kept genial and buoyant by admitting the proper amount of air without causing cold draughts.

The arrangement of plants in bloom at all times must be of a light, pleasing, and decorative style, combined with a harmonious blending of colours. A conglomeration of all the plants and flowers that can be collected together, irrespective of size and colour, gives a very bad effect. The larger the group the more scope there is for an effective display.

In arranging the plants commence as high as possible and taper to the ground, with here and there the best plants standing up at varying heights to catch the eye and take away all formality of arrangement. Each plant must, however, be given ample room to show itself individually.

The combination of colours enhances or mars a group, and a medley of colours suits but few tastes. It is better usually to arrange good groups of plants of one, two, or three colours together, rather than to rely on a general mixture. Seeds of such plants as Cinerarias, Cyclamens, and Primulas can nowadays be purchased in separate colours to suit individual tastes, and this greatly assists the cultivator in making artistic displays.

What to Grow.—The selection of plants depends largely on individual tastes, but rather grow bold and impressive masses of a few kinds, than get too many on hand. Plants very showy and easily raised from seeds, are:—*Antirrhinum Nelrose*, for spring blooming; Begonias, double, single, crested, and fringed; Calceolarias, herbaceous, and *C. Clibranii*; *Campanula pyramidalis alba*, *Celosia plumosa*, Cineraria large flowered, and *C. stellata*; *Clarkia elegans Salmon Queen* and *Scarlet Gem*; Cyclamen in separate colours, and *Cyclamen Mrs. Buxton*; Gloxinias, Godetia, tall double pink, and the New Lavender variety; *Humea elegans*, Mignonette, *Primula sinensis*, in separate colours, *P. Kewensis*, *P. Malacoides*, and *P. obconica*; Schizanthus large flowered hybrids; Streptocarpus giant flowered, pink and white; Stocks, East Lothian varieties, and *Beauty of Nice*.

Bulbous Plants contribute not a little to the upkeep of the Conservatory. *Lilium longiflorum*, and its variety *Harrisii*, and *L. auratum* in variety, with the improved *L. speciosum* forms, are especially fine subjects. Nerines no doubt have a great future when the new hybrids become better known; they stand in the front rank of autumn blooming plants. *Vallota purpurea*, when grown in good batches, creates a striking display of scarlet. Hippeastrum hybrids in spring are a most gorgeous class of plants, but require heat for their growing season. *Calla aethiopica* is a bold plant, and the yellow Callas are worthy of extensive cultivation. Freesias for their graceful appearance and delicious scent must be included. Hyacinths, Narcissi, and Tulips are very cheerful early in the year when forced, and May-flowering Tulips for spring displays. Lilies of the Valley, both from retarded and natural crowns, are charming in winter and spring, the last, of course, for their pure white flowers and sweet scent.

Hard-Wooded and other serviceable flowering plants include, *Azalea indica*, in many charming shades, *Azalea mollis*, and other hardy shrubs, lists of which may be found

in autumn catalogues. Himalayan Rhododendrons, *Cytisus racemosus*, *Deutzia gracilis*, Astilbes, Hydrangeas, *Daphne indica*, and *Aloysia citriodora* are useful for their charming scents. Hybrid Clivias, *Salvia splendens*, Pelargoniums (Zonal, Show, Ivy-leaved and scented-leaved); Fuchsias and Chrysanthemums; and Begonias of the *Gloire de Lorraine* type, or the winter flowering hybrids, are most excellent Conservatory plants, but require a little more heat than ordinary greenhouse temperature.

FOLIAGE PLANTS also play an important part, and just enough greenery must be included with the flowers to give an impressive and good effect. For the most desirable species reference should be made to our article *FOLIAGE PLANTS FOR ALL PURPOSES*.

BASKET PLANTS may be freely used in the Conservatory. Ivy-leaved Pelargoniums, drooping Fuchsias, *Campanula isophylla* blue and white, Achimenes, Begonias (both the tuberous sorts and *Gloire de Lorraine* varieties), and *Asparagus Sprengeri* are all suitable. For others see our article on *BASKET PLANTS*.

CLIMBING PLANTS are numerous, but it is not at all desirable to add too many, nor is it wise to allow them to exclude much light from the roof. However, walls and pillars may be furnished with choice Tea and Hybrid Tea climbing roses, *Acacia Riceana*, *Asparagus plumosus nanus*, *Carpenteria californica*, *Clianthus puniceus*, *Lapageria rosea*, and *alba*; *Plumbago capensis*, *Rhododendron Lady Alice Fitzwilliam*, *Streptosolen Jamesonii*, and any of the half-hardy plants described in the article on *CLIMBING AND TRAILING PLANTS*.

General Management.—Cleanliness in the Conservatory is of first importance, and decaying leaves, with fading flowers, must be removed daily. Staking and tying, to keep up a well-kept appearance which assists greatly in the decorative qualities of the display, should be carefully attended to. Greenfly and Thrips very quickly damage any bloom, and must be dealt with by fumigating when first detected. See article on *FUMIGATING*. Watering, along with the cleaning, must be done in early morning, and it must be understood that plants in bloom require more water than at any other time. Plants well grown and fed for their blooming period, will need no assistance by liquid manures, during their stay in the Conservatory, therefore no disagreeable smells will arise from this source.

The lists of plants named in this article are by no means exhaustive, but simply a selection of cheery, good-natured, and showy plants. Never allow sentiment to prevail over the senses, but periodically discard old favourites, thereby making room for new and up-to-date plants, which inspire and add interest continually in the Conservatory.—D. L.

CONSTANTINOPLE HAZEL (*Corylus Colurna*).—See *TREES*.

CONSTRUCTION OF PATHS.—See *GARDEN PATHS*.

CONTROLLING RUST FUNGI.—See *RUST FUNGI*.

CONVALLARIA.—See *LILY OF THE VALLEY*, and see also under this heading in *MEDICINAL HERBS*.

CONVOLVULUS (BINDWEED. Nat. Ord. Convolvulaceæ).—Although the many annual Convolvuli are extremely beautiful, and the hardy sorts are cultivated with great ease, the flowers are scarcely so popular as they were a generation ago. A spring or autumn sowing will suffice, but very rich soil should be avoided, or growth will be made at the expense of the flowers. Almost everyone has admired the native, perennial,

pink-flowered *C. arvensis*, producing sheets of flowers on dry banks. The species that has given practically all the dwarf garden varieties is the Southern European *C. tricolor*. Its broadly bell-shaped flowers vary very greatly in colour from pure white to velvety purple selfs, with many striped and shaded forms. Under cultivation and selection the habit of the plants has been so altered that little of the trailing character remains, but, instead, rounded mounds of neat foliage and gay blossoms are produced. These are very useful for flower or shrubbery borders or for summer bedding, provided they have a sunny site to grow in.

Annual Species.—The best are briefly described below :—

Convolvulus major.—See *Ipomoea purpurea.*

C. tricolor (Syn. *C. minor*).—This is the most popular sort. The variety *alba* has white flowers and *vittatus* striped ones. Garden varieties are not catalogued under name but under their colours, and they come very true to colour from seeds. Thus they can be used for colour schemes. The blue forms are very pleasing, and a deep crimson-violet form has many admirers. The height averages 1–3 ft.

COOKING APPLES.—See SELECTION OF VARIETIES, under months in which they ripen, in *APPLE.*

COOKING PEARS.—See list of PEARS FOR BAKING AND STEWING in *PEAR.*

COOKING PLUMS. — See list of PLUMS FOR COOKING in *PLUM.*

COPPER COMPOUNDS.—See *COPPER AND CUPRUM COMPOUNDS.*

COPPER AND CUPRUM COMPOUNDS.—Metallic Copper is of very little use to the gardener save for making lightning conductors for his greenhouses, or in the form of wire for renewing the fuses in his electric lighting or heating installation. Its compounds, however, form an important class, chiefly as fungicides, though the sulphate has been used as a fertiliser for lawns when added in extremely small quantities to lawn sands. In the copper compounds we have poisonous materials the use of which still requires much experiment, but it is believed that in this element there exists a cure for that fell disease Clubroot if a suitably mild material could be produced at a cheap rate. If applied to the soil, copper must be used in the remotest of small quantities, as up to now it has served to injure rooting rather than to encourage it.

As regards the compounds, Copper Carbonate, Copper Chloride, Copper Oxide, and Copper Phosphate have never yet come to the fore horticulturally, hence it is needless to give details concerning them here.

COPPER ACETATE.—This is not of much use to the gardener, though its basic salt popularly known as VERDIGRIS is sometimes used as an ingredient for indelible ink.

COPPER ACETO-ARSENITE.—This is usually a bright green solid, and is used to a certain extent as a fungicide. It is the chief ingredient in PARIS GREEN (see article on *INSECT PESTS: GENERAL METHODS OF DESTRUCTION*).

COPPER ARSENATE. — This has been suggested as a cure for Wart Disease of Potatoes, and also as a general fungicide. Unfortunately its use has not so far been satisfactory, and no striking results have been obtained. It has undoubted possibilities, however, and experiments with it should be carefully watched.

COPPER NITRATE.—This is a chemical with a future before it in horticulture—of that there can be little doubt. It is suggested that it could be prepared cheaply by adding

a solution of Calcium Nitrate (see article on *Lime Compounds*) to a strong solution of Copper Sulphate. This last is very cheap, as most gardeners know. Experiments with the present compound as a cure for clubroot and other diseases are, we understand, in progress, but it is too soon to say with any certainty that it fulfils what is hoped.

COPPER SULPHATE. — This, popularly known as Blue Stone, is the most important copper compound, and is largely used for the making of Bordeaux and Burgundy Mixtures, and as an ingredient in indelible ink. Its use in the former capacity is described in our article on *Spraying Mixtures and Fungicides*, while the latter use is briefly referred to in our notes on Ink in the article on *Garden Labels*.—E.

COPPER SULPHATE.—See *Copper and Cuprum Compounds* and *Weed Killers.*

CORAL BARBERRY (*Berberidopsis coralla*).—See *Climbing and Trailing Plants.*

CORAL-BERRIED DUCKWEED (*Nertera depressa*).—See *Nertera.*

CORAL-BERRY (*Symphoricarpus orbiculatus*).—See *Shrubs.*

CORAL ROOT (*Cardamine bulbifera*).—See *Cardamine.*

CORAL SPOT.—See *Diseases of Plants.*

CORBULARIA.—Now included in the genus *Narcissus.*

CORD GRASS (*Lygeum Spartum*).—See *Lygeum.*

CORD GRASS (*Spartina stricta*).—See *Spartina.*

CORDON FRUIT TREES.

No form of apple or pear tree is so suitable for the garden as the "Cordon," and well-grown cordon trees in full bearing well merit the name, which is derived from the French word denoting string or rope.

Advantages of Cordons. — The main advantages of cordon-grown trees are :—

1. The bearing stage is reached with little or no delay.

2. The maximum weight of fruit is grown on the minimum area of ground.

3. Nothing but the finest fruit is produced.

4. The trees are easily controlled and are within easy reach for thinning fruit, spraying, pruning, and general cultivation, not to mention for the final gathering.

No form is so suitable as the cordon for the average small garden, at the same time being equally suitable for the large one.

Management of Cordons.—First of all, of course, the ground should be carefully selected and made suitable for cordons. Naturally this form of tree does best in light, warm, friable soil, but if the soil is heavy clay it must be made lighter and warmer by the addition of mortar rubble, or burnt earth, and careful attention paid to drainage. On such soils the trees should be planted near the surface, and the soil moulded up to them, leaving the trees on a mound above the surrounding soil.

On the other hand, in very hot light gravelly or sandy soils, cordon fruit trees require attention during dry weather in the way of mulching and an occasional heavy soaking of water. In other respects the same methods of planting, spraying, thinning of fruit, and general cultivation hold good as in other forms of dwarf fruit trees.

Single Cordons.—These are the best of all forms. They consist of a one-stem tree carrying a number of spurs on which are the blossom and fruit.

The trees should be planted 2 ft. apart at an angle of 45° in single rows sloping towards the south, and 5 ft. left between rows. Each tree should be supported by three or four wires strained from stout posts at

each end of the row, and bamboo canes 6 ft. long should be tied to the wires at the same angle, the trees themselves being tied to the canes. As in all other forms very firm planting is essential for success.

Pruning consists of shortening each shoot (except the terminal or leading shoot) in late August or September to four or five leaves, cutting this again back in the winter to three eyes or a fruit bud. The *Lorette System of Pruning* is, however, more elaborate and quite ideal for cordons. This consists of pinching the young side shoots in June to six leaves; again pinching all growths from these shortened shoots in July; then in August cutting back to the "basal" buds of the young shoots from which will emerge a *dard* (immature fruit bud), or a fully matured fruit bud, thus hastening the appearance of fruit buds by a year or two. The "basal" buds are situated a quarter of an inch beyond the previous year's wood, *i.e.* in the first quarter of an inch of the current summer's growth.

The leading (terminal or extension) shoot of cordon fruit trees seldom requires shortening at any time, the angle at which it grows causing it to produce side-shoots along its entire length. As the trees grow longer they should be pulled down to a sharper angle, maintaining the total height of the row at about 6 ft., at the same time keeping each tree in the row at an equal distance from its neighbour.

Ties must be examined and renewed before they cut into the shoots, and fruit must be reduced to suit the strength and growth of the trees. As a rule, if a foot of new growth be made by the middle of June, the trees are not carrying more fruit than they can properly mature.

Over-cropping in any one year generally means little or no fruit the next; thus a moderate crop annually is the ideal.

What to Grow.—All varieties of Apples that "spur" well are suitable for this form, the few exceptions being the varieties that produce most of their fruit on the ends of short branches, such as *Irish Peach* and *Mr Gladstone*. *Lady Sudeley* and *Worcester Pearmain* require the leading shoots shortened about halfway each winter, as they do not produce side-shoots so freely as most varieties.

All Pears (except *Jargonelle*) succeed admirably as cordons, and this form is quite the best way of growing pears.

Plums, too, may be grown as cordons, but must not be side-pruned so closely, as they fruit mostly on short young branches. Rows of cordon plums more resemble a hedge, and really this fruit is more profitable grown as bushes and standards.

Cherries are also best grown as standards or bushes, as they are liable to resent the hard pruning necessary to keep to the cordon form. However, if this is done to cherries before the leaves drop, preferably in August, they will stand the hard pruning much better. They spur well on the old wood, but if pruned when dormant sometimes exude gum and become unhealthy. The *Morello* is the only variety that cannot properly be grown in cordon form. The Black Currant cannot be grown in this manner, for the same reason.

Manures for Cordons.—The use of highly nitrogenous manures is not recommended for cordons unless there is danger of exhaustion, such as is the case if they are carrying a very exceptionally heavy crop, or are approaching old age. An annual dressing of some bulky

manure lightly dug in during the autumn, and followed by sowings of phosphates such as bone-flour, in the spring, should be sufficient.

In the event of trees producing too much wood at the expense of fruit, due as a rule to over-manuring, they may be root-pruned in November in the manner described in our article on *Root Pruning*. This operation is seldom necessary if over-manuring be avoided, and if the trees are grafted upon the proper stocks for cordons. Care should be exercised when purchasing trees that the stocks used are English Paradise for apples, and Angers Quince for pears.

One word of warning may be profitably added. Owing to the small space occupied by this form of fruit tree, the amateur is often liable to plant too near ornamental and larger trees whose roots rob the ground which should be the property of the fruit trees and whose shade robs them of their proper share of sunlight. Apples, especially, require space and air, and more importance should be attached to their requirements in this way than is usually done. Although, of course, the distance varies somewhat according to circumstances, the cordons should not be planted less than 30 ft. away from the subjects just named.

Cordons on Walls.—Apples should never be grown as cordons on walls south of the Midlands, but may be very profitably so grown as such in the North. Cordon pears succeed admirably on south, south-east, and south-west walls in all parts of the kingdom. If the walls are high, such as those of houses or out-buildings, the cordons may be planted upright and a little closer together; the leading shoots should, in this case, be cut halfway back each winter in order to ensure side-growths. Cherries and Plums are best fan-trained on walls. Cordon Red and White Currants as well as Gooseberries are often planted on north walls to prolong their season, and south walls to advance their earliness. The general treatment is similar to that described for apples and pears.

Other Cordons.—Other forms or, rather, elaborated forms are *double* and *treble, diagonal* or *upright cordons*, which consist of two or three stems being taken up instead of one as is the case with the single cordon previously dealt with. These forms are not nearly so desirable, as in most cases one of the stems obtains the mastery at the expense of the other or others, and it requires very skilful manipulation to maintain the balance of strength. Pinching in summer the growing points of the stronger stems is the best method of control, and often requires doing several times.

Again, a form known as the *double horizontal cordon* is often used as edgings and consists of a double-shooted cordon, trained T shape, the top of the T being allowed to extend in both directions as far as space permits. This form may be called an espalier of one tier, but this tier is grown parallel with, and 1 ft. above, the ground. It is quite satisfactory, except that the difficulty of symmetrical control occurs as in the case of the last-mentioned types.

Again, there are the *Palmettes*, much grown in France, which are cordons of four or five diagonal stems; also the *grid-iron cordon*, with four or five upright stems all emanating from one horizontal base. These are elaborations of the double horizontal cordon above referred to, and the more elaborated the tree, the greater is the skill required to preserve balance and

symmetry. Other elaborated designs may be evolved on similar lines according to the fancy of the grower, but, as above mentioned, the most practical and profitable form, the easiest to train, and from which amateurs can produce the best results, is the single diagonal cordon.—W. P. S.

CORDONS: PRUNING OF.—See *PRUNING FRUIT TREES.*

CORDONS ON WALLS.—See *CORDON FRUIT TREES.*

COREAN PINE (*Pinus koraiensis*).—See *TREES.*

COREOPSIS (TICKSEED. Nat. Ord. Compositæ).—The ANNUAL SPECIES of this genus are slender plants, and though they often need a little support such as a few foot-high twigs afford, they are free flowering, elegant subjects, suitable alike for the border or for the reserve garden where plants are grown for the production of flowers for cutting. Rich brown and golden-yellow are the predominating colours. Although hardy in the southern counties, an autumn sowing cannot always be depended upon, unless the soil is light and well drained. Fine plants result from a March or early April sowing made in drills from whence the seedlings should be transferred to their flowering quarters when about 3 ins. high. A popular method of raising them is to treat them as half-hardy annuals and sow seeds in heat in February. The following are the most useful species :—

Coreopsis aristosa.—A yellow autumn flowering sort growing 2½ ft. high.

C. atkinsoniana (Syn. *Calliopsis atkinsoniana*).—A yellow sort with a brown centre, blooming throughout the summer, and growing 3 ft. high.

C. cardaminefolia.—A yellow and purple-brown summer flowering sort growing 2 ft. high. The dwarf form *C. c. nana* is very useful for edging, as it only grows 9–12 ins. in height.

C. coronata.—A yellow and crimson-brown, summer flowering, Texan sort, growing about 2 ft. high.

C. Drummondii (Syn. *C. diversifolia*).—A crimson and yellow summer flowering sort, making a very handsome garden plant. It grows 2 ft. high.

C. tinctoria.—A brown and yellow sort flowering all through the summer. Its variety *atropurpurea* is a handsome garden plant. Both have given many interesting and beautiful forms, some of which are quite dwarf, rarely more than 1 ft. high, with crimson-brown or yellow-brown flowers. A comparatively new race has starry blooms and is known as *Cactus-flowered*; *Golden Crown* is dwarf yellow and orange; while *Lemon Queen*, taller, is possibly a form of *C. Drummondii*. There is also a double or semi-double form with yellow and brown flowers.

Perennial Border Species.—These are useful hardy herbaceous plants for the border and shrub border. They succeed in ordinary garden soil in a sunny site, and may be propagated in the usual way by seeds sown in the summer, or division of the roots in the autumn or spring, at which times they may also be successfully planted. Quite a number of species have been described; of these we recommend the following, most of which are useful for cutting :—

Coreopsis auriculata.—This bears yellowish flowers in June and July, and grows 4–6 ft. high.

C. delphinifolia.—This yellow sort blooms in July and August, and grows 1 yd. high.

C. grandiflora.—This also is yellow, and blooms in August and

September. It grows about 3 ft. high.

C. lanceolata.—This is a biennial or short-lived perennial, producing yellow flowers in August and growing 1 yd. high.

C. latifolia.—This is similar to the above, but perennial.

C. rosea.—This is a pretty sort bearing red flowers in July and August, and growing 1½ ft. high.

C. senifolia.—This bears yellow flowers in August and September, and averages 3–4½ ft. high.

C. trichosperma (Syn. *C. aurea*).—This is a biennial or short-lived perennial, bearing yellow flowers in August and September, and growing about 1 yd. high.

C. tripteris (GOLDEN CROWN).—This is a useful tall-growing sort for the back of borders, shrubbery margins, etc. It produces yellow flowers in August and September, and often grows 6 ft. high.

C. verticillata.—This is a slender grower bearing pretty yellow flowers from July to August, on plants about 12 ins. high.

CORNEL (*Cornus Mas*).—See *SHRUBS.*

CORNELIAN CHERRY (*Cornus Mas*). See *SHRUBS.*

CORNFIELD SNAPDRAGON (*Antirrhinum Orontium*).—See footnote to *ANTIRRHINUM.*

CORNFLOWER (*Centaurea Cyanus.* Nat. Ord. Compositæ).—The Cornflower is a British plant, and often found growing rather plentifully in cornfields ; it has other common names such as BLUE-BOTTLE and BLUET. In good soil it will grow 3 ft. high ; of slender habit and with small leaves, it carries bright blue flowers. The type has been improved under cultivation ; white, pink, rose, pale blue, and deep blue varieties are obtainable, and these come true from seed. There is also a group of dwarfer varieties grown under the title of *Cyanus minor*, and which rarely exceed a height of 12 ins. ; *Emperor William* is one of the best of the blue forms. A still dwarfer selection is catalogued as *Cyanus nana compacta*, or as the Victoria strain ; these grow 9 ins. high, and there are rose and blue varieties. *Centaurea depressa*—known as KING OF THE BLUE-BOTTLES—is like a dwarf Cornflower with a more spreading habit ; its large blue flowers are crimson centred ; 1 ft. high. Cornflowers are easy to grow, and their culture is in every respect similar to the general culture of annuals given in our article *ANNUALS FOR ALL PURPOSES.*—C. H. C.

See also *MEDICINAL HERBS.*

CORNISH ELM (*Ulmus glabra cornubiensis*).—See *TREES.*

CORNISH HEATH (*Erica vagans*).—See *HEATHS* and *SHRUBS.*

CORNISH POLYPODY (*Polypodium vulgare cornubiense*).—See *FERNS AND FERN GARDENING.*

CORNUS.—For the best species see *SHRUBS* and *CLIMBING AND TRAILING PLANTS.*

COROKEA.—For the best species see *SHRUBS.*

CORONILLA (CROWN VETCH. Nat. Ord. Leguminosæ).—This is a genus of handsome free flowering greenhouse plants of easy culture, and herbaceous plants suitable for the rock garden. There are also shrubby and creeping species, which it would be beyond the scope of the present work to describe. The greenhouse species may be easily propagated by inserting cuttings under a hand-light or bell-glass during the summer months, very little heat being required. A suitable soil for both cuttings and established plants is two-thirds peat, one-third loam, and plenty of silver sand. Temperature required, 40–50° F. The two best sorts are :—

Coronilla glauca.—Fragrant yellow. Flowers from June to July. Height, 2 ft.

C. glauca variegata. — Yellow. Flowers from June to July. Height, 2 ft.

Rock Garden Species.—The three described below are attractive and bear pea-shaped flowers. They thrive in loamy soil, and are easily propagated by the division of the roots in the autumn, or by seeds which germinate freely if sown in gentle heat in March.

Coronilla cappadocica (Syn. *C. iberica*).—This has prostrate stems well clothed with leaves. Flowers bright yellow. Site sunny. Soil deep loam. Flowering Period, June to July. Height, 3 ins.

C. minima.—This is a very dwarf species. Flowers yellow. Site sunny. Soil deep loam. Flowering Period, June to July. Height, 2 ins.

C. varia.—This forms a bushy plant, the juice of which is poisonous. Flowers bright rose. Site sunny. Soil ordinary loam. Flowering Period, June to July. Height, 18 ins.

See also *SHRUBS.*

CORONOPUS.—Now included in the genus *SENEBIERA.*

CORROSIVE SUBLIMATE.—See MERCURIC CHLORIDE in *MERCURY COMPOUNDS.*

CORSICAN HEATH (*Erica stricta*).—See *HEATHS.*

CORSICAN PINE (*Pinus Laricio*).—See *TREES.*

CORSTORPHINE PLANE (*Acer Pseudoplatanus flavo-marginatum*). — See *TREES.*

CORTADERIA (Nat. Ord. Gramineæ). — This is the new name for the genus *GYNERIUM*, on which a separate note appears elsewhere. The best species is *C. argentea* (Syn. *G. argenteum*), the well-known PAMPAS GRASS. This is described under *G. argenteum* in our article on *ORNAMENTAL GRASSES.* A species not previously included in Gynerium, as far as we know, is *C. conspicua*, the SILVERY REED-GRASS, a very useful species for the wild garden.

CORTUSA (BEAR'S-EAR SANICLE. Nat. Ord. Primulaceæ).—These are interesting plants of the Primula family. They thrive in shady positions in deep rich soil in the rock garden, and are propagated by division of the roots in autumn or spring and by seed in spring. Only one species is worth growing.

C. Matthioli.—Leaves rounded in rosettes. Flowers purple in drooping umbels. Site half-shade. Soil sandy leaf-soil. Flowering Period, May to June. Height, 9 ins.

CORYANTHES.—See *ORCHIDS.*

CORYDALIS (FUMITORY. Nat. Ord. Papaveraceæ).—A useful genus of hardy annual, perennial border, and rock plants. With the

annuals we need not trouble here. The border sorts like shaded sites, and are not hard to propagate by division in the usual way in the autumn or spring. They may also be raised from seeds in the manner described in our general article on *PERENNIALS*.

Perennial Border Species.—Only a few of the many can be described here :—

Corydalis angustifolia.—A purple March blooming sort about 12 ins. high.

C. bulbosa.—A synonym of *C. solida*, which see.

C. Cava.—A synonym of *C. tuberosa*, which see.

C. cheilanthifolia.—A popular yellow sort blooming from May to July, and averaging 12 ins. high.

C. Marschalliana.—A purple February flowering sort about 12 ins. high.

C. pallida.—A useful yellow March blooming sort growing about 1½ ft. high.

C. pauciflora.—A similar sort in all its characters to *C. Marschalliana.*

C. Semenowii.—A bright yellow sort blooming in March and April. The height averages 1½ ft.

C. solida (Syn. *C. bulbosa*).—A pink sort blooming in February and March. Its average height is 12 ins.

C. tuberosa (Syn. *C. Cava*).—This can be had in purple and pure white. It is a desirable sort flowering from February to May, and averages 12 ins. high.

Rock Garden Species.—The five described below are splendid, and are propagated by division of roots in autumn or spring :—

Corydalis bracteata.—Leaves deeply divided. Flowers sulphur-yellow. Site, half-shade. Soil deep well-drained loam. Flowering Period, May to June. Height, 6 ins.

C. capnoides.—A bushy plant. Flowers creamy-yellow. Site, half-shade. Soil rocky, or old walls. Flowering Period, May to October. Height, 12 ins.

C. lutea (YELLOW FUMITORY).—A bushy plant with deeply divided leaves. Flowers clear yellow. Site, half-shade. Soil rocky, or old walls. Flowering Period, May to October. Height, 12 ins.

C. nobilis.—A handsome bushy species. Flowers golden-yellow, with dark centre in dense heads. Site, half-shade. Soil deep sandy loam. Flowering Period, May to June. Height, 9 ins.

C. thalictrifolia.—A plant with much divided elegant foliage. Flowers clear yellow in long racemes. Site, half-shade and sheltered. Soil well drained and gritty. Flowering Period, May to September. Height, 9 ins.

CORYLOPSIS.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

CORYLUS.—For the best species see *TREES*.

CORYPHA.—See LIVISTONA in *PALMS*.

COS LETTUCE.—See *LETTUCE*.

COSMOS.—See *ANNUALS, HALF-HARDY : LIST OF*, and *PERENNIALS, HALF-HARDY : LIST OF*.

COSSUS.—See GOAT MOTH in *INSECT PESTS*.

COTA.—Now included in the genus *ANTHEMIS*.

COTONEASTER.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

COTTAGE GARDENS.—Our remarks on *VILLA GARDENING* apply equally to these.

COTTAGE TULIPS.—See under VARIETIES in *TULIPS*.

COTTAGER'S KALE.—See *BORECOLE or KALE*.

COTTON THISTLE.—See *ONOPORDON*.

COTTON WEED (*Diotis*. Nat. Ord. Compositæ).—This moorland plant is sometimes grown in the more peaty portions of the wild

garden, but as it is of very little value we do not recommend it being troubled with.

COTTONWOOD (*Populus deltoidea*).—See *TREES*.

COTYLEDON (PENNYWORT.[1] Nat. Ord. Crassulaceæ).—A genus of succulent plants, growing well in dry positions in the rock garden. They are propagated by division in autumn or spring, or by seeds in heat in spring.

C. chrysanthus.[2]—Leaves hairy in rosettes, forming masses. Flowers cream coloured, in corymbs. Site open and sunny. Soil gritty. Flowering Period, June to July. Height, 6 ins.

C. Pestalozzae.—Leaves in rosettes. Flowers pink. Site sunny. Soil gritty. Flowering Period, June to October. Height, 6 ins.

NEW VARIETY.

Cotyledon simplicifolia.—This is a pretty hardy sort, with leathery leaves and yellow flowers in drooping racemes.

COTYLEDONS.—See under LIFE-HISTORY OF FLOWERING PLANTS in *PLANT PHYSIOLOGY*.

COUCH GRASS.—A persistent perennial weed. See *AGROPYRON*. For MEANS OF CONTROL see *WEEDS*.

COUVE TRONCHUDA or **Portugal Cabbage** (*Brassica oleracea costata*. Nat. Ord. Cruciferæ).—This is quite distinct from the ordinary cabbage, and less able to withstand severe frost. It forms a most delicious winter and early spring vegetable. The green portion of the large leaves is far sweeter to the taste than even the best among ordinary cabbage, and the stout stems of these leaves make a really good substitute for Seakale.

Culture.—Sow in the open garden in early spring and treat as advised in article on *BROCCOLI*.—F. R. C.

COW MANURE.

Undoubtedly cow manure is, if properly managed, a valuable manure for many garden purposes, especially where the soil is very light, but its sticky nature and its effect on the stronger soils deters it being used as much as horse manure. Fresh green cow manure is but little used save for making liquid manure, and for deeply digging into very hungry soils; it is a very heavy material and, though consisting largely of humus, contains very little plant food. As a rule in its fresh state it is useless for mulching on account of the fact that a hard skin sets on the surface in hot weather.

Cow Dung Stacks.—Travelling up and down the country it is rare that one sees a proper stack of cow dung. Usually the material is thrown together in a loose heap just as it is wheeled away from the winter cow byres. Pools of water are seen round the heap, soaking away to waste, and the heap is in no way protected from the winter rains. It is not to be wondered at that the resulting material is mild—too mild very often for general garden manuring—as the plant food has been washed out.

The ideal method is to choose a site for the heap protected by a wall from the prevailing winds, and to put down a sloping base of flags or, better still, concrete with a drain at the two lowest corners. This drain should not lead into a sewer, but into a sump or tub from which the rich green or black liquid can be frequently pumped up. The heap itself should be built in the shape of a span-roofed glass-house and the dung made as firm as

[1] Or NAVELWORT of some authorities.—EDITOR.

[2] The HOUSELEEK PENNYWORT.—EDITOR.

possible. One or two holes should be left in the top for the liquid drainings to be pumped into, and the rest of the heap should be covered with soil or with boards to protect it from the weather. After about six weeks of rotting in this manner, the material may be used, more especially for vegetables, but the longer it rots the better it will be. After about six months of this treatment a beautifully mild but very rich material will be obtained for use as a top-dressing to or a manure for flower-beds, roses, and so on. It then proves a valuable cooling mulch for fruit trees. It can be used at the rate of 3–5 cwt. per sq. rod, the smaller quantity being for mulching and the larger for digging in.

Potting Dung.—Gardeners often require cow manure to add to their potting soils, and while fairly fresh material can be used for such gross feeders as tomatoes, generally speaking the older the material is the better. That which has been allowed to rot in a protected heap for twelve to eighteen months will prove the most suitable, and it is far better to make arrangements to keep the manure for that period than to have to purchase it and pay the top price asked for it over a nurseryman's counter.

Sawdust Manure.—The difficulty of obtaining straw has compelled many cow-keepers to bed their beasts on sawdust, and consequently a mixture of sawdust and dung is often sold to gardeners for manure. This material should be avoided; it is all very well for the fields, but brings trouble in its track if used in the garden. On account of the sloppy nature of cow dung it is quite impossible to arrange to keep the droppings separate from the sawdust, as they always absorb a quantity of it. Where the material has to be used, however, it should be very old indeed, not less than twelve months at any rate, and better still two years. Lime should be freely used on the land and the material applied sparingly, certainly at no greater rate than 3 cwt. per sq. rod.

Cow manure will have to come into more general use on account of the reduction in horse traffic due to increased motor traction, thus gardeners should understand its limitations. It may be well to add for the sake of beginners that where cow dung is used for liquid manuring, the first water poured over the bag of dung in the liquid manure barrel should be boiling water, in order to kill the numerous pests it contains.—E.

COW PARSNIP.—See *HERACLEUM*.

COWBERRY (*Vaccinium Vitis-idaea*). See *SHRUBS*.

COWSLIP (*Primula officinalis*).—See *PRIMULA*.

CRAB APPLE.—For the best sorts see PYRUS in *TREES*.

CRAB GRASS.—See *ELEUSINE*.

CRACCA.—Now included in the genus *VICIA*.

CRACK WILLOW (*Salix fragilis*).—See *TREES*.

CRAESIA.—See under ROSE GRUBS in *INSECT PESTS*.

CRAMBE (KALE. Nat. Ord. Cruciferæ).—This is a genus of hardy herbaceous or tuberous perennials of easy culture, but not of great value for garden decoration. The best for this purpose is *C. cordifolia* (Syn. *C. kotschyana*), a white May flowering plant about 4 ft. in height. *C. pinnatifida* (Syn. *C. orientalis* of some authorities) is rather similar. *C. maritima* is the well-known vegetable *SEAKALE*, on which a separate article is given. The SPANISH KALE (*C. hispanica*), may also be grown and used in the same way. The roots of *C. Tataria*

are used as a vegetable abroad, but not in this country.

CRANBERRY.—The genus Oxycoccus and *O. palustris*. See *SHRUBS*.

CRANE FLIES.—See *INSECT PESTS*.

CRANES-BILL.—A popular name for the perennial border Geraniums. See *GERANIUM*.

CRASPEDARIA.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

CRATAEGUS.—For the best species see *CLIMBING AND TRAILING PLANTS* and *TREES*.

CREEPING BUTTERCUP.—A perennial Weed. For MEANS OF CONTROL see *WEEDS*.

CREEPING CROWFOOT (*Ranunculus repens*).—See note at end of *RANUNCULUS*.

CREEPING FORGET-ME-NOT (*Omphalodes verna*).—See *OMPHALODES*.

CREEPING JENNY (*Lysimachia Nummularia*).—See *LYSIMACHIA*, also *WATER GARDEN: PLANTS FOR THE*.

CREEPING THISTLE.—A perennial Weed. See *CNICUS*. For MEANS OF CONTROL see *WEEDS*.

CREEPING WINTERGREEN (*Gaultheria procumbens*).—See *GAULTHERIA* and *SHRUBS*.

CREOSOTE.—See *WOOD PRESERVATIVES*.

CRESS.

This is a name applied to an enormous number of garden plants. The following is a list of the most important, the authorities for the names being those at Kew:—AMERICAN CRESS (*Barbarea praecox*); BITTER CRESS (*Cardamine amara*); PENNY CRESS (*Thlaspi arvense*); PEPPER CRESS (*Teesdalia nudicaulis*); PURPLE ROCK-CRESS (*Aubrietia deltoidea*, and other species); ROCK-CRESS (the genus *Arabis*); WALL CRESS (*Arabis albida*); WART CRESS (the genus *Senebiera*); WATERCRESS (*Nasturtium officinale*); WHITLOW CRESS (*Lepidium Draba*); and WINTER CRESS (*Barbarea officinalis*). Most of these are referred to in their proper places under the common or botanical names. The salading crop known merely as CRESS, always grown with another salading crop, MUSTARD, and the WATERCRESS are dealt with in our article on *SALAD PLANTS*.

CRESS: Common and Water.—See MUSTARD AND CRESS and WATERCRESS in *SALAD PLANTS*, and see also *LEPIDIUM*.

CRESTED HAIR GRASS.—See *KOELERIA*.

CRETAN MULLEIN (*Celsia cretica*. Nat. Ord. Scrophulariaceæ).—This is one of about thirty species in a genus of hardy and half-hardy biennials or perennials, bearing yellow, purple, or red flowers, on long spikes. They are distinguished from Verbascum by having only four stamens, the latter having five.

Culture.—This is quite simple. Sow the seeds on a well-prepared bed in the open, in June, and thin out to 2 ft. apart, or sow in a bed and transplant into the permanent positions when a few rough leaves have been made. *Celsia cretica*, with its yellow flowers, is also very handsome for the greenhouse, when grown in pots. Where the soil is very heavy it should be wintered in a cold frame and planted out in spring. Out of doors the plants flower in June, and vary from 2 ft. to 6 ft. in height.

CRETAN SPIKENARD (*Valeriana Phu*).—See *VALERIANA*.

CRICKET BAT WILLOW (*Salix alba caerulea*).—See *TREES*.

CRIMEAN SNOWDROP (*Galanthus plicatus*).—See *SNOWDROP*.

CRIMSON CHINA ROSE (*Rosa indica sanguinea*).—See *ROSE SPECIES*.

CRIMSON CLOVER (*Trifolium incarnatum*).—See *TRIFOLIUM*.

CRIMSON FLAG.—See *KAFFIR LILY*.

CRIMSON LEAF.—See *SHORTIA*.

CRIMSON PINK (*Dianthus atrorubens*). See *DIANTHUS*.

CRIMSON SATIN FLOWER (*Brevoortia Ida-Maia*). See *BREVOORTIA*.

CRINUM (Cape Lily. Nat. Ord. Amaryllidaceæ).—This is a valuable addition to bulbous flowering plants for the greenhouse, with stems 2–3 ft. high, producing eight to twelve blooms. It requires rich loam, peat, and sand, and is propagated by offsets and seed in spring. Temperature needed, 45–55° F.

Greenhouse Species. — *Crinum cruentum.*—Pink. Flowers in July. Height, 2–3 ft.

C. longifolium.—Rosy red. Flowers in July. Height, 2–3 ft. This may also be grown out of doors in a sheltered herbaceous border.

C. Macowani.—White, tinged red. Flowers in January. Height, 2–3 ft.

C. Moorei.—Rose. Flowers in March and September. Height, 2–3 ft.

C. Powellii.—Rosy white. Flowers in July. Height, 2–4 ft. Its variety *album* has white flowers.

CRIOCERIO.—See Asparagus Beetle in *Insect Pests.*

CRITHMUM MARITIMUM.—See *Samphire.*

CROCUS (Nat. Ord. Iridaceæ).

History.—The Crocus family is a large one, and has been known in one part of the world or another from the earliest times of which we have any historical record. Crocus colour or saffron was the imperial colour of ancient Chinese civilisation. The rich glow of a mass of the ordinary garden yellow crocus attracted poor Forbes Watson, for in one of his exceptionally charming essays he writes: "The Yellow Crocus is a perfect flower, leaving nothing that we could wish to add to or alter" (*Flowers and Gardens,* page 33, first edition). This large yellow variety (along with the large purple, the striped, and the white) is alone thought of by many people when they think of a Crocus. These so-called Dutch or Florists' Crocuses, however, by no means represent anything like the whole family. There are numerous species, which, although as a rule they have smaller and more delicate-looking blooms, are even more beautiful as individuals, and are by no means to be despised for the show many of them are capable of making when massed together. Moreover, some of them begin to flower in the autumn, from which time there is an orderly succession of flowers until the last whites of the Dutch varieties finish the season. These species are now coming very much to the front, and already there are, for example, hybrids of *Crocus chrysanthus* on the market, *e.g. E. A. Bowles, Siskin,* and *Yellow Hammer.* As most Crocuses seed freely, the production of new varieties by cross fertilisation and selection offers a most interesting hobby to anyone who can give a little time and attention to them.

Culture.—Any good fairly light garden soil suits the Crocus. It is obvious that the autumn and winter flowering varieties must be planted in June or July, and that warm, sheltered nooks should be chosen if they are to be seen at their best. Failing this, they should have the protection of a cold frame. Two or three frames 6 ft. by 4 ft., with autumn and winter species of Crocus planted out in them, afford almost constant bloom all through the darkest days of the year, if the selection is well made. Some of the early spring flowering species, such as *Crocus Sieberi,* do very well in pots, if grown from start to finish with a minimum of heat and plenty of air. *Dorothea,* a Dutch variety, is also exceptionally good as a pot plant.

Species and Varieties.—These may be divided into (1) Dutch or Florists' Varieties; and (2) Species and Species Varieties, or Hybrids. The height of all Crocuses rarely exceeds 6 ins.

DUTCH VARIETIES: *Mauve.*—Dorothea.

Purple.—Cæsar, Hero, and *purpurea grandiflora.*

Striped.—Edina, Margot, Mikado, Sir W. Scott.

White.—Kathleen Parlow, May, Mt Blanc, White Lady.

Yellow.—There is only one yellow called the Yellow Dutch. This never seeds, hence all propagation must be by increase of the corms.

SPECIES AND HYBRIDS: AUTUMN-FLOWERING:—*Crocus asturicus.*—Purple.

C. longiflorus (Syn. *C. odorus*).—Soft lilac, deeper feathering at base of flower.

C. pulchellus.—Lavender.

C. sativus (SAFFRON CROCUS).—Purple-lilac.

C. speciosus.—Blue-purple. *Aitchisonii* is a much improved sub-variety.

C. zonatus.—Rosy-lilac, with a yellow and orange zone in the centre and tube.

SPRING-FLOWERING:—*Crocus aureus.*—Golden-yellow.

C. biflorus.—White - feathered violet.

C. chrysanthus.—Shades of yellow, but varies a good deal.

C. Imperati.—Purple, outside fawn.

C. tommasinianus.—Lavender.

C. Sieberi.—Bluey-lilac.

C. susianus.—Deep yellow or dark orange, with brown flames on the exterior.—J. J. & E.

CROCUS, AUTUMN, and CROCUS, SAFFRON.—See *COLCHICUM*, also under CROCUS in *MEDICINAL HERBS.*

CROP REQUIREMENTS.—See *MANURES.*

CROPPING.—See *ROTATION OF CROPS AND DOUBLE CROPPING.*

CROWFOOT.—See *WATER GARDEN: PLANTS FOR THE.*

CROWN DAISIES.—See *CHRYSANTHEMUM: ANNUAL SPECIES.*

CROWN GALL.—See *DISEASES OF PLANTS.*

CROWN GRAFTING.—See GRAFTING in *PROPAGATION OF PLANTS.*

CROWN IMPERIAL (*Fritillaria Imperialis.* Nat. Ord. Liliaceæ).—This is a member of the Fritillary family, and has been an inhabitant of British gardens for a very long time. It is a native of Persia, and seems to have come to us *via* Vienna. Well-cultivated specimens grow about 3 ft. in height. The leafy tuft at the top of the stem, with the circle of large pendulous flowers immediately beneath it, are features well known to all gardeners. Parts of the plant have an unpleasant smell, hence the name of STINK LILIES.

Culture.—Crown Imperials like a rather stiff, rich loam, and semi-shade. Bulbs should be planted 6 ins. deep, and for a good effect, in clumps of four to eight, each one 8 ins. from its neighbour. An annual top-dressing of old manure and leaf-mould is of great benefit, as they dislike root disturbance, and should not be moved more than once in every five years.

Varieties.—There are not many of these, but in any case the double sorts are not recommended.

Fritillaria Imperialis.—This is a splendid red sort, flowering in May, and averaging about 3½ ft. in height.

Varieties of it are *maxima lutea* (yellow), and *maxima rubra* (red).

There are a few named forms, such as *Aurora* (orange-red); *Orange Brilliant* (orange and buff); and *Red Crown-Upon-Crown* (red, with two or more whorls of flowers). All these varieties of the Crown Imperials bloom in May, and grow about 3 ft. high.—J. J. & E.

CROWN VETCH.—See *CORONILLA.*

CROWNED CAMPION (*Lychnis coronaria*).—See *LYCHNIS.*

CRUCIANELLA.—See *PHUOPSIS.*

CRUCIFER MIDGE.—See *INSECT PESTS.*

CRYPTOCERAS.—Now included in the genus *CORYDALIS.*

CRYPTOCOCCUS.—See FELTED BEECH Coccus in *INSECT PESTS.*

CRYPTOGRAMME.—For the best species see *FERNS AND FERN GARDENING.*

CRYPTOMERIA.—For the best species see *TREES.*

CUBICAL CONTENTS OF GREENHOUSES.—See under VOLUMES in *ARITHMETIC AND GARDENING.*

CUCKOO GRASS (*Luzula campestris*). See *LUZULA.*

CUCUMBER FRAMES.—See *GREENHOUSES AND FRAMES.*

CUCUMBER LEAF BLOTCH DISEASES.—See *DISEASES OF PLANTS.*

CUCUMBER AND TOMATO HOUSES. See *GREENHOUSES AND FRAMES.*

CUCUMBER TREE (*Magnolia acuminata*).—See *TREES.*

CUCUMBERS (Frame).

These require a bed made up as mentioned under *MELON*, one plant to a light 6 by 4 ft. will be found sufficient. Stop and train the shoots as recommended, removing surplus shoots; a regular supply of fruit is what is required. Periodical attention is needed in regard to stopping and thinning of the shoots or they soon become crowded. Night temperature may be increased to 70° F. or 75° F., with a rise of 10° or 15° during day. Increase the moisture supplied by syringing and damping.

Varieties.—Good reliable sorts are: —Every Day, Rochford Market, and Telegraph.—F. J.

CUCUMBERS: Indoor (*Cucumis sativus.* Nat. Ord. Cucurbitaceæ).—The cultivation of the cucumber is important in every garden, and though comparatively easy to grow during the summer months, much care and attention is necessary to keep up a regular supply throughout the winter months. For this purpose, light, heat, moisture, and rich compost are needed, with a low span-roofed pit or lean-to house. Bottom heat-pipes are the best for winter supplies; these can be regulated and kept as near 75° F. as possible. A little ventilation may be given at the top of the house on fine days. The night temperature must not fall below 60° F., or the day temperature below 70° F. Even with bottom heat-pipes, a bed of manure should be made up and the compost placed on top; this assists the maintenance of warmth and natural moisture. Two parts loam, with one of leaf-mould, with rich top-dressings of loam, and a little rotten manure as the plants gain strength, will be found suitable. Sow the seeds as recommended for melons, and set out the plants on mounds of compost about 4 ft. apart avoiding overcropping of the plants especially during the winter months. Tie up the plants loosely and pinch out the points when they have made about 3 ft. of growth; side-shoots may be stopped at two or three leaves, all other young shoots being treated similarly, until the roof is covered with fruit-bearing shoots.

Careful watering is necessary at first, but after the plants have filled the border with roots, light rich top-dressings are necessary, and more copious supplies of water as warmth and light increase.—F. J.

CUCUMBERS: Outdoor (*Cucumis sativus*. Nat. Ord. Cucurbitaceæ).—In addition to the varieties of cucumbers useful only for cultivating in heated houses or garden frames, there are two others quite distinct in appearance and manner of growth which in favourable seasons may be depended upon to give very satisfactory crops grown entirely in the open air. The best known of these are the *Ridge Cucumbers*, so largely grown for the London and other markets, and even though the latest additions to the varieties lack both size and appearance compared with others grown under glass, they are most useful in mixed salads, or for cultivation by those having no better means of obtaining home-grown supplies.

Culture.—If early fruit is desired seed should be sown in a greenhouse or sunny window early in April, and the plants put into open quarters during the first week in June. Such plants usually give very fine fruit by the middle of July, but for all ordinary purposes, the seed may be sown in the open air any time after the end of April.

A good plan to follow with these is to prepare a portion of ground by deep digging and manuring as early in the spring as possible, treading this fairly firm, and if dry giving a good watering just before sowing.

Draw out a drill 2 ins. deep with the corner of a hoe and press in a good plump seed every 2 ft. or so of the row (two or three seeds in each place will be better). Reduce where all seeds germinate to not less than 2 ft. apart, and during dry weather keep the plants well supplied with rain or soft water.

The fruits should be cut before they begin to show signs of turning yellow. If left uncut after this stage is reached, not only will they be of little table value, but their presence on the plant prevents the development of others.

Varieties.—The difference between the various varieties in this section is very considerable, the cream of these being found in:—King of the Ridge, Perfection Ridge, and Washington Ridge.

Japanese Cucumbers are a later introduction, but find much favour with cottagers. They produce fruit very early and in good numbers. Although these lack the size of the Ridge varieties the fact that they are more freely produced makes up for this.

Sow the seeds in a pan or bed early in April, but do not attempt planting out until all danger from frost is past.

Give each plant a few shovelfuls of well-rotted manure, burying this a foot below the surface, covering with any ordinary garden soil.

When planting always leave a slight depression in order that water may be freely given without waste. Provide each plant with a good stout pole or stick, and every evening following a warm day give the foliage a sprinkle overhead through a rosed watering can.

If, as usually is the case, the plants produce their fruit too freely for home consumption, do not be tempted to allow these to remain on after reaching a fair size, and on no account attempt to save seed until quite the end of the season, this being only possible at the expense of many fruits.—F. R. C.

CUCURBITA (Nat. Ord. Cucurbitaceæ).—This is a genus of

useful half-hardy plants. *C. maxima* is the common PUMPKIN, so useful for pies, etc. *C. Pepo* is the GOURD, used similarly to the Vegetable Marrow and Pumpkin. See article on *PUMPKINS AND GOURDS*. *C. Pepo ovifera* is the VEGETABLE MARROW, a most useful vegetable, or is it a fruit? See article on *VEGETABLE MARROW*.

CUDWEED (*Gnaphalium*. Nat. Ord. Compositæ).—The Cudweeds would hardly be worthy of mention as useful hardy annuals were it not that many plant lovers have a weakness for "everlasting" flowers. The yellow flowers are closely placed in clusters; they appear in July, and are long-lasting when dried. The plants grow about 12 ins. high, and the best annual species is *G. obtusifolium*. See also article on *LEONTOPODIUM*.

CULINARY CROPS.—See *KINDS OF CROPS*.

CULINARY PEA.—See *PISUM*. See also *PEAS*.

CULTIVATORS.—See *GARDEN APPLIANCES*.

CULTURE OF GREENS.—See *GREENS: WINTER AND SUMMER*.

CULTURE SOLUTION.—See *PLANT PHYSIOLOGY*.

CUNNINGHAMIA.—For best species see *TREES*.

CUPHEA (Nat. Ord. Lythraceæ). This is an extensive genus of hardy annuals, stove annuals, stove evergreens, and half-hardy shrubs. As, however, there are many better things, we do not propose to describe any species here.

CUPRESSUS.—For the best species see *TREES*.

CUPRUM COMPOUNDS.—See *COPPER AND CUPRUM COMPOUNDS*.

CURATIVE PROPERTIES OF RESURRECTION PLANT.—See *RESURRECTION PLANT*.

CURRANT.—See *BUSH FRUITS*, also under RIBES in *SHRUBS*.

CURRANT CLEARWING.—See *INSECT PESTS*.

CURRANT AND GOOSEBERRY SAWFLIES.—See *INSECT PESTS*.

CURRANT LEAF SPOT.—See *DISEASES OF PLANTS*.

CUSCUTA (DODDER. Nat. Ord. Convolvulaceæ).—This is a genus of hardy plant parasites, bearing white sweet-smelling flowers. *C. Epilinum*, *C. Epithymum*, *C. europaea*, and *C. reflexa* are grown at Kew. These attain a length—it can hardly be called a height on parasitic plants—of about 12 ins. When plants are troubled by them, it is usually a sign of weakness and unhealthiness. The remedy is good culture and the use of mild stimulants.

CUSHION PINK.—See *ARMERIA* and *SILENE: ROCK GARDEN SPECIES*.

CUTTING: FLOWERS FOR.—See *FLOWERS FOR INDOOR DECORATION*.

CUTTING: FLOWERS UNSUITABLE FOR.—See *FLOWERS UNSUITABLE FOR CUTTING*.

CUTTING: ROCK PLANTS FOR.—See ROCK PLANTS FOR CUTTING in *ROCK PLANTS FOR ALL PURPOSES*.

CUTTING OF TREES: LAW AS TO. See *GARDENING LAW*.

CUTTINGS.—See CUTTINGS in *PROPAGATION OF PLANTS*.

CUTTINGS OF BEDDING PLANTS.—See *BEDDING PLANTS: CULTIVATION OF*.

CYANAMIDE.—See CALCIUM CYANAMIDE in *LIME COMPOUNDS*, and NITROLIM under NITROGENOUS MANURES in *MANURES*.

CYANANTHUS (Nat. Ord. Campanulaceæ).—A prostrate growing plant with numerous stems terminating with large flowers. It requires a moist but well-drained position in the rock garden, and is propagated by means of cuttings in July, by seeds in spring, or division in autumn. We recommend:—

C. lobatus.—Tufted and forming a mat. Flowers bluish-purple,

large. Site shade. Soil sandy peat. Flowering Period, June to September. Height, 2 ins.

CYANIDE OF LIME.—See under CALCIUM CYANAMIDE in *LIME COMPOUNDS*.

CYANIDE OF POTASH.—See POTASSIUM CYANIDE in *POTASH AND POTASSIUM COMPOUNDS*.

CYANIDE OF SODA.—See SODIUM CYANIDE in *SODA AND SODIUM COMPOUNDS*.

CYANUS MINOR.—See *CORNFLOWER*.

CYCLAMEN (SOWBREAD. Nat. Ord. Primulaceæ).—Florists' section: greenhouse perennials. Height, 9–12 ins.

Soil.—Turfy loam, peat, and leaf-mould in about equal parts, with some rough silver sand. Propagate by sowing seeds in the autumn in pots or pans.

Culture.—Sandy loam, peat, and a little leaf-mould should be used till the seedlings are potted off individually. Cover the seeds lightly, keeping the soil shaded and uniformly moist till germination takes place. A temperature of 65° F. is suitable. As soon as the first rough leaf is formed, pot the young plants into "thumbs" and transfer later to 3-inch pots. About midsummer the final shift should be given into 5½- or 6-inch pots. At this stage a moist atmosphere is beneficial, and, if the weather is dry, syringing after sundown will greatly aid development. The plants will bloom from about mid-November till early in March. During the summer, shading from direct sun heat is essential, and as the flowering period approaches, it is desirable to give occasional doses of weak liquid manure; sheep manure giving, perhaps, the best results. A temperature of about 55–60° F. is required while the plants are in bloom. Greenfly and thrip are sometimes troublesome, but fumigation will keep the former in check, and the latter will not develop into a pest if the house is kept moist as advised.

Varieties.—Cherry Ripe, Crimson St George, Giant White, Mrs A. Buckstone, Mrs L. M. Greaves, Salmon Queen.—J. L. G.

CYCLAMEN: Rock Garden Species. The hardy section of this genus includes many species valuable for the rock garden and shady fern border, though none is suitable for the perennial border. The foliage is in most cases marbled with silver. Propagation by means of seeds sown in a little heat in spring is easy. The plants thrive best in shady corners amongst other low growing plants, and those described below are undoubtedly the best.

Cyclamen Coum.—This has dark-green kidney-shaped leaves. Flowers crimson. Site shade. Soil sandy loam. It is a flowering bulb or corm blooming from January to March. Height, 3 ins.

C. Coum album has white flowers.

C. europaeum.—Leaves large, faintly zoned with silver. Flowers crimson, sweetly scented. Site shade. Soil sandy loam. Flowering Period, August to November. Height, 3 ins.

C. hederaefolium.—Syn. *C. repandum.*

C. ibericum (Syn. *C. vernum*).—Similar to *C. Coum*, but leaves are zoned with white. Flowers crimson with purple blotch. Site shade. Soil sandy loam. Flowering Period, January to March. Height, 3 ins.

C. ibericum Atkinsii has white flowers with crimson centre.

C. neapolitanum.—A handsome species with marbled foliage. Flowers bright rose with violet-crimson centre. Site shade. Soil sandy loam. Flowering Period,

August to September. Height, 4–6 ins.

C. neapolitanum album has pure white flowers.

C. repandum (Syn. *C. hederaefolium*).—Leaves Ivy-like, with silver zone. Flowers rose-crimson. Site shade. Soil sandy loam. Flowering Period, April to May. Height, 4 ins.

C. repandum album has pure white flowers.

C. vernum.—Syn. *C. ibericum.*

W. I.

CYCLAMEN-FLOWERED DAFFODIL (*Narcissus cyclamineus*).—See *NARCISSUS SPECIES.*

CYCLODIUM.—Now included in the genus ASPIDIUM, for which see *FERNS AND FERN GARDENING.*

CYCLOPELTIS.—Now included in the genus ASPIDIUM, for which see *FERNS AND FERN GARDENING.*

CYCNOCHES.—See *ORCHIDS.*

CYDONIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

CYLINDERS, CAPACITY OF.—See CAPACITY OF CYLINDERS under VOLUMES in *ARITHMETIC AND GARDENING.*

CYMBIDIUM.—See *ORCHIDS.*

CYNARA (Nat. Ord. Compositæ). This is a genus of hardy biennial or perennial turnip-rooted and tuberous-rooted plants of no beauty for garden decoration. *C. Cardunculus* is the *CARDOON,* on which a separate article is given; and *C. Scolymus* is the GLOBE ARTICHOKE, the culture of which is described in our article on *ARTICHOKES.*

CYNOGLOSSUM (HOUND'S TONGUE. Nat. Ord. Boraginaceæ).—One quite charming member of the Hound's Tongue family deserves wider popularity than it at present receives. This is the annual *C. Wallichii* (Syns. *C. calycinum, C. membranaeum,* and *C. microcarpum*). The genus is closely allied to *OMPHALODES,* to which we devote another article, and the pretty *O. verna* was once known as *Cynoglossum Omphalodes,* hence the general style of the several species may be gathered. *C. Wallichii* may be used in several forms of garden decoration, such as the formation of an edging to beds, for carpeting the ground under larger subjects, or for providing little groups in the rock garden. It is a pretty, blue, July flowering plant, growing about 9 ins. high. Seeds are best sown in the flowering positions, and sowing may be done either in September or March in comparatively poor soil. The flowers are freely borne, and are very like those of the Forget-me-not.

Other species sometimes described as annuals really belong to other genera. The biennial, perennial, and greenhouse species of the genus are outside the scope of the present work.

CYNOSURUS (DOG'S-TAIL GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy grasses of little garden value. *C. echinatus* is the COCK'S-COMB GRASS grown sometimes in the wild garden, and averaging about 2 ft. in height. Some of the dwarfer species are used in lawn mixtures.

CYPERORCHIS.—See *ORCHIDS.*

CYPERUS (Nat. Ord. Cyperaceæ). This is a genus of sedges or grasses of no special garden value. *C. longus,* known as GALINGALE, and *C. rotundus,* the NUT GRASS, can both be grown in the damper portions of the wild garden, or in the water garden. They bloom in July, and grow 3 ft. and 1 ft. in height.

CYPRESS.—A name applied to the genus CUPRESSUS. See *TREES.*

CYPRESS OAK (*Quercus pedunculata fastigiata*).—See *TREES.*

CYPRESS SPURGE (*Euphorbia Cyparissias*).—See *EUPHORBIA*.

CYPRESS VINE (*Ipomoea quamoclit*). See *CLIMBING AND TRAILING PLANTS*.

CYPRIPEDIUM (LADY'S SLIPPER. Nat. Ord. Orchidaceæ). — This beautiful hardy plant is suitable for the shady part of the rock garden, and is propagated by division of the crowns in the autumn or spring.

What to Grow.—We briefly describe the best sorts below :—

Cypripedium Calceolus.—A tufted plant with broad leaves on stout stems. Flowers, sepals, and petals brown; lip yellow. Site shade. Soil calcareous rocky loam. Flowering Period, May to June. Height 1½ ft.

C. californicum.—This too is tufted. Flowers, sepals, and petals tawny-yellow; lip blush-white, spotted brown. Site shade. Soil moist, peaty. Flowering Period, May to June. Height, 1½ ft.

C. humile (Syn. *C. acaule*).—This has no stems. Leaves in pairs, broad. Flowers, sepals, and petals greenish; lip rosy-purple. Site shade. Soil moist, peaty, leafy. Flowering Period, May to June. Height, 6 ins.

C. macranthum.—A strong growing plant with tufted stems. Flowers, sepals, petals, and lip deep purple-rose, and large. Site half-shade. Soil sandy loam and limestone. Flowering Period, May to June. Height, 1 ft.

C. macranthum album.—A variety with pure white flowers.

C. montanum.—A distinct and desirable plant. Flowers, sepals, and petals brownish-purple; lip white-striped, red inside, and 3–4 on a stem. Site shade. Soil moist sandy peat. Flowering Period, May to June. Height, 1 ft.

C. pubescens (Syn. *C. hirsutum*).—A free-growing species. Flowers, sepals, and petals yellowish-brown; lip pale yellow. Site shade. Soil moist sandy peat. Flowering Period, May to June. Height, 1½ ft.

C. spectabile (Syn. *C. Reginae*).—The finest species of all. Flowers several on a stem, sepals and petals white; lip rose colour. Site half-shade. Soil well-drained heavy loam. Flowering Period, June to July. Height, 2 ft.

C. ventricosum.—A hybrid between *C. macranthum* and *C. Calceolus*, and intermediate in character.

W. I.

See also *HARDY ORCHIDS* and *ORCHIDS*.

CYRTOMIUM.—See *Aspidium falcatum* in *FERNS AND FERN GARDENING*.

CYRTOPHLEBIUM.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

CYRTOPODIUM.—See *ORCHIDS*.

CYSTOPTERIS.—For the best species and varieties, see *FERNS AND FERN GARDENING*.

CYTISUS.—For the best species see *SHRUBS*.

CZACKIA.—Now included in the genus PARADISEA.

DABOËCIA.—See *HEATHS* and *SHRUBS.*

DACTYLICAPNOS.—Now included in the genus *DICENTRA.*

DACTYLIS (COCK'S-FOOT GRASS. Nat. Ord. Gramineæ).—This is a genus of hardy grasses of very easy culture. They are not of any great garden value, but of weedy habit, and thus we do not propose describing species here.

DACTYLOCTENIUM.—Now included in the genus *ELEUSINE.*

DACTYLOPIUS.—See MEALY BUGS in *INSECT PESTS.*

DADDY LONG-LEGS.—See under LEATHER JACKETS in *INSECT PESTS.*

DAFFODIL ANEMONE (*Anemone narcissiflora*).—See *ANEMONE: ROCK GARDEN SPECIES.*

DAFFODIL GARLIC (*Allium neapolitanum*).—See *ALLIUM.*

DAFFODILS (Nat. Ord. Amaryllidaceæ).—**History.**—British gardens have had Daffodils in them for hundreds of years; but within the last quarter of a century they have risen to a prominence which has been most marked. There is hardly a garden of any size without its Daffodils, and shows for Daffodils have been established in various centres. In New Zealand they are even more a feature of spring shows than in the old country. About the end of the eighteenth, and in the early half of the nineteenth centuries, it was the Polyanthes or bunch-flowered varieties that alone were considered worthy of notice, but the one-flowered hold the pride of place to-day. The change has been brought about by the work of Herbert, Dean of Manchester, Backhouse of York, Leeds of Manchester, Barr of London, and more especially Engleheart of Dinton, the most famous raiser of new varieties who has ever lived. The modern developments of the flower are simply surprising. For convenience of reference the family has been divided into sections by the Daffodil Committee of the Royal Horticultural Society.

Classification: *R.H.S. Classified List of Daffodils.*—This list is most useful. All the schedules of Daffodil shows are more or less arranged according to its provisions, and in bulb dealers' catalogues the Daffodil part usually follows its main outlines. The divisions are based on (1) colour, (2) blood relationship, and (3) the general shape of the bloom, which depends on the proportions which the central part of the flower, or the corona, bears to the petals, or to write more strictly botanically, the perianth segments. (When the parts of the calyx and corolla are like one another, as in the Narcissus or Daffodil family, they are usually spoken of as a *Perianth.*)

The following are the divisions:—

(*a*) TRUMPET DAFFODILS.—The trumpet or corona is as long as or longer than the perianth segments. The sub-divisions depend on colour; *e.g.* (1) Yellow, (2) White, (3) Bicolor.

(*b*) INCOMPARABILIS.—The cup or corona must be not less than one-third, but less than equal to the length of the perianth segments. The sub-divisions depend on the colour of the perianth; (1) Yellow perianths, (2) White perianths.

(*c*) BARRII.—The cup or corona must be less than one-third the length of the perianth segments. The sub-divisions depend on the colour of the perianth; (1) Yellow perianths, (2) White perianths.

(*d*) LEEDSII.—The perianths must be white, with white, cream, or pale citron cups, which are sometimes tinged with pink or apricot. The sub-divisions depend upon size; *e.g.* (1) Flowers of Incomparabilis proportions, (2) Flowers of Barrii proportions.

(*e*) TRIANDRUS HYBRIDS.—All varieties which obviously contain triandrus blood, such as *Queen of Spain* (yellow), and *Venetia* (white).

(*f*) CYCLAMINEUS HYBRIDS.—Flowers with cyclamineus as one of the parents.

(*g*) JONQUILLA HYBRIDS.—Varieties of *Narcissus Jonquilla* parentage, such as *Buttercup, Odorus*, etc. etc. Jonquil blood gives richness and smoothness of texture.

(*h*) TAZETTA AND TAZETTA HYBRIDS.—These are the POLYANTHES NARCISSUS of gardens. The new poetaz (hybrids between a poet and a bunch-flowered or tazetta variety) are also included.

(*i*) POETICUS VARIETIES.—All poets have pure solid white petals with a small eye, wholly or partly red.

(*j*) DOUBLE VARIETIES.

(*k*) VARIOUS.—This is an omnibus division, and includes certain species such as *N. Bulbocodium, N. cyclamineus, N. gracilis, N. triandrus, N. Jonquilla, N. juncifolius, N. viridiflorus*, etc. etc.

NAME OF FAMILY.—All Daffodils are Narcissi, and all Narcissi are Daffodils; Daffodil being the English and Narcissus the Latin name of the family. It is custom alone that limits the name Narcissus to the Poeticus and Tazetta sections. Parkinson in his *Paradisus* (1629) has some interesting remarks on nomenclature.

Border Cultivation.—Daffodils like a warm well-drained soil, and a moist atmosphere. The Poeticus section, however, prefers a fairly stiff rooting medium.

Plant as early as possible in the autumn, and beware of planting after Lord Mayor's Day. Never cut off the foliage while it is green; the bulbs may stand it once but not a second time. With few exceptions all varieties may remain in the ground for several years, but they should be top-dressed annually with good soil mixed with bone-meal and *old* farmyard manure. These also are the best and safest manures to dig into the beds before planting.

All Daffodils do well in grass; in fact, certain sorts will not thrive anywhere else. Wait until the autumn rains have moistened the ground before planting. Avoid mixtures; much the best and most pleasing results are obtained when the varieties are kept distinct. One of the best examples of grass planting is to be seen at Glasnevin Gardens, Dublin. Even when the area to be covered is a large one, a Barr's Bulb Planter should be used. A general mistake is to plant too close together; with this tool it is hardly possible to do so. Never mow grass where Daffodils are until their foliage has become yellow.

Pot Cultivation.—Plant all varieties as early as possible in September, or the first two weeks in October. Where the bulbs have to live in a dwelling-house all the time, the middle of October is soon enough. Before bringing any pots into heat, be sure that they are filled with roots.

Enemies and Diseases.—The chief living enemies are the Merodon or large Daffodil fly; the Eumerus or small Daffodil fly, and the eelworm or *Tylencus devastatrix*. The chief disease is that caused by a Fusarium fungus. Slugs can also do much damage by eating off the roots. Whenever the foliage becomes curled and marked with brown stripes, expert advice should be obtained.

Raising Seedlings.—Seed should be sown very thinly in August in boxes or pans. These will be all the better for the protection of a cold airy frame. Allow the seedlings to remain two years in the seed boxes before planting out in nursery beds. Once planted out they may remain where they are until they bloom. Flowers may be expected in the fifth year; but a few will flower in the fourth year, and some not until the sixth or seventh.

Varieties for Garden Purposes.—Good garden varieties include the following, the letters which follow the names indicating the divisions to which they belong:—Argent (*j*); Barrii conspicuus (*c*); Bernardino (*b*); Blackwell (*b*); Cassandra (*i*); Duke of Bedford (*a*); Elvira (*h*); Emperor (*a*); Empress (*a*); Evangeline (*d*); Horace (*i*); J. T. Bennett-Poë (*e*); Lady Margaret Boscawen (*b*); Madame de Graaff (*a*); Norah Pearson (*d*); Odorus Campanelle (*g*); Pedestal (*b*); Philippe de Vilmorin (*a*); Poeticus recurvus (*i*); Seagull (*c*); Sir Watkin (*b*); Vestal Virgin (*a*); Virgil (*i*); White Lady (*d*).

The following are recommended for pot culture, the letters which follow the names again indicating the divisions to which they belong:—Argent (*j*); Aspania (*h*); Bedouin (*b*); Blackwell (*b*); Bulbocodium conspicuus (*k*); Cornelia (*a*); Diana (*d*); Emperor (*a*); Evangeline (*d*); Firebrand (*c*); Golden Spur (*a*); Henry Irving (*a*); Homer (*i*); Jaune à Merveille (*h*); J. T. Bennett-Poë (*e*); King Alfred (*a*); Lucifer (*b*); Madame de Graaff (*a*); Mrs Langtry (*d*); Princeps (*a*); Sir Watkin (*b*); Sunrise (*c*); Victoria (*a*); Weardale Perfection (*a*).

J. J. & E.

Varieties for Show.—These are improved upon so frequently that our contributors tell us it would be of no practical value to give a selection here. A bulb specialist should be consulted.—EDITOR.

NEW VARIETIES.

Incomparabilis Section: *Fortune.*—This has a yellow perianth and a rich orange-scarlet crown.

Ixion.—This has a lemon-yellow perianth and an orange crown.

Knight Templar.—This has a creamy-white perianth and a red crown.

Phineas.—This has a lemon-yellow perianth and a golden-yellow crown.

Yellow Standard.—This has a citron-yellow perianth and a golden-yellow crown. It is a giant flower.

Leedsii Section: *Miss E. M. Bowling.*—This has a creamy-white perianth, and half its trumpet is cream with a pink rim.

Poeticus Section: *Bridget.*—This has a white perianth and a rich red and green cup.

Cædmon.—This has a white perianth, and its cup is margined with dark red.

Crimson Braid.—This has a pure white perianth, a scarlet cup, and a yellow centre.

Thoroughbred.—This has a white perianth and a cup rimmed with crimson.

Trumpet Section: *Fides.*—This has a white perianth and a yellow trumpet.

General Bland.—This is a giant yellow variety, often 5½ ins. across the perianth.

General Townsend.—This is a pure yellow variety.

Tamora.—This has a snow-white perianth and a creamy-white trumpet.—W. J. C.

[It should be noted that the above is only a selection of those which have received official recognition. The list might be considerably extended.—EDITOR.]

DAGGER FLOWER (*Aster tanacetifolius*).—See *ASTER*.

DAHLIA : Culture of.

The cultivation of the Dahlia may be divided into two clearly defined sections, namely, for exhibition and for garden decoration. Few species of flowers are so well adapted for either purpose, as if grown for decoration the culture is simple, and the return in quantity of bloom is great, extending over a long period; while as an exhibition subject, especially for the man of small means, the Dahlia is second to none. An exhibition flower to be really popular, must require some considerable skill in order to perfect it, and a Dahlia needs just the care and attention, sufficient to impart zest to the competitor, without the need of any elaborate appliances or even a greenhouse or frame.

Culture for Exhibition.—Taking this first, it is safe to say that overmanuring is not a common occurrence, as a rich soil is the first essential.

We will deal with the routine work as regards the production of the finest Cactus Dahlias. This will perhaps give the best idea of what is suitable for all sections, with a few slight modifications of course.

Young plants from cuttings should be obtained in April, potted into 5-inch pots, and grown on till sturdy and well rooted. If no greenhouse or frame is available delay purchasing till May.

The land should be well manured, and deeply dug. It must be in a friable condition at planting time, which is about the 21st of May.

When planting, place the ball of soil from pots 2 ins. below the level of the ground, and tread the fresh soil gently but fairly firm round it. Put to each plant a stake at least 4½ ft. high, when fixed, and tie at once.

If the weather is dry, water once thoroughly, and spray overhead each evening, repeating the watering in a week's time.

As soon as the plants have become established and grown to 15 ins. in height, which will be by end of June, cut out the tips. From the side shoots which now break forth at each joint, select six or eight and allow these to grow and eventually flower.

By early July two additional stakes should be put to each plant, and rough string known as fillis run round the three stakes, just high enough for the young growths to reach, when each should be loosely secured with raffia.

As the shoots grow add another string, and so on till the plant in August presents a trim, well-kept appearance. It will be quite secure from wind.

Now comes the question of thinning, and feeding. If the largest flowers are looked for, only the central bud on each main shoot should be left, and the side growths down to three joints removed as well. Some varieties will also require a few big leaves cut off, and it is always safe to cut out all weakly shoots.

By early August feeding should commence. In dry seasons put some fresh cow or sheep manure in a tub or tank full of water, adding a bag of soot, and brew a strong dark-coloured mixture. To each plant give two gallons as often as water is needed, say twice a week. In wet weather the best way to feed is to sprinkle artificial manure and soot round the plants and let it wash in. The artificial may also be used when watering, and the Dahlia is not fastidious in its choice of proprietary fertilisers.

The old Double or Show Dahlia may be treated much in the same way, and if large flowers are wanted,

the Paeony sorts may also have similar treatment.

One or two other sections are definite exhibition favourites, namely the little Pompon and the Singles; both of these are judged more from the standpoint of neatness than size, and to show big Pompons would be useless.

They should be grown well as regards the actual culture, but not disbudded. A large bushy plant freely covered with flowers is necessary when perfect blooms are wanted.

Culture for Garden Purposes.—Taking the Dahlia as a garden plant, our task is simplified, as quantity, rather than quality, is the object in view.

All sections are suitable for the purpose, although in the case of the Cactus it is necessary to ensure getting varieties with stiff stems. As in the case of exhibition plants, the soil should be well worked and manured, but less thinning and disbudding, or indeed none at all in the case of most varieties, is needed.

Dahlia Sections and Varieties.[1]—A brief description of the chief sections of the Dahlia family may be of use to beginners.

The CACTUS DAHLIAS are those with long narrow florets full to the centre, some forms being perfectly incurved, and others star-like. A dozen good exhibition sorts are :—

Alabaster (white).
A. R. Perry (rose and yellow).
F. W. Fellowes (orange, scarlet).
F. Wenham (fawn pink).
Guardian (crimson scarlet).
Miss Stredwick (yellow to pink).
Mrs. M. Stredwick (clear pink).
Patriot (scarlet).
Planet (white, speckled crimson).
Sussex (yellow).
Vulcan (maroon).
Washington (crimson).

We now come to the COLLERETTES, the daintiest of all the family. These have eight petals as in Single Dahlias, but each main petal has a tuft or collar of secondary florets, usually of contrasting colour. They are unequalled for all decorative purposes, and last well when cut and placed in water.

Many varieties are very similar, but a few distinct sorts include the following :—

Flame (vivid flame).
Garland (scarlet).
H. Farman (yellow, suffused red).
Hornet (crimson).
Louie Blackman (magenta).
Medallion (yellow).
Mizar (white, striped scarlet).
Nightingale (orange and yellow).
Queen Mary (rose pink).
Regularity (purple).
Rifleman (velvety maroon).
Swallow (white).

A striking class of Dahlias are known as DECORATIVES, and embrace many nondescript forms. Those termed "giant" are large, often huge, and have broad flat florets full to the centre. They are easy to grow, and have no special "show" points.

Twelve representative sorts should include :—

Brentwood Yellow (yellow).
Delice (rose pink).
Futurity (salmon buff).
Leviathan (crimson).
Mabel (mauve).
Madame Gustave Douzon (scarlet).
Mastiff (yellow to bronze).
Seahorse (yellow, tipped white).
Startler (cardinal, *i.e.* deep scarlet).
Sulphurea (sulphur yellow).
Warneford (white).
Wyvern (lilac).

[1] Dahlia Varieties change frequently, as do varieties of many florists' flowers. Thus what may now be a first-class sort may in a few years' time be the poorest variety of all. On the other hand it may not. Readers who wish to know the latest improvements should consult specialists in the trade, or the National Dahlia Society which exists for the furtherance of this flower's popula ' ty.

DOUBLE OR SHOW DAHLIAS are the round ear-wiggy old-fashioned ones, and are perhaps, in their perfectly symmetrical outline, the greatest triumph of the florist's art.

Twelve of the best are :—

A. M. Burnie (orange).
Arthur Rawlings (crimson).
Chieftain (purplish lilac).
Colonist (chocolate and fawn).
Gracchus (orange buff).
John Walker (white).
J. T. West (yellow, tipped purple).
Mrs. Gladstone (pink).
Perfection (buff).
R. T. Rawlings (purple).
Tom Jones (cream, edged mauve).
William Rawlings (purple).

The Dahlias known as PAEONY-FLOWERED are semi-double, with flattish florets more or less irregular and informal. They are suitable for masses of colour in the flower border.

A useful dozen are :—

Amber Queen (amber).
Geisha (scarlet and yellow).
Holman Hunt (crimson).
Liberty (scarlet).
Luna (yellow).
Naomi (deep rose).
Phideas (salmon pink).
Samson (cardinal).
Sheila (pink).
Titian (petunia colour).
Wedding Day (red, tipped white).
White Flag (white).

POMPON DAHLIAS are the tiny round varieties. They should be grown in every garden, as they flower freely and are bright and effective.

Some good sorts include :—

Adelaide (blush).
Bacchus (red).
Barbara Purvis (white).
Darkest of All.
Emily Hopper (yellow).
Geo. Ireland (heliotrope).
Glow (coral).
Johnny (maroon).
Neatness (salmon buff).
Nerissa (pink).
Rosa (blush white).
Tommy Keith (red, tipped white).

Secrets of Success.—These are four in number. Dig deep ; manure well ; plant good sorts ; and, above all, securely stake and tie the shoots against damage by wind.—H. S.

NEW VARIETIES.

The following are some of the best out of a large number of novelties :—

CACTUS.—The height of these, unless otherwise stated, is 4–5 ft.

Bizarre.—Scarlet and white flowers.

Crescent.—Yellow and pink flowers.

Curlew.—Old rose flowers.

Erin.—Deep orange flowers. Height, 2½ ft.

Etoile Rose.—Pink flowers, with a white centre.

Geraldine Edwards.—Lavender blush flowers.

Lieut. Robinson, V.C.—Ruby-coloured flowers.

Marion Walton.—Pink flowers.

Meridian.—Pale yellow flowers.

Mrs D. B. Crane.—Pure white flowers.

Pennant.—Coral flowers.

Royal Sussex.—Glowing red flowers shaded with orange.

Saffron.—Pure saffron-yellow flowers.

Sir D. Haig.—Soft pink and white flowers.

The Guardian.—Scarlet flowers.

The Swan.—Pure white flowers.

Ursa Major.—Yellow and scarlet flowers.

W. E. Peters.—Crimson-scarlet flowers.

COLLERETTE.—The usual height of these is 3½–4 ft.

Autocrat.—Orange scarlet flowers tipped with yellow, and with yellow collerette.

Autumn Tints.—Reddish orange flowers, with yellow collerette.

Bonfire.—Bright orange-scarlet flowers.

Bullfinch.—Crimson-scarlet flowers, with yellow collerette.

Canopus.—Pale yellow flowers, with white collerette.

Carron.—Scarlet flowers tipped with yellow, and with light yellow collerette.

Cupid.—Purple flowers on a white ground, and with a white collerette.

Deveron.—Rosy-cerise flowers, with white collerette tinted red.

Don Juan.—Scarlet flowers, with yellow collerette striped red.

Eclipse.—Crimson flowers tipped with yellow, with pale yellow collerette.

FireKing.—Orange-scarlet flowers, with yellow collerette marked with scarlet.

Gipsy.—Purple and maroon flowers, with white and purple collerette.

Kangaroo.—Maroon flowers, with white and crimson collerette.

Lynx.—Orange-scarlet flowers tipped with yellow, with yellow collerette.

Matilda.—Pale yellow flowers with purple patch, and yellowish-white collerette.

Mrs J. A. Jarrett.—Crimson flowers tipped with white, with white collerette.

Péronne.—Scarlet flowers, with yellow collerette striped red.

Star of Mons.—Crimson flowers tipped with yellow, with yellow collerette.

W. Dunns.—Bright crimson flowers, with lemon and crimson collerette.

Yellow Queen.—Yellow flowers, with collerette of the same colour.

DECORATIVES.—The usual height of these is 3½–4½ ft.

Adallus.—Crimson flowers, with lilac reverse.

Bianca.—Pure white flowers.

Blaze.—Brilliant scarlet flowers.

Cambria.—White centred flowers shading to rose on outer petals.

Cassiope.—White flowers, with crimson margins and yellow centre.

Clematis.—Pale rosy-mauve flowers shaped like a clematis.

Crimson Flag.—Fiery crimson flowers.

General Joffre.—Deep crimson flowers.

Lodestar.—Yellow flowers, paler on the outside.

Miss Irwin.—Rosy-carmine flowers.

President Wilson.—Orange-scarlet flowers.

Profusion.—Rose flowers tipped with yellow.

Queenie.—Yellow flowers flushed with apricot.

Robin.—Rich rose flowers.

PAEONY-FLOWERED.—The usual height of these is 3½–4 ft.

Alma.—White flowers, with orange centre.

Anerley Yellow.—Clear yellow flowers.

Iliad.—Salmon-pink flowers on cream base, with yellow band along the centre.

J. A. Jarrett.—Yellow flowers tipped with scarlet.

Mark.—Orange-scarlet flowers, with orange centre.

Pink Apollo.—Rosy-pink flowers.

Rev. John Hamlet.—Rosy-cerise flowers, with orange centre.

St Egwyn.—Bright rose flowers, paler at the edges.

Sonata.—Purple-maroon flowers.

POMPONS.—The usual height of these is 3–4 ft.

Amethyst (CACTUS).—Deep amethyst flowers.

Janus.—Maroon flowers.

Raider.—Primrose-yellow flowers.

Rotifer (CACTUS).—Rosy-red flowers tipped with white.

Speedwell (CACTUS).—Pure white flowers.

Vanessa.—Snow-white flowers.

SINGLES.—The usual height of these is 3–4 ft.

Diamond.—Maroon-crimson decorative flowers.

Eileen.—Deep rose flowers tipped with white, and with yellow ring round centre.

Lemur.—Rich scarlet-crimson flowers.

Margery Choune.—Deep crimson decorative flowers, with a yellow base.

Pastel.—Pink and crimson flowers; a giant decorative.

Penelope.—Deep rosy-mauve and white flowers.

Sapho.—Bronzy-yellow decorative flowers, tipped with pale pink.

Tipperary.—Scarlet-crimson decorative flowers tipped with white.

White Tip.—Deep crimson flowers, tipped with white.

STAR or COSMEA-FLOWERED.—The usual height of these is 3½–4 ft., and all have yellow discs.

Autumn Star.—Terra-cotta flowers flushed with red.

Coral Star.—Coral red flowers, with the petals quilled like a cactus variety.

Mauve Star.—Rosy-mauve flowers.

Moonstar.—White flowers, with purple base.

Nanette.—White flowers, with yellow edge.

Oriole.—Bright scarlet flowers.

Sussex Star.—Warm pink flowers, with yellow base.

White Star.—White flowers.

Worth Star.—Old rose flowers, with white bars down the middle of the petals.

Yellow Star.—Yellow flowers.

W. J. C.

[**Storing Dahlias.**—Just a word about the storing of Dahlia roots after the flowering season is over. They are not sufficiently hardy to be left out of doors in the open ground unprotected. We find it is best to lift them in late October or early November and store them in a dry frost-proof shed, though not necessarily in darkness, after cutting off the top-growth to within 9 ins. of the roots. In April these roots are brought out, some of the bigger tubers being cut off, and the roots split up so as to obtain a strong "crown" so to speak. The roots are then started in a greenhouse or on a hotbed, duly hardened off and planted out in exactly the same manner as our contributor recommends for cuttings.—EDITOR.]

DAHLIA : Historical Notes.

The Dahlia has been grown in Europe since 1789, in which year Cervantes of the Mexico Botanic Garden sent three varieties to the Abbé Cavanilles of Madrid. It was then a new and unknown plant, and after it had been flowered in the Madrid Botanic Garden, Cavanilles named it *Dahlia* out of respect for the great Swedish botanist André Dahl.

These varieties were figured and described by Cavanilles in his "*Icones*"; they were called *Dahlia pinnata*, *D. rosea*, and *D. coccinea*, all large, broad, flat-petalled, single-flowering varieties.

Some confusion was caused in the early days of the flower's history by Willdenow of Berlin giving the plant another name, that of *Georgina*, but ultimately on the score of priority, English, French, and other botanists, except the Germans, decided to revert to the original name, and by them Dahlia has ever since continued to be used.

It has been erroneously stated by every writer on Dahlia history for upwards of a century that this flower was originally introduced into England in 1789, but this is an error which has been fully exposed by the present writer in a paper entitled "The Dahlia, its reputed introduction in 1789," which appeared in the Journal of the R.H.S. (see Parts II. and III., vol. xlii.). It is there shown beyond question

that it was not till 1798 that the plant, through the instrumentality of Lady Bute, reached this country, and that it was grown at Kew for a few years and then disappeared.

The credit of its second introduction into England is due to Lady Holland, who in 1804 sent seeds home from Spain. Since that time its cultivation has been continuous ; the flower was taken in hand by skilful florists, and was soon improved in form, size, and colour. It was therefore not long before it took rank as an exhibition flower, and many and frequent were the shows organised to encourage its culture.

The great object in view in its early days was to get the flower to double. This was a slow and gradual process, as can be seen by reference to the numerous publications in which the Dahlia was represented and referred to. But the florists' desire was ultimately accomplished, and the result was that type known as the old show and fancy varieties : big, solid, globular flowers which were once the pride of the dahlia fancy, but which have now been somewhat eclipsed by the less formal-looking novelties of later years.

In 1802 it was introduced into France. André Thouin figured and described it in 1804. De Candolle six years later also wrote about it. It soon became widely grown in France, the Comte Lelieur and many other seedling raisers doing excellent work in elevating the flower to a higher standard of perfection. About the same time the German horticulturists received plants, and their efforts in seeding and improving the flower resulted in great changes in it. Hartweg, Otto, Fintelmann, Deegen, and others are worthy of mention in respect of the popularity of the flower gained in their country.

For many years, whatever may be said to the contrary, Dahlias were confined to that type known as the old show and fancy varieties, and no break was made until the year 1850. In that year Sieckmann of Köstriz obtained and put into commerce the first pompon dahlia, thus creating a new departure ; this little floral gem was variously denominated lilliputian, bouquet, but more recently pompon.

The Cactus type also came originally from Mexico, and was the precursor of the new race of decorative and exhibition flowers now so highly esteemed. Like the more recently introduced paeony type the cactus dahlia reached us through Holland, where it had been grown some few years prior to its introduction here.

The Collerette section was another peculiar departure from the normal, the first example of these being raised at Lyons, in France, in the year 1899. The singles, the decoratives, and one or two other sections all tend to prove how variable this New World plant has been. Its history and literature are very extensive, and necessitate a knowledge of English, French, and German to enable the student to dive deeply into the records, for in the early days it was a flower of European reputation, and justice cannot be done to the subject in a few paragraphs.

To encourage its culture the National Dahlia Society was founded many years ago, and still continues its good work holding its exhibitions, publishing its catalogues and other literature with almost unfailing regularity.

In America remarkable progress has been made in dahlia cultivation ; it is rapidly extending over the Union, and there is no doubt that the formation of the American Dahlia Society will do much to help

its members and the general public to become acquainted with the beauty and the usefulness in so many ways of this very gorgeous autumn flower.—C. H. P.

DAHLIAS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING.*

DAINTY BOLET.—See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

DAISY (*Bellis*. Nat. Ord. Compositæ).—The daisies, so well known as dwarf-growing, hardy herbaceous perennials, cannot be said to be amongst the best flowers in cultivation, but most people are too fond of them to overlook them. The sight of a good patch of these bordering a perennial parterre will often bring back happy memories of childhood's days and the daisy chains made in them long ago. Certainly the plants are very easy to grow; most species come very freely from summer-sown seed in the usual way, and all are freely propagated by division either immediately after flowering or in the autumn and spring. *B. perennis* is often used for winter or spring bedding, and is then treated as a hardy biennial; or stock may be obtained by dividing established plants in July, growing them on in the reserve garden, and planting out in October. We recommend the following three species:—

Bellis perennis.—This, the best known daisy of all, is available in red, rosy-pink, cream, and white. The best varieties of it are *hortensis* and *tubulosa*. Both are double red; both bloom freely in June, and both average 3–6 ins. in height. The type is a weed, and as such is described in our article on *WEEDS*.

B. rotundifolia.—This is a white species, but its other characteristics are similar to *B. perennis*.

B. sylvestris.—This bears white flowers from June onwards, and averages 6–12 ins. in height.

[A number of other daisies distinct from Bellis will be found dealt with in different articles.—EDITOR.]

See also *WEEDS*.

DAISY BUSH.—The genus OLEARIA. See *SHRUBS*.

DAISY GRUBBERS.—See *GARDEN TOOLS*.

DAMASK ROSE (*Rosa damascena*).—See *ROSE SPECIES*. For the best varieties see *ROSE CLASSES*.

DAME'S VIOLET.—See *ROCKET*.

DAMP-HATING ROCK PLANTS.—See ROCK PLANTS DISLIKING DAMP in *ROCK PLANTS FOR ALL PURPOSES*.

DAMPING DOWN.

Most greenhouse plants benefit by this in the summer, and hothouse plants benefit by it throughout the year. The staging and floor of greenhouses, and the foliage of plants themselves, is easily damped down by means of a fine-rosed watering-can. For the roof and walls, also for tall climbers, etc., a syringe has to be employed. Damping down cannot be overdone in the summer, but in the winter it should be done with the greatest caution when necessary, as otherwise it may do more harm than good.

DAMPING OFF.—See *DISEASES OF PLANTS*.

DAMSONS AND BULLACES.

These are useful as wind-breaks, and do not take much room in the garden. If grown as standards they give very little shade. Their culture is easy, and good results will follow if the general hints on hardy fruit culture are adopted.

SELECTION OF SORTS.

Bradley's King.—Oval, very prolific. Sweet and delicious.

Shepherd's Bullace.—Green and yellow. Useful in November.

The Cheshire Prune (weeping variety).—Large, bears freely some years. Ready in October and November.

The Damascene of Worcester.—Large, very rich cooked. Good bearer.

The Mereweather.—Very fine. As large as *Prolific Plum.* Late, with rich Damson flavour—extra good.

Veitch's Black Bullace.—Great bearer. Ready end of October.

G. B.

DANDELION.—See *MEDICINAL HERBS, SALAD PLANTS,* and *WEEDS.*

DAPHNE (GARLAND FLOWER. Nat. Ord. Thymelaeaceæ).—A genus of dwarf shrubby rock plants, bearing sweetly scented waxlike flowers. They are propagated by cuttings in July, or by grafting, and all require well-drained gritty loam and peat, except one or two lime lovers.

Rock Garden Species.—The best are briefly described below :—

Daphne alpina.—A small bush with white flowers. Site sunny. Soil gritty loam and peat. Flowering Period, May to June. Height, 1–2 ft.

D. blagayana.—A prostrate shrub with large white flowers. Site half-shade. Soil, peat and loam, stony. Flowering Period, May to June. Height, 1 ft.

D. Cneorum.—An evergreen trailing shrub with rosy-pink flowers. Site half-shady. Soil, peat and loam. Flowering Period, May to June. Height, 1 ft. The variety *alba* has white flowers.

D. petraea (Syn. *D. rupestris*).—A dwarf shrub with pink flowers. Site half-shade. Soil, calcareous loam, rocky. Flowering Period, May to June. Height, 4 ins.

W. I.

NEW VARIETIES.

Daphne Cneorum Veiloti.—This has sweetly scented, deep rose flowers, on leafy branches, but not so dense as the type.

D. petraea grandiflora.—This bears large pink flowers. It is a very dwarf subject, only 2 ins. high.

See also *SHRUBS.*

DAPHNIPHYLLUM.—For the best species see *SHRUBS.*

DAREA.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

DARI.—See *SORGHUM.*

DARNEL (*Lolium temulentum*).—See *LOLIUM.*

DARWIN TULIPS.—See under VARIETIES in *TULIPS.*

DATE PALM (*Phoenix dactylifera*).—See *PALMS.*

DATE PLUM.—The genus DIOSPYROS and *D. Kali.* See *TREES.*

DATURA[1] (Syn. *Brugmansia.* Nat. Ord. Solanaceæ).—This is a genus of greenhouse shrubs and annuals. The shrubby species attain a height of 10–12 ft., and the annuals about 2 ft. Turfy loam, with a liberal addition of well-decayed manure and some sharp sand, is a suitable compost. Propagation is best effected by cuttings for the shrubby species, and by seed for the annuals.

Culture.—Cuttings, about 6 ins. long, taken with a heel, will root readily in light soil if given gentle bottom heat. Seeds sown in heat in the spring soon germinate. The young plants should be hardened off, and may be planted out when all danger of frost is over.

USES.—The shrubby species are only suitable for large greenhouses, as the branches spread widely. Established plants are, however, extremely handsome when in bloom during July and August, and the flowers are sweetly scented. When grown in pots or tubs, they may be placed out of doors during the summer months. Winter treatment is the same as that given to the *FUCHSIA,* which see. The annuals

[1] A popular name for Datura is THORN APPLE.—EDITOR.

may be grown and used in the same way as any other greenhouse plant.

Varieties.—*Datura suaveolens*, and its garden form *Knightii*, are the best known and most useful. These, and *Arborea*, have white flowers. *D. chlorantha*, a May flowering species, is yellow, and *D. sanguinea* bears scarlet blooms in August. The two last are not often grown now.

J. L. G.

See also THORN APPLE in *MEDICINAL HERBS*.

DAUCUS (Nat. Ord. Umbelliferæ). A large number of annual and biennial species of this genus have been described, and some of them are offered at times in catalogues to the unwary amateur. All the species save one are far too weedy to be worthy of a place amongst one's flowers. The one exception, which has in the past War years been seen in flower borders with some success (especially as an edging) is *D. carota*, the common CARROT of the kitchen garden, the culture of which is fully described in our article on *CARROTS*.

DAVALLIA.—For the best species and varieties see *FERNS AND FERN GARDENING*.

DAVID'S HARP (*Polygonatum multiflorum*).—See *SOLOMON'S SEAL* and *WATER GARDEN: PLANTS FOR THE* (in the last article see under SOLOMON'S SEAL).

DAY FLOWER.—See *COMMELINA*.

DAY LILY (*Hemerocallis*).—See *HEMEROCALLIS* and *WATER GARDEN: PLANTS FOR THE*.

DEADLY NIGHTSHADE.—A synonym for BELLADONNA, which see in *MEDICINAL HERBS*.

DEADLY NIGHTSHADE (*Atropa Belladonna*).—See *ATROPA*, and under BELLADONNA in *MEDICINAL HERBS*.

DEADNETTLE.—See under RED DEADNETTLE in *WEEDS*. See also *LAMIUM*.

DEATH CAP.—See ARCH-BANE under HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

DECIDUOUS CEDAR.—See the genus TAXODIUM in *TREES*.

DECIDUOUS CYPRESS (*Taxodium distichum*).—See *TREES*.

DECIDUOUS SUBJECTS.—See *GARDEN FENCES*.

DECORATIVE DAHLIAS.—See DAHLIA SECTIONS AND VARIETIES in *DAHLIA: CULTURE OF*.

DECORATIVE HEDGES.—See *GARDEN HEDGES*.

DEER GRASS (*Rhexia virginica*. Nat. Ord. Melastomaceæ).—This pretty little hardy perennial, bearing purple flowers about July, is not as much grown as it might be. It is of very easy culture in light loam, peat, and sand, and may be propagated in the usual way by root division in the spring. The height rarely exceeds 9 ins.

DEERBERRY (*Vaccinium stamineum*). See *SHRUBS*.

DELPHINIUM, ANNUAL.—See *LARKSPUR*.

DELPHINIUM [1] (Nat. Ord. Ranunculaceæ). — Hardy herbaceous perennials, 3–8 ft. high, succeeding in ordinary garden soil well worked and liberally manured. They are propagated by seed sown in spring, in which case the plants should bloom in fifteen months or so after germination. They are also increased by division of roots in the autumn or spring. Seedlings from a good strain of seed will give flowers of excellent quality, but if the named varieties are wanted plants must be procured.

Cultural Notes.—Growing as they do to a height of 6 ft. or more, Delphiniums are almost unsurpassed for stately effect in the flower borders. In good soil the plants should be placed at least 3 ft. apart, clumps of five or seven

[1] Delphiniums are also known as LARKSPURS, although this name now is more or less limited to the annual species and varieties. For these last see article on *LARKSPUR*.—EDITOR.

togethe rgiving a good effect. In shallow or poor soil, manure must be liberally incorporated, and liquid stimulants given in the growing season. The flower spikes are at their best in June and July, but if these are removed as soon as the blossoms fade, secondary growth will give useful spikes of flowers in September. Slugs are particularly fond of the young growths in spring, and it is well to protect them with frequent dustings of soot, which will act as a manure at the same time.

Varieties.—Capri, Dusky Monarch, Henri Moisson, His Excellency, King of Delphiniums, Masterpiece, Moerheimi (white), Persimmon, Princess Juliana, Rev. E. Lascelles, Statuaire Rude, The Alake.—J. L. G.

DELPHINIUM : Perennial Border Species.—On account of the great number of garden varieties, Delphinium species are not much grown. Most of them are attractive, as well as of very easy culture, and may be grown in the manner already outlined. They are propagated without difficulty by seeds and root division at the usual times. We recommend the following :—

Delphinium altissimum. — This bears blue flowers in July, and grows 6–9 ft. in height.

D. cardinale.—This bears scarlet flowers in August, and grows a yard in height. It is a biennial or short-lived perennial.

D. cashmirianum. — This bears dark blue flowers in July, and grows 1–1½ ft. high. Its variety *album* is white.

D. caucasicum.—This bears violet-blue flowers in July, and grows half a yard in height.

D. crassicaule.—This bears pretty blue flowers in June, and grows 2 ft. high.

D. dyctiocarpum. — This bears blue flowers in July. Height, 4 ft.

D. elatum.—This and its variety *alpinum* both bear blue flowers from July onwards, and average 5–6 ft. high.

D. exaltatum.—This bears blue flowers from July to August, on plants a yard high.

D. formosum.—This bears bright blue flowers from June to August, and grows a yard in height.

D. grandiflorum.—This bears deep blue flowers in July, and grows 1½–2 ft. in height. Its varieties *album* (white), *flore pleno* (double blue), and *rubrum* (red) are also worthy of culture.

D. hybridum.—This bears blue flowers from July onwards, and grows a yard in height.

D. nudicaule.—This bears attractive orange-scarlet flowers from June onwards, and grows about half a yard in height.

D. speciosum.—This bears attractive blue flowers from July onwards, and grows 4–5 ft. in height. Its varieties *glabratum* and *turkestanicum* are also worth including.

D. triste.—This bears blue flowers in June, and grows about half a yard in height.

New Species.

Delphinium tanguticum. — This bears blue and white flowers, and is a dwarf species suitable for rock garden culture, growing 6–8 ins. high.

D. venustum.—This has rich deep blue flowers, with a brown centre and deeply cut leaves.

New Varieties.

The following are some of the best :—

Delphinium Joan.—Intense blue single flowers, and compact habit.

D. Lloyd George.—Dark blue single flowers, with a yellow eye.

D. Mrs A. J. Watson.—Purple

and light blue double flowers, borne on spikes 2–3 ft. long.

D. Mrs Baker.—Light blue and mauve semi-double flowers.

D. Mrs Colin McIver.—Deep mauve-purple double flowers.

D. Mrs H. Kaye.—Dark blue and purple flowers, with a brownish centre.

D. Mrs Shirley.—Mauve flowers in close, narrow spikes.

D. Queen of the Belgians.—Sky-blue semi-double flowers, shaded mauve and with yellow centre, borne on spikes 2 ft. in length.

D. Sir Douglas Haig.—Deep purple and blue double flowers, borne in dense spikes.—W. J. C.

DENDROBIUM.—See *ORCHIDS.*

DENDROCALAMUS.—A species of BAMBOO. See *BAMBOOS.*

DENTARIA.—Now included in the genus *CARDAMINE.*

DEODAR (*Cedrus Deodara*).—See *TREES.*

DEPRESSARIA.—See FLAT BODY MOTHS in *INSECT PESTS.*

DEPTFORD or THRIFT PINK (*Dianthus Armeria*).—See *DIANTHUS.*

DEPTH TO PLANT BULBS.—See *BULB PLANTING.*

DERMASEA.—Now included in the genus *SAXIFRAGA.*

DESCHAMPSIA (Nat. Ord. Gramineæ).—This is a genus of weedy grasses of no garden value whatever, though sometimes recommended as being good wild garden plants. *D. caespitosa* is the well-known TUSSOCK GRASS, while *D. flexuosa* is popularly known as BENT GRASS. This last must not be confused with the weed described by that name in our article on *WEEDS,* which botanically is *Agrostis vulgaris,* as the two are not synonymous.

DESFONTAINEA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

DESIGN.—See *GARDEN DESIGN.*

DESMODIUM (TICK TREFOIL. Nat. Ord. Leguminosæ).—A good many species of this genus are stove evergreen shrubs, and are thus out of the scope of the present volume. The few that concern us are hardy herbaceous perennials succeeding in light, rich soil, to which some peat has been added, and in a sunny site. They may be propagated by division of the roots in the spring and planted in March. *D. canadense,* the TELEGRAPH PLANT, is one of the best species. It bears purple flowers in July, and averages 6 ft. in height. *D. paniculatum* and *D. rotundifolium* are two other good sorts. The first bears purple flowers and the second white. Both bloom in July, and average 2 ft. high.

DEWBERRY (*Rubus caesius*).—See *SHRUBS.*

DIAMOND BACK MOTH.—See *INSECT PESTS.*

DIANTHUS (PINK. Nat. Ord. Caryophyllaceæ).—The genus Dianthus is an extensive one, and comprises numerous species of high

garden value, while it has also given rise to a great number of varieties and hybrids, too numerous to detail in a work of this description. Of the species in cultivation by far the greater proportion are perennials, but a few annuals and biennials are of some value. Many of these have, however, been greatly overlooked by gardeners, mainly through the deservedly high place taken by the varieties of *Dianthus plumarius*, the GARDEN PINK; *D. Caryophyllus*, the CARNATION; *D. chinensis*, the popular annual or biennial INDIAN PINK; and *D. barbatus*, the SWEET WILLIAM, all of which are treated more fully elsewhere. Many of these species are of extreme beauty.

Culture.—The cultivation of the plants is generally easy, and most of them succeed if given the usual treatment of ordinary border or rock plants. Their general habit will, however, be a good guide to their requirements. Those with vigorous growth and large foliage are usually easy to grow in ordinary soil, if this is not too heavy, and are almost invariably lime-lovers. Those of close, tufted habit, such as *Dianthus alpinus* and *D. Freynii*, appear to prefer a compost of loam, leaf-soil, sand, and grit in about equal proportions, and are greatly benefited by being top-dressed in the spring and autumn, working some fine soil of the same nature in among the foliage with the fingers.

Propagation.—Practically all the Dianthuses may be propagated by means of seeds, but the hybrids and meritorious varieties are increased by division, cuttings, and, in some cases (*e.g.*, those with the same habit as the GARDEN PINKS), by pipings, or parts of the shoots pulled out at a joint and inserted in sandy soil under glass.

Seeds of the Dianthuses may be sown under glass in spring, either in shallow drills in a frame, or in pots, pans, or boxes, employing an open compost, such as that used for seeds of other hardy flowers. Some of the more robust species can even be sown in the open, preferably in sandy soil in shallow drills about 6 ins. apart, sowing the seeds very thinly about ¼ in. deep, and thinning out the seedlings to about 6 ins. apart.

The annuals, or more tender biennials, such as the INDIAN PINKS, *Dianthus chinensis*, can be sown thinly where they are to bloom, or earlier in pots or boxes under glass; the seedlings being duly pricked out, hardened off, and finally put in their outdoor quarters at the end of May. The hardier biennials, such as the SWEET WILLIAM (*Dianthus barbatus*), should be sown in shallow drills in the open or under glass in May, June, or July. Early sowing is best, and the work is frequently delayed far too long. The seedlings should be pricked off 6–10 ins. apart as soon as they can be handled. If bushy plants with several spikes are desired, the points of the seedlings may be pinched after they have been pricked out for about a month. They may be planted out finally where they are to bloom in autumn or spring. Specially good varieties may be propagated by striking side-shoots or by layering them, and this method must be adopted to perpetuate the old Double Dark Crimson Sweet William.

What to Grow.—Below we briefly describe the best sorts out of several hundreds which are now known:—

Dianthus alpinus.—The ALPINE PINK, with red or white flowers in May. Height, 4 ins.

D. arboreus.—The TREE PINK, with pink flowers in July. Height, 18 ins.

D. arenarius.—The SAND PINK, with pink flowers in July. Height, 6 ins.

D. Armeria.—The DEPTFORD or THRIFT PINK, with red flowers in August. Height, 12 ins.

D. arvernensis.—The AUVERGNE PINK, with rose flowers in May. Height, 6 ins.

D. atrorubens. — The CRIMSON PINK, with deep crimson flowers in July. Height, 18 ins.

D. barbatus.—The SWEET WILLIAM, with flowers in various colours from June onwards. Height, 6–12 ins. (See article on *SWEET WILLIAM.*)

D. caesius.—The CHEDDAR PINK, with rose-pink flowers in June. Height, 9 ins.

D. calalpinus.—Crimson flowers in June. Height, 4 ins.

D. callizonus.—The ZONED PINK, with crimson flowers in June. Height, 2 ins.

D. capitatus.—The CLUSTER PINK with crimson flowers in June. Height, 12 ins.

D. Carthusianorum.—Red flowers in July. Height, 18 ins.

D. Caryophyllus. — The CARNATION, with flowers in various colours from July onwards. Height, 18 ins. (See article on *CARNATIONS.*)

D. chinensis.—The INDIAN PINK, with flowers in various colours from July onwards. Height, 9 ins. (See article on *INDIAN PINKS AND JAPAN PINKS.*)

D. ciliatus.—The CILIATED PINK, with pink flowers in July. Height, 18 ins.

D. cinnabarinus. — Cinnabar-red flowers in July. Height, 12 ins.

D. cruentus. — The BLOOD-RED PINK, with red flowers in July. Height, 10 ins.

D. deltoides.—The MAIDEN PINK, with red or white flowers in June. Height, 6 ins.

D. dentosus.—The AMOOR PINK, with violet-lilac flowers in June. Height, 6 ins.

D. floribundus.—Rose-pink flowers in July. Height, 12 ins.

D. fragrans.—The FRAGRANT PINK, with white flowers in July. Height, 12 ins.

D. Freynii.—Pink flowers in June. Height, 2 ins.

D. furcatus.—The FORKED PINK, with red flowers in July. Height, 12 ins.

D. gallicus.—Purple flowers in August. Height, 9 ins.

D. giganteus.—The GIANT PINK, with purple-red flowers in August. Height, 36 ins.

D. glacialis.—The GLACIER PINK, with red flowers in July. Height, 3 ins.

D. gracilis.—Rose flowers in July. Height, 6 ins.

D. graniticus. — The GRANITE PINK, with red or white flowers in June. Height, 9 ins.

D. hirtus.—The HAIRY PINK, with red flowers in July. Height, 12 ins.

D. hybridus.—The MULE PINK, with flowers in various colours from June onwards. Height, 12 ins.

D. microlepis.—Red or white flowers in June. Height, 3 ins.

D. monspessulanus.—The MONTPELIER PINK, with red or white flowers in July. Height, 12 ins.

D. neglectus. — Rose - coloured flowers in June. Height, 3 ins.

D. nitidus.—The SHINING PINK, with pink flowers in July. Height, 6 ins.

D. noeanus.—White flowers in July. Height, 12 ins.

D. petraeus.—The ROCK PINK, with white flowers in July. Height, 6 ins.

D. pinifolius.—Pink flowers in June. Height, 2 ins.

D. plumarius.—The GARDEN PINK, with flowers in various colours in June. Height, 9 ins. (See article on *PINK.*)

D. pungens.—Pink flowers in July. Height, 12 ins.

D. rupicola.—Red flowers in June. Height, 12 ins.

D. squarrosus.—The SQUARROSE PINK, with white flowers in July. Height, 12 ins.

D. Sternbergii. — STERNBERG'S PINK, with pink flowers in June. Height, 15 ins.

D. suaveolens.—White flowers in July. Height, 12 ins.

D. superbus.—Rose flowers in July. Height, 12 ins.

D. sylvestris.—Rose flowers in July. Height, 12 ins.

D. tener.—Red flowers in July. Height, 6 ins.

D. zonatus.—White flowers, spotted red, in July. Height, 3 ins.

See also articles on *CARNATIONS, INDIAN PINKS AND JAPAN PINKS, PICOTEE, PINK,* and *SWEET WILLIAM.*—S. A.

NEW VARIETIES.

Dianthus Allwoodii. See article on *ALLWOODII.*

D. microlepis rumelicus.—This has rosy-pink flowers and short stiff sea-green leaves. It grows 1–2 ins. high, and is suitable for rock garden culture.

D. Miss Gladys Cranfield.—This bears bright pink-fringed single flowers, and is a very free bloomer. It is suitable for edgings to borders.

D. neglectus Aurora.—This bears rosy-carmine flowers, and dark green leaves. It is suitable for rock garden culture.

D. woodfordiensis.—This has rose flowers on which is a dark zone, and its leaves are dark green. It is suitable for rock garden culture.

W. J. C.

DIANTHUS LEAF SPOT.—See *DISEASES OF ROCK PLANTS.*

DIARY.—See *GARDEN DIARY.*

DIASCIA (Nat. Ord. Scrophulariaceæ).—One species of this genus, *D. Barberæ,* is a half-hardy annual which is well worth growing. It bears bright salmon-pink flowers from early August onwards, and averages 9–12 ins. high. It requires none but the usual culture of half-hardy annuals.

DIASTASE.—A ferment necessary for successful germination. See under FERMENTS in *GERMINATION OF SEEDS.*

DIBBERS: Their Use and Abuse. The dibber is a tool greatly used, but much abused by nine-tenths of the present-day gardeners. Its use lies in the fact that it can be used for the speedy planting of young seedlings of the cabbage tribe which have not got masses of fibrous roots. It can also be used for the speedy setting of cuttings of all kinds. For this purpose it should be very bluntly pointed—the usual dibber made of an old spade handle, and sharpened very much to a point, is not nearly so good.

The abuse of the dibber is in its use as a means of setting such seed tubers as artichokes or potatoes, for planting such crops as broccoli, cauliflowers, or indeed anything possessed of a good ball of roots. For this purpose it is worse than useless.

When such planting is done, a large cavity is left underneath the plants for the roots to form into. What happens is obvious. The roots are killed by the contact with sour air, and the plant dies speedily.

Such planting should be done with a trowel; it is more labour, but no modern gardener who means to be successful is going to shirk a bit of extra work. The modern man tells us he loves his plants. If this is true then it ought to be impossible for him to make them as unhappy as they can be by planting them carelessly with a dibber. Dibber-

planting is the lazy way, the crops are "stuck in anyhow," and it needs a man with a trowel to plant them properly as they should be.—E.

DIBBLES.—See *DIBBERS.*

DICENTRA (BLEEDING HEART, etc. Nat. Ord. Papaveraceæ).—An attractive genus which may be grown out of doors in the rock garden and in the herbaceous border, as well as indoors.

Outdoor Culture.—This is not a matter of great difficulty. The plants may be grown in any good soil, but a rather warm, sunny site, sheltered from cold winds, is desirable, as also is a little winter protection. Propagate by division in March or April, or by cuttings later, and plant any time from November up to the end of March, but in cold exposed districts spring planting is recommended.

What to Grow.—The following may be included, but for many additional species larger works must be consulted:—

Dicentra canadensis.—A white, May flowering sort, about 6 ins. in height.

D. chrysantha.—A desirable yellow sort, blooming in the autumn (September), and growing about 3 ft. in height.

D. eximia.—A pretty purple-crimson species, blooming in May and June, which grows about 1 ft. high.

D. spectabilis.—This is also known as *Dielytra spectabilis.* It bears purple-crimson or darkish-red flowers in July and August, and averages about 2 ft. in height.

D. thalictrifolia.—This, the hardiest of the newer Chinese Dicentras, is a graceful yellow species, blooming in June, and growing about 1 ft. in height.—E.

DICHELOSTEMMA.—Now included in the genus *BRODIAEA.*

DICTAMNUS.—See *FRAXINELLA.*

DICTYOGRAMME.—Now included in the genus GYMNOGRAMME, for which see *FERNS AND FERN GARDENING.*

DICTYOPTERIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

DIDYMOGLOSSUM.—Now included in the genus HYMENOPHYLLUM, for which see *FERNS AND FERN GARDENING.*

DIELYTRA.—Now included in the genus *DICENTRA.*

DIERAMA PULCHERRIMUM.—Better known as *Sparaxis pulcherrima.* See *SPARAXIS.*

DIERVILLA.—For the best species see *SHRUBS.*

DIETERIA.—Now included in the genus *ASTER.*

DIETES.—Now included in the genus *MORAEA.*

DIGGING.—See *SOIL CULTIVATION* and *WINTER GARDEN, THE.*

DIGITALIS (FOXGLOVE. Nat. Ord. Scrophulariaceæ).—This useful genus is mentioned in several articles. The best species for general purposes are given in our article on *FOXGLOVE*; those suitable alike for general and for water garden purposes, as well as for the wild garden, being briefly described in our article *WATER GARDEN: PLANTS FOR THE*, while the medicinal value of the plant and hints on its collection and culture in this connection will be found in our article on *MEDICINAL HERBS.*

DIGITARIA.—Now included in the genus *PANICUM.*

DIGRAPHIS.—Now included in the genus *PHALARIS.*

DILIVARIA.—Now included in the genus *ACANTHUS.*

DILL (*Peucedanum graveolens*).—See *MEDICINAL HERBS* and *PEUCEDANUM.*

DIMORPHOTHECA.—See *ANNUALS, HALF HARDY: LIST OF.*

DIODONTA.—Now included in the genus *COREOPSIS.*

DIOMEDES.—Now included in the genus *NARCISSUS.*

DIOSPYROS.—For the best species see *TREES.*

DIOTIS.—See *COTTON WEED.*

DIPLAZIUM.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

DIPLOSIS.—See PEAR MIDGE in *INSECT PESTS.*

DIPLOTAXIS (ROCKET. Nat. Ord. Cruciferæ). — This genus, on account of its English name, is sometimes confused with the better-known genus HESPERIS, as *H. matronalis* is also known as ROCKET. The present genus contains a number of hardy annual species of very little value for ordinary gardens, but interesting botanically as being one of the members of the large *Cruciferæ* order.

DIPSACUS (TEASEL. Nat. Ord. Dipsaceæ).—This is a genus of hardy biennial plants of very little garden value. The best garden sort is *D. pilosus,* the SHEPHERD'S ROD. *D. Fullonum,* the FULLER'S TEASEL, is useful industrially, while *D. sylvestris* is the well-known WILD TEASEL.

DIPTERIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

DISA.—See *ORCHIDS.*

DISBUDDING.

This is the removal of surplus buds, flowers, fruit, or shoots. It is not an operation the gardener can learn how to do from books. He must learn by practical experiment, or, better still, by being shown what to take or what to leave by some thoroughly experienced gardener.

DISBUDDING PEACHES. — See *PEACHES.*

DISEASES, NOTIFIABLE.—See *NOTIFIABLE DISEASES AND PESTS.*

DISEASES OF APPLES.—See *APPLE DISEASES.*

DISEASES OF DAFFODILS.— See ENEMIES AND DISEASES in *DAFFODILS.*

DISEASES OF FRUIT.—See *APPLE DISEASES; DISEASES OF PLANTS; ORCHARD: MAKING AND MANAGEMENT OF;* and *TOMATO DISEASES.*

DISEASES OF PLANTS.

The following notes contain descriptions of the various diseases which attack the gardener's plants. Remedies are given when known. Owing to the large amount of ground to cover, notes on individual maladies are necessarily brief. Where there are several important diseases which attack a certain plant, they are dealt with in a separate article after the article on the cultivation of that plant. For instance, the rose is attacked by Rose Canker, Rose Rust, Rose Mildew, and one or two other diseases. These will be found described with their cures in a separate article on *ROSE DISEASES.* The same applies to diseases of apples; we give them a separate article, *APPLE DISEASES.* Many apple diseases also attack pear trees, but the cures and remedies are the same for both.

It should not be forgotten that certain diseases are scheduled as notifiable under the Destructive Insects and Pests Acts of 1877 and 1907. Neglect to report them renders the gardener liable to a heavy fine. The most common of the notifiable diseases is Potato Wart Disease or Black Scab. The present writer hopes that before many years are past the authorities will realise the wisdom of scheduling Clubroot as a notifiable disease. The annual amount of damage this disease does must total many

millions of cabbages, at a cost of thousands of pounds. It is a plague, and will continue to be one until proper steps are taken to check it.

The best general method of keeping down diseases is thorough clean cultivation. We shall not enlarge on the meaning of this term here, but gardeners should take it in the broadest sense. Following these few remarks are notes on the chief diseases.[1]—EDITOR.

Anemone Rust (*Aecidum punctatum*). — A common disease in *Anemone coronaria*, and readily recognised by the large and very numerous cluster-cups on the leaves and stalks. The mycelium of the fungus is perennial in the rootstock and does not kill the host-plant. The alternate stage is the Plum Rust (*Puccinia pruni*), but in gardens the two fungi appear to occur independently.

REMEDIES. — Affected plants should be removed and destroyed.

Asparagus Rust (*Puccinia Asparagi*).—The cluster-cup stage of the fungus is rare, but the brown summer stage injures the stems that are left after the crop is cut, and by autumn they may be completely blackened. When the plants are severely attacked in this way the crowns are greatly weakened. The disease is not usually persistent, but sporadic.

REMEDIES.—To prevent a repetition of infection, spores must not be permitted to reach the ground. Diseased stems, therefore, must be cut out and burned before they die off. Very badly attacked plants are best entirely removed and destroyed.

[1] Mr A. D. Cotton, the writer of the notes on *DISEASES*, wishes to acknowledge his indebtedness to Mrs N. L. Alcock for her help in preparing this article.—EDITOR.

Azalea Leaf Blister (*Exobasidium rhododendri*).—This fungus causes the leaves of Indian Azaleas to become deformed and swollen, or forms roundish red and pinkish galls. The plants are disfigured, but the disease is seldom severe.

REMEDIES.—Affected leaves should be removed and burnt.

Bacterial Diseases.—Diseases of plants caused by bacteria are happily comparatively few, but several serious instances are known in Britain, such as Crown Gall, Blackleg of Potato, White Rot of Turnip and Swede, and Black Rot of the Cabbage Family. In addition, the tomato, iris, culinary pea, celery, and bulbs are sometimes attacked by bacteria. Bacteria are exceedingly minute organisms and devoid of mycelium. They multiply very rapidly and occur in enormous numbers, hence the amount of destruction they accomplish is considerable, and in the case of "soft-rot" this takes place with great rapidity. The general appearance produced by a bacterial disease is very similar to that due to fungi, and, except to the fully-trained eye, impossible to distinguish with certainty.

Bean Pod Canker (*Colletotrichum lindemuthianum*).—This appears on pods of French beans and scarlet runners as brown sunken patches, through which the disease may penetrate to the beans, infecting the seed for next season. The fungus usually first affects the young shoots, but is inconspicuous and hence is often overlooked.

REMEDIES.—It is most important only to use clean seed from unaffected crops. When the disease first shows itself, all affected portions should be cut off and burned to prevent it spreading.

Bean Rust (*Uromyces fabae*).—Bean Rust is exceedingly common on the broad bean and horse bean,

and is found also on wild vetches. The brown spore-pustules are only too familiar on the leaves and shoots, and the spores often occur in such immense profusion as to coat whole plants with a fine dust-like powder. The autumn or resting spores occur as black streaks on the stems.

REMEDIES.—The disease is not easy to control. (1) Burn and destroy all diseased material in autumn. (2) Select a new site the following year, as resting spores are sure to be present in the soil.

Beech Root Rot (*Armillaria mellea*).—This parasite, known also as HONEY FUNGUS, is very injurious to broad-leaved trees, especially to beech, and occasionally also to conifers. It is recognised by the honey-coloured toad-stools which arise from the root, and the strands of mycelium, at first white and later black, which run up the trunk within the bark.

REMEDIES.—Affected trees should be isolated by a trench 1 ft. deep, and diseased portions cut out. Dead trees should be cut down and removed.

Black Currant Rust (*Cronartium ribicola*).—The other stage of this rust occurs on Weymouth pines, which it attacks very seriously and eventually kills. The rust spreads easily to currants when grown in the vicinity, but only in a few seasons does it seriously injure them. It may be recognised by the yellow pustule on the back of the leaves.

REMEDIES.—Remove currants as far as possible from the neighbourhood of affected pines (which, if badly attacked, should be cut down), and spray with weak lime sulphur (1 part to 50 parts of water) if the disease threatens to be serious.

Black Rot of Cabbage and Cauliflower (*Pseudomonas campestris*).—The symptoms of this disease are the presence of black specks and streaks in the stems and leaves, coupled with the fading of the leaves. If attacked when young the plants often die. The disease is frequent in moist localities, and it attacks various cruciferous crops, especially those descended from rape.

REMEDIES.—Burn all diseased plants and stalks, and by means of a long rotation avoid using affected land.

Botrytis Cinerea.—This fungus is the exceedingly common grey mould found on all kinds of decaying vegetation when under damp conditions, both outdoors and under glass. Though usually a harmless saprophyte, it occasionally becomes parasitic, when it attacks living plants, especially bulbs, paeonies, geraniums, lettuces, and certain shrubs. The fungus forms a resting-stage, namely the small black bodies termed *sclerotia* found in the dead tissues of the attacked bulb or other plant. These perpetuate the fungus in the soil.

REMEDIES.—Strict cleanliness, the removal of all refuse and diseased parts, and the admission of plenty of light and air will greatly reduce attacks.

Canker Diseases. — Canker is a term employed by gardeners to express an open wound in the stem or flesh of a plant, and may be caused in a variety of ways. See under Canker of Apple, Bean-pod, Cucumber, Larch, Parsnip, Rose, and Tomato in this article, and in those on *APPLE DISEASES*, *ROSE DISEASES*, and *TOMATO DISEASES*.

Carnation Rust (*Uromyces caryophyllinus*).—This rust is apt to cause considerable damage, especially to plants under glass. The spore pustules (which are cinnamon-coloured) occur in pale areas on the leaves and are often found in clusters. Some varieties are apt to suffer badly.

REMEDIES.—(1) Remove affected

leaves. (2) Give plenty of ventilation. (3) If the rust is serious, spray with a weak fungicide to protect plants not attacked.

Celery Leaf Spot (*Septoria apii*). —This causes extensive damage, and should be dealt with directly it is discovered. Small discoloured patches appear on the leaf, which rapidly increase in size, and finally the whole leaf turns blackish and wilts. Minute black spots are found on the diseased leaves, and these contain the spores of the fungus.

REMEDIES.—Spray with Bordeaux or Burgundy Mixture two or three times in early summer as a preventive. In autumn, diseased foliage and stalks should be burned and not left to contaminate the soil. The fungus occurs on the seed, and thus the disease is perpetuated, hence it is important to use only seed from healthy plants.

Cherry Leaf-Scorch (*Gnomonia erythrostoma*).—Cherry trees attacked by leaf-scorch can be easily recognised in the winter and early spring by their dead leaves hanging persistently on the boughs. The fungus winters in the diseased leaves, ready to infect the young foliage and fruit in spring.

REMEDIES.—Pick off every diseased leaf in the winter, or spray thoroughly with Bordeaux Mixture first just before the flowers open, and again just after the petals fall.

Cherry Scab (*Fusicladium cerasi*). —This closely resembles the well-known scab on apples. Black or olive-green spots appear on the cherries, which, if attacked early, remain stunted and do not mature.

REMEDIES.—Spray with Bordeaux Mixture, or if scorching is feared spray with lime sulphur.

Chlorosis.—A physiological condition in plants indicating lack of chlorophyll is termed chlorosis. The leaves lose their normal colour and become pale or mottled with yellow. The exact causes are not fully understood, but it is known that lack of iron in the soil and occasionally excess of lime is liable to bring it about.

REMEDIES.—Dressing the soil with crushed sulphate of iron at the rate of ½ oz. per square yard, or watering pot plants with a weak solution of the same substance, often restores normal health.

Chrysanthemum Mildew (*Oidium Chrysanthemi*).—This is very widely distributed and common. It occurs outside, but usually causes most trouble after the plants have been brought indoors.

REMEDIES.—The mildew may be kept in check by supplying abundant air, by applications of finely precipitated sulphur or "flowers" of sulphur, or by the use of a sulphur vaporiser.

Chrysanthemum Rust (*Puccinia Chrysanthemi*).—This rust was probably introduced from Japan with chrysanthemum plants about 1895, and, for the first eight or ten years after its introduction, spread with great rapidity and caused much damage. Recently the fungus has been much less prevalent.

REMEDIES. — Select resistant varieties, and take care to avoid purchasing infected stock. Spray with dilute Bordeaux Mixture as soon as attacks are noticed, and remove very badly infected leaves.

Clubroot: FINGER-AND-TOE, or ANBURY (*Plasmodiophora Brassicæ*).—This is caused by a microscopic fungus which attacks the roots of Cruciferous plants, such as cabbage, cauliflower, turnip, radish, wallflowers, and stocks, also weeds, such as shepherd's purse and charlock. It produces irregular swellings and knotted distortions of varying size. Somewhat similar swellings are caused by the turnip gall-weevil, but

these can be distinguished from club-root by their rounded shape, and by the presence of a grub on cutting open. Affected plants become sickly and dwarfed. The fungus can remain alive in the soil for three years or more.

REMEDIES.—The only certain remedy is the application of lime in good quantity. Clubroot flourishes in a sour soil. Freshly-slaked and finely-divided lime should be applied and well dug in. Where the disease is bad, 1–2 lb. of lime per square yard, or 1½–4 tons per acre, is not too much. Chalk may be used if well crushed up, and should be given in double quantity. After five years lime should be applied again. Acid manures, such as superphosphate and sulphate of ammonia, should be avoided, and basic slag, nitrate of soda, or bone-meal employed. Care should be taken to avoid infecting clean land. All diseased roots should be burned, and clubbed seedlings should not be planted out. Cruciferous weeds of all kinds should be exterminated.

Cluster Cup Fungi.—These fungi are so named from the fact that the spores are borne in minute cups, which occur in definite colonies or clusters on the leaf or stem. They represent a stage in the life-history of the *RUST FUNGI* (see separate article), and typical examples are found in the Anemone and Viola Rusts. For fuller details see *RUST FUNGI*, and also under the respective hosts.

Conifer Root Rot (*Fomes annosus*).—A very destructive fungus disease of conifers, especially larches. It is recognised by the white mycelium between the bark and the wood, and by the small cushion-shaped fruiting bodies on the roots or around the base. The disease spreads through the soil.

REMEDIES.—Dead trees should be cut down and removed, especial care being taken to remove the roots. Affected trees should be isolated by a trench 1 ft. deep, and diseased portions cut away.

Coral Spot (*Nectria cinnabarina*).—A common saprophyte on deciduous trees and shrubs, but sometimes also parasitic. It attacks gooseberries, currants, and other woody plants, entering by a wound or dead twigs. The pink-coloured masses of spores on the wood are conspicuous and very distinctive.

REMEDY.—Cut back to sound wood, and burn all diseased branches.

Crown Gall (*Bacillus tumaefaciens*). This disease (which has been referred to the action of this bacillus in America) forms large woody lumps, varying in size from a walnut to a child's head, on the roots of the plants. It occurs specially in young fruit stock, apples and plums suffering frequently and occasionally being killed off. In most cases the trees continue to live for some years. In this country the disease has never been thoroughly investigated, nor does it appear to cause much damage.

REMEDIES.—Diseased roots should be cut off and burned, and badly affected plants grubbed up and destroyed. Care should be exercised in purchasing young stock to avoid affected trees.

Cucumber Leaf Blotch Diseases (*Cercospora melonis* and *Colletotrichum oligochaetum*).—These two fungi, which resemble one another in the effect they produce, are occasionally very destructive to cucumbers under glass. The spots are at first small, but soon increase in size. The second fungus mentioned sometimes attacks the shoots in addition to the leaves. The affected areas bear masses of spores which readily spread the disease.

REMEDIES.—Diseased portions should be cut out and burned, and

the atmosphere kept on the dry side. Spraying is not usually very successful, the only real preventive being in the selection of varieties immune to the disease.

Currant Leaf Spot (*Gloeosporium ribis*).—This produces blotches on the leaves, and studs them with small raised spots on the upper surface. The spots represent spore pustules. In severe cases the leaves fall prematurely and the tree is weakened. Gooseberries also are attacked by the same fungus.

REMEDIES.—Spraying with Bordeaux Mixture early in the season will prevent the disease obtaining a foothold.

Damping Off (*Pythium De Baryanum*).—A disease only too well known, and caused as a rule by the minute soil fungus *Pythium*. Affected plants fall over and die. The fungus forms resting spores, which persist in the soil, and under suitable conditions these germinate and attack young plants.

REMEDIES.—Sow thinly; avoid damp, shady, close conditions; and use open, porous soil. When the disease is troublesome and occurs repeatedly, use only sterilised soil for sowing (sterilised either by heating to 150° F., or by formalin). As soon as the disease shows, remove affected plants with the surrounding soil, and sprinkle the seed pan with "flowers" of sulphur.

Euonymus Mildew (*Oidium Euonymi-japonicae*).—The leaves of the Japanese Euonymus especially near the sea are often affected with this fungus, which forms a very conspicuous white mildew. The fungus hibernates on the affected leaves and in lateral buds.

REMEDIES.—In mild attacks dust repeatedly with "flowers" of sulphur; in bad attacks cut affected shoots hard back in spring before growth commences, so as to remove all resting mycelium. Thin out shoots if bushes are very thick.

Fairy Rings.—The name given to the dark green circles that are found on lawns and poor pastures. In this country *Marasmius oreades* is most usually the cause. The fungus, starting from a centre, grows outwards in a circular manner, and after rains in summer and autumn, develops fruiting bodies (toadstools) at the edge, thus making the ring more obvious. Inside the circle the soil is impoverished, but just at the ring the death of the fungus tissues increases the available plant food, and the grass grows stronger. The fungus itself is partly parasitic on the grass, and just outside the ring of darker green the grass is lighter and poorer. The ring grows outwards to the untouched grass year by year, and increases in size.

REMEDY.—Apply lime or basic slag at the rate of 4 oz. per sq. yard.

Fasciation.—The abnormal growth and fusion of parts in a shoot, forming a swollen, flattened structure, is termed "fasciation." It is a phenomenon common to all classes of plants. These extraordinary growths may occur in circumstances of extra rich soil, or extra moisture, and can sometimes be continued, if the same conditions are maintained, as for example the cockscomb-like inflorescence of celosia and the abnormal head of cultivated cauliflower. The fasciated appearance of witches' brooms on birches and fir trees is due in most cases to the stimulus of fungus or insect attacks.

Gooseberry Die Back (*Botrytis cinerea*). — The Dying-back of branches either large or small is a common occurrence in gooseberry. It is usually due to the fungus

Botrytis, but at other times no fungus is discernible, and the death is due to other causes. When attacked by Botrytis the grey spore-tufts of the fungus may usually be seen protruding through the bark.

REMEDY.—In either case the dead branches should be cut off, and if Botrytis is the cause, great care should be taken to cut back to sound wood and to burn the dead branches.

Gooseberry Mildew, American (*Sphaerotheca mors-uvæ*).—A serious disease of gooseberries which, when present in severe form, spoils the fruit, checks growth, and renders cultivation quite unprofitable. It may be recognised by the dense white mildew on the berries and young shoots, which soon turns to a thin fine felt, pale to dark brown in colour. The fine felt is the mycelium of the fungus in which the winter-spores are embedded.

TREATMENT. — Infected twigs should be cut out and burned in early autumn, before the spores fall from the felted mildew. In the spring (at the end of April), spray with lime sulphur, using the summer strength (1 part to 30 parts of water), and spray again after three weeks' interval. For the varieties *Lancashire Lad* and *Crown Bob*, double as much water is required.

Gooseberry Mildew, European (*Microsphaera grossulariae*).—Compared with the American mildew this disease is practically harmless. The fungus appears as a sparse white mildew on the leaves, especially when grown in the shade. In cases of severe attack it causes defoliation, which weakens the shoots and may bring about their death. Rusting spores are produced on the leaves in the autumn, which provide for fresh infection in the spring.

REMEDIES.—When an attack is feared, spray repeatedly with lime sulphur (1 part to 60 parts of water). Collect and burn fallen leaves in the autumn, and dig over soil under the bushes.

Grape Rot (*Gloeosporium ampelophagum*).—A fungus disease attacking the berries, leaves, and young shoots of the vine. On the berries the fungus causes characteristic circular spots with a well-defined border. On the young twigs it causes blackening and canker-like wounds.

REMEDIES.—Remove and burn all diseased parts. Dust the leaves and flowers with "flowers" of sulphur mixed with a small amount of powdered quicklime. Repeat, if necessary, every ten days.

Grapes, Shanking of.—A non-parasitic disease characterised by shrivelling of the stalk of the berries during the stoning period, which causes the latter to dry up and decay. The trouble usually indicates unhealthy root-action such as might be caused through the roots reaching an unsuitable soil, or through the border being too wet or excessively manured. Severe scalding or sudden defoliation may also bring about shanking. The remedy lies in rectifying the conditions noted above, and encouraging healthy root-action.

Gummosis or Gumming.—Stone-fruit trees of all kinds, if wounded in any way, will produce and exude abnormal amounts of gum. This exudation may be caused by mechanical injuries such as bruising, pruning wounds, frost, cracks, and insect or fungous injuries. Occasionally gum is formed in internal pockets in the tissue of the tree, or a kernel may fail to develop and be replaced by a gum deposit. The full explanation of gumming is little understood, and the whole

subject is in need of much further investigation.

Hollyhock Rust (*Puccinia Malvacearum*).—This Rust once made the cultivation of hollyhocks almost impossible, but though always more or less present, it is now much less virulent. The spore-clusters of the fungus occur as hard brown warts on the under side of the leaves and as elongated streaks on the stems.

REMEDIES.—Burn diseased leaves and stems in the autumn. Use clean seed, and sow and plant out in a new site. Choice varieties may be sprayed with a fungicide such as liver of sulphur, as a preventive, from spring onwards. Destroy affected malvaceous weeds.

Intumescences.—These are minute warts usually termed SAP WARTS by gardeners. They are not caused by fungus parasites, nor (unless insect galls be included) by insects, but by a disturbance in the transpiration of the plants. They are common on vines and pelargoniums in greenhouses, when the atmosphere is kept very moist and warm.

Larch Canker (*Dasyscypha calycina*).—A most destructive disease, which causes the branches to die off and which forms open cankerous wounds on the main stems and larger branches. Young trees are often killed.

REMEDIES.—The fungus enters the tree by means of small dead branches, and by injuries caused by wind, snow, or human agency. Dead branches and twigs should therefore be cut off, preferably in dry weather, and wounds pared over and tarred.

Mint Rust (*Puccinia Menthæ*).—This is very common in certain localities, especially the spring stage, which causes the stem to become swollen and deformed. The mycelium of the fungus is perennial in the rhizome, and consequently the disease reappears each season.

REMEDIES.—Affected shoots should be pulled up with as much of the rhizome as possible and burned. If this is done repeatedly, the disease may often be eradicated; if, however, it cannot be exterminated by this means, and is still troublesome, the whole bed should be dug up, and a new bed formed elsewhere from a fresh stock.

Mushroom Disease (*Hypomyces perniciosus*).—This attacks mushrooms growing in houses and occasionally destroys them wholesale. The mushroom does not develop normally, but forms a soft, shapeless mass, sometimes topped by a small, ill-formed cap. The parasite also attacks the spawn, causing the threads to become thick and fluffy.

REMEDIES.—The disease is difficult to deal with. It is infectious, and care must be taken to avoid carrying it to clean houses on manure or tools and boots. In bad cases all the manure should be cleared out, and a fresh start made by fumigating the house by burning sulphur.

Oak Mildew (*Oidium alphitoides*).—This conspicuous and well-known mildew only attacks oaks which have been cut back (*e.g.* hedges, coppiced oak) and seedlings. Large trees usually escape. The leaves are crippled and the shoots weakened. Winter spores are not known, but the fungus hibernates in the buds and hence reappears each season. No remedy is known.

Orchid Spot Disease.—The so-called Spot Disease of Orchids is familiar to all growers, though the cause has never been thoroughly explained. It is found chiefly on Cattleya, Dendrobium, Masdevallia, Odontoglossum, Phalaenopsis, and Vanda. The trouble commences as dark spots, often sunken, which increase in size and number. These

soon join up and form large, irregular blotches leading to the destruction of the whole leaf. No fungus can be found, the dark colour being largely due to accumulation of tannin. It is believed that Spot is in some cases caused by a chill through drops of water remaining on the leaf with a falling temperature, but in other cases this does not explain its origin, and the cause remains obscure. No satisfactory cure is known.

Parsnip Canker.—The decay on the shoulder of the parsnip root known as "Canker" or "Rust" is not due to a fungus parasite but to injuries of various kinds, such as growth-cracks, or to the work of slugs or carrot fly. These injuries do not heal, but permit the entrance of fungi, bacteria, and insects, which set up decay. Cracking, a frequent cause in bad cases, is liable to occur in all seasons and localities, but is worse when the late summer is wet and when much nitrogenous manure has been used.

REMEDIES.—(1) Dressing the land with lime previous to sowing, and applying salt at the rate of about 20 lb. per 5 rods, checks cracking. (2) Sow later, since parsnips sown in April or beginning of May, though not so large, crack less than those sown earlier. (3) Apply potash manures, which are useful for ensuring strong plants.

Pea Mildew (*Erysiphe polygoni*).—A very common disease of peas characterised by the presence of a copious white mildew on the haulm, and as a result a yellowing of the plants and early death. The damage is most severe in dry seasons and on light soils, and as a rule the mildew occurs more commonly on late peas. The winter fruits of the fungus are visible in late summer as black specks on the under side of the leaves.

REMEDIES.—Since drought undoubtedly favours the mildew, the best preventive is a good deep-rooting medium. Mulch, especially if the season is dry. In order to destroy resting spores, all diseased haulm should be collected and burned in the autumn.

Pea Streak (*Pseudomonas seminum*).—This expression denotes certain troubles which produce pale or dark streaks in the haulm of peas. In sweet peas the streak is usually pale, and since the cause is still obscure, no real remedy is known. In culinary peas the trouble is due to the bacterium *Pseudomonas seminum*. The discoloration is dark, and is seen in the stem, leaves, pods, and peas, in the tissues of all of which bacteria may be found. Affected plants die early and in any case produce practically no crop. Streak is mostly carried from season to season by means of affected seed, and occurs in many varieties of both dwarf and tall varieties of peas.

REMEDIES.—Great care should be exercised not to save seed from affected plants. These are therefore best pulled up as soon as noticed. All diseased haulm should be burned. The best seed should be purchased and sown preferably on a site where streak has not occurred. Good cultivation with a sufficiency of lime should be given.

Pear Leaf Cluster Cup (*Gymnosporangium clavariaeforme*).—The fungus genus *Gymnosporangium* requires two host-plants, living part of its annual cycle on rosaceous plants and a part on species of juniper. The large yellow cluster cups on the pear arise from spores produced by the juniper, and may be so abundant as to injure the tree. Gymnosporangium also occurs on hawthorn, medlar, and rowan. The remedy in each case is to remove the swollen diseased branches of the juniper.

Plum Rust (*Puccinia pruni*).—This leads sometimes to extensive defoliation of plum trees especially in Victorias. The under surface of the leaf is covered with brown powdery spots which in bad cases cause them to turn yellow.

REMEDIES.—The disease is seldom sufficient to require treatment, but spraying with dilute Bordeaux Mixture has been found useful.

Polyporus Diseases.—Various species of the fungus genus *Polyporus* attack trees and cause damage, especially in the case of old specimens. As these are often of value, care should be taken to prevent the entrance of such fungi by sawing off close to the trunk any branches which become broken off, and by tarring over all these and other wounds made on the trees. The mycelium of these fungi spreads widely on the trees, but if diseased branches are sawn off as soon as noticed the remainder of the tree may sometimes be saved.

Reversion in Black Currant.—This serious disease of black currants, also known as "Running off," is characterised by the production of sharp-pointed narrow leaves, "bunching" of the shoots, and "running off" of the fruit. The latter term indicating that, when the crops should be ripe, few or no berries are produced on the string. The precise cause or causes of Reversion are not known, but it is believed that in some cases it is induced by the repeated destruction of the terminal bud such as would follow attacks of currant mite (big bud). Although Reversion frequently follows and accompanies big bud, it is clear that the latter alone cannot always be responsible.

REMEDIES.—The only suggestions which can be made are to select varieties least subject to attacks, and never to propagate from affected bushes. Diseased bushes should be dug up and destroyed at once as they never recover.

Sclerotinia Diseases (*Sclerotinia sclerotiorum*).—In the fungus genus *Sclerotinia* is one species (*S. sclerotiorum*) which attacks a considerable variety of plants—viz. potato haulm, sunflowers, marrows, carrots in store, and other plants. Fortunately its occurrence is sporadic and local, but being a dangerous parasite, it occasions when present serious loss. Diseased patches are recognisable by the presence of copious white mycelium which is followed by the production of large, hard, white, and then black sclerotia, or resting bodies.

REMEDIES.—Drastic measures are necessary to prevent the disease spreading, and the sclerotia from reaching the soil. All diseased material should, as far as possible, be cut off or collected and burned. The application of lime to the soil is useless so far as destruction of these diseases is concerned, hence crops likely to be affected should not be grown on contaminated soil.

Silver Leaf (*Stereum purpureum*).—A disease affecting rosaceous trees and shrubs, especially apples and plums. Victoria and Czar plums suffer severely, and the former have been killed off in large numbers in parts of England. The disease is characterised by the silvery or leaden appearance of the foliage, a phase which is followed by the death of the affected branches. The fungus causing the disease enters through wounds, and attacks the inner tissues of the stem and branches; it is not visible externally until these are killed, when it appears as purple incrustations on the bark.

REMEDIES.—All dead trees or dead boughs should be removed and burned as soon as, or before, the fructification of the fungus

appears, so as to avoid further infection. In cutting back, sound wood should always be reached and the wounds made protected by tar.

Sooty Blotch (*Leptothyrium pomi*). —Sooty Blotch causes large blackish blotches on ripe and nearly ripe apples, as if marked with a dark mildew. The fungus is quite superficial, though it spoils the appearance of the fruit. The trouble is more prevalent in damp summers, and occasionally develops extensively in autumn. Affected apples may be cleansed by firmly rubbing with a damp cloth.

Sooty Moulds.—The fungi, *Capnodium, Fumago, Meliola,* and certain allied genera, all of which possess a black creeping mycelium, are sometimes classed together as "sooty moulds." These as a rule are only troublesome in gardens where aphis or scale insects are prevalent, as they thrive on "honey dew" and cover the leaves with a black mould where this substance is present. (See article on *Honey Dew.*)

Strawberry Leaf Spot (*Sphaerella fragariae*).—A very frequent complaint of strawberries which, however, only causes damage when the leaves are very seriously crippled. The spots are, as a rule, red or purplish with a grey centre, but they vary in appearance as other fungi besides Sphaerella cause similar spotting and are often present.

Remedies.—Dusting with black sulphur or "flowers" of sulphur checks the spread of the disease. In bad cases the tops may be mown in summer and the leaves raked off and burned.

Strawberry Mildew (*Sphaerotheca humuli*). — This fungus is very common on strawberries, sometimes only attacking the leaves, but at other times also the fruit, and especially in some varieties, causing much loss of crop or even total destruction. Both old and young fruit may be attacked. Affected leaves curl over and show their pink under-surface covered with mildew.

Remedies.—Dusting with black sulphur or "flowers" of sulphur early in the season, from mid-May, and repeating the operation at intervals of a fortnight if necessary, will often hold the mildew completely in check. For this purpose a "sulphurator" should be used, or a coarse canvas bag tied to the end of a stick from which the sulphur may easily be dusted.

Sycamore Leaf Blotch (*Rhytisma acerina*). — A very common and well-known fungus disease of the common Sycamore (*Acer Pseudoplatanus*), and other species of Acer. The fungus forms pitch black blotches on the foliage which disfigures the trees, and in bad cases causes premature leaf-fall, greatly weakening the wood. The disease commences in spring, arising from resting spores blown from the old diseased leaves of the previous season lying on the ground.

Remedy. — A determined effort to collect and burn diseased leaves in the autumn is the only known method of reducing the attack.

Vine Mildew or **Powdery Mildew** (of the Vine) (*Uncinula spiralis*).— A very common disease of both indoor and outdoor vines, but perhaps more destructive in the case of the former. The mildew, which is of the ordinary powdery type, covers the leaves with a thin white layer of mycelium and spores, which readily spread to the berries. No resting spores are formed in this country, but the mycelium hibernates in buds, and hence when once mildew has occurred, it is to be expected the following season, and from a few diseased shoots it easily spreads through a whole

house and to vines outside. There is no doubt that attacks of mildew are greatly facilitated by faulty culture, such as too close an atmosphere on the one hand, or faulty and draughty ventilation on the other, or indeed by dryness at the root, but even under the best management it may appear, and is not always easy to deal with.

REMEDIES. — Treatment should commence early. The old plan of placing sulphur on the pipes and heating them is good, as is also dusting with sulphur, but undoubtedly the best method of checking mildew is by the use of a sulphur vaporiser. Outdoors recourse must be had to spraying with Bordeaux Mixture.

Viola Rust (*Puccinia Violæ*).— This disease is very destructive to violas and violets. The fungus has three stages. The mycelium of the first or cluster cup stage is perennial, and grows up into the shoots each season, forming deformed swollen stems with small leaves. This stage occurs in spring and early summer, when the cluster cups are found on the under side of the leaves. The other stages follow in the summer and autumn, and are destructive to violets but not usually to violas.

REMEDIES. — (1) Good ventilation and plenty of space should be given, especially when grown in frames; and (2) as the fungus is perennial in the rootstock, cuttings should not be taken from infected plants, which should be destroyed.

Wallflower Mildew (*Peronospora parasitica*).—This fungus attacks beside wallflowers, such crops as cabbages, radish, turnips, as well as other cruciferous plants. In certain seasons whole beds of seedlings may be ruined.

REMEDIES. — (1) Remove and burn badly diseased plants. Those slightly affected should have diseased portions cut off. (2) Give ample room between the young plants, as in crowded beds the disease spreads rapidly. (3) After attack choose a new site, and do not plant wallflowers in the affected bed for at least two years.

White Rust of Crucifers (*Cystopus candidus*).—A very common fungus on wild cruciferous plants, especially shepherd's purse, and also occasionally found attacking cruciferous crops such as young cabbage, savoys, radish, and other garden plants. The fungus, which is not a true rust, but one of the Lower Fungi, produces large white blisters or swellings due to masses of spores which eventually burst through the epidermis as a white powder. Resting spores are formed in the diseased tissues. It is believed that the plants are only infected during the seedling stage, and that the fungus after infecting a plant grows along with it and forms the blisters some considerable time after.

REMEDIES.—The seed-bed should be made in a dry and open position, and all shepherd's purse and other cruciferous weeds kept down. Diseased plants in the seed-bed should be removed as soon as noted. In the case of old plants, little can be done beyond removing affected leaves as far as practicable. —A. D. C.

DISEASES OF ROCK PLANTS.

Few rock plants are subject to disease, and of those that die away, in many cases the cause is to be ascribed to excessive moisture about them in winter. (See ROCK PLANTS DISLIKING DAMP, in our article on *ROCK PLANTS FOR ALL PURPOSES*.) The following plants are occasionally attacked by the diseases named :—

DIANTHUS. LEAF SPOT.—Circular pale patches, with dark spots, on the leaves. Remove and burn infected leaves; avoid watering the foliage. Spray with any good fungicide.

GENTIAN. RUST.—Leaves turn yellow, and die. Spray, or take up and burn plant.

LITHOSPERMUM. MILDEW.—Spray with a reliable fungicide.

LYCHNIS. LEAF SPOT.—See *Dianthus* above.

PRIMULA VERA (and others). LEAF SPOT.—Large white spots with tawny margin. Spray with a reliable fungicide.

SAPONARIA. LEAF SPOT.—See *Dianthus* above.

SAXIFRAGA. RUST.—Treat as for *Gentian* above.

SEMPERVIVUM. HOUSELEEK RUST.—Infected leaves are longer, narrower, and paler than others. Destroy plants, as spray does not kill the disease.

THYME. DODDER.—Leaves lose colour, and have a parasitic growth on them. Destroy plants.

VERONICA. MILDEW.—This forms dense tufts on under-surface of leaves. Destroy plants, or spray.

A good and reliable spray is sulphide of potassium, a quarter of an ounce to a gallon of water.

W. J. C.

DOCKMACKIE (*Viburnum acerifolium*).—See *SHRUBS.*

DODDER.—See *CUSCUTA.*

DODECATHEON (AMERICAN COWSLIP.[1] Nat. Ord. Primulaceæ).—These are charming plants, with umbels of Cyclamen-like flowers. They thrive in a shady place in the rock garden, if deep, rich soil is provided, and are propagated by division of roots in the autumn. *Dodecatheon Meadia* seeds itself freely.

Rock Garden Species.—Only three species need be described here. For others which are little grown, larger works must be consulted.

Dodecatheon Jeffreyi.—Foliage in tufts. Flowers bright rose colour with yellow centre. Site, half-shade. Soil deep, rich. Flowering Period, May to July. Height, 1½ ft.

D. Lemoinei.—A hybrid between *D. Meadia* and *D. Jeffreyi* with flowers of various colours.

D. Meadia.—The easiest and best species. Flowers rosy-purple in large umbels. Site, shady. Soil, deep rich loam and peat. Flowering Period, May to June. Height, 1½ ft. The variety *album* has pure white flowers.—W. I.

DOG MANURE.

This is of little value for the garden, though not actually injurious as some gardeners imagine. It is rich in phosphates, and is best mixed with horse or farmyard manure and dug in in the usual way in the winter, but unless a pack of hounds are kept, or the garden is attached to a dogs' home, it is not

[1] Or SHOOTING STARS of some authorities.—EDITOR.

usually available in sufficiently large quantities to be troubled with.—E.

DOG-ROSE (*Rosa canina*).—See *ROSE SPECIES.*

DOG VIOLET (*Viola canina*).—See *VIOLA SPECIES.*

DOG'S MERCURY.—See *MERCURIALIS.*

DOG'S-TAIL GRASS.—See *CYNOSURUS.*

DOG'S-TOOTH GRASS (*Agropyron caninum*).—See *AGROPYRON.*

DOG'S TOOTH VIOLETS (*Erythronium.* Nat. Ord. Liliaceæ).—Dog's Tooth Violets, or, as they are sometimes called, ADDER'S TONGUES, are a pretty, unpretending race of bulbous plants, many of which come from North America. As a rule the foliage is mottled, and the petals tend to reflex. They like partial shade, hence they may be grown in thin woodlands and in north borders. They do not do well in pots.

Culture.—They like a damp, well-drained soil, and a partially-shaded position. The bulbs must not be kept out of the ground any longer than is necessary, as they resent being moved, nor must the best results be expected at their first time of flowering. It follows that they should be left alone as long as they flower well. An annual top-dressing of a mixture of light decayed manure and peat benefits them. They are increased by offsets and by seed, which last should be thinly sown in pans in a cold frame in August, and the seedlings grown on for two years before being planted out in the open; or if room can be found, in loose soil in a cold frame where they may remain until they bloom, when the best can be marked before they are put in their permanent places.

Species and Varieties.—Some of the best are described below:—

Erythronium americanum (YELLOW ADDER'S TONGUE).—This, a shy bloomer, bears bright yellow flowers in May, on plants 6–8 ins. high.

E. Dens-canis.—This is the COMMON DOG'S TOOTH VIOLET. There are numerous colour variations, some of which are named, *e.g. Frans Hals* (rosy-purple); *La Caudeur* (white); and *Matador* (rose, with especially beautiful foliage). The type has dull rosy flowers. All bloom in late April or May, and grow 6–8 ins. high. They will grow quite well in sunny positions if the soil is fairly moist.

E. grandiflorum.—This, and its sub-varieties *giganteum* and *revolutum* (Syns. *E. giganteum* and *E. revolutum*) are important flowers. The type bears yellow, and the forms bear yellow, rose-pink, and white flowers from April onwards, and grow 12 ins. high. Many named sorts of the latter are available, such as *Pink Beauty* and *Watsoni.*

E. Hartwegi.—This has pale yellow flowers in April, and grows about 6 ins. high. It stands heat better than most varieties.

E. Hendersoni.—This bears pale rose-purple flowers in May, and grows 8 ins. high.

E. nuttallianum.—This bears golden-yellow flowers in late April and May, and grows 6–10 ins. high.

E. revolutum.—This nursery sort is the sub-variety *revolutum* of *E. grandiflorum,* which see.

The nomenclature of Dog's Tooth Violets is very uncertain, so buyers should be careful when placing their orders.—J. J. & E.

DOGBERRY (*Cornus sanguinea*).—See *SHRUBS.*

DOGWOOD.—A name applied to the genus CORNUS, which see in *SHRUBS.*

DOLOMITE.—See *MAGNESIA AND MAGNESIUM COMPOUNDS.* See also under LIMESTONE in *ROCKWORK.*

DONAX.—Now included in the genus *ARUNDO.*

DONDIA.—See *HACQUETIA.*

DOODIA.—For the best species and varieties see *FERNS AND FERN GARDENING.*

DORONICUM (LEOPARD'S BANE. Nat. Ord. Compositæ).—This is a highly desirable plant for the herbaceous, shrubbery, or perennial border, as well as for the wild garden. It succeeds everywhere, alike in the smokiest cities and the sunniest villages. It will do in sun or light shade, and is probably one of the earliest truly herbaceous perennials to bloom. Certainly its flowers are hard to beat for cutting in the early spring. One thing is much against it, however, and that is its property of producing severe rashes or violent eczema on those who have sensitive skins. The present writer can handle it with impunity, but in any case it must be regarded as a doubtful plant more or less poisonous, and must be used with care. Children at all events should be forbidden to touch it, and the dead flowering stems should be promptly burnt.

Culture.—This is not a matter of any great difficulty. Planting may be done any time from late October to the end of March, though early planting is essential if early flowers are desired. The plant may easily be raised from seeds sown in the usual manner described in our article on *PERENNIALS: GENERAL CULTURE OF*; in addition to which the plants may be freely propagated from root cuttings or young basal growths from the crowns in late June and July. The usual method of increase is, however, division of the rootstocks, which can be carried out in the early winter or in February. Any ordinary soil is suitable. Cut down immediately after flowering, and apply a mulch of short manure and plenty of liquid manure if a second crop of flowers is desired. Lift at least once in three years, rejecting the worn out central portion of the clumps, and replanting the stronger outer sections.

What to Grow.—There are not many sorts to choose from. We recommend the following:—

Doronicum austriacum.—This golden-yellow sort, flowering in April and May, and again in the autumn, is hardly distinguishable from *Senecio Doronicum*, popularly known as LEOPARD'S BANE. Height, about 3 ft.

D. caucasicum.—This dwarfer sort is not so good as some. It bears yellow bloom in April, and grows about 1½ ft. in height.

D. Harpur Crewe.—Probably the most popular of all Doronicums. This is a dazzling yellow sort, flowering freely from March to June, and again in the autumn. Its height is about 3 ft. It is a variety of the following:—

D. plantagineum excelsum.—This too is a popular sort, and flowers with remarkable freedom. The large daisy-like blooms are yellow, and are produced freely through March, April, and May, with a few in the autumn. The height of this sort ranges from 2½ ft. to 4 ft.—E.

DORSET HEATH (*Erica ciliaris*).—See *HEATHS.*

DORYOPTERIS.—See *Pteris palmata* in *FERNS AND FERN GARDENING.*

DORYPHORA.—See COLORADO BEETLE in *INSECT PESTS.*

DOT PLANTS.—See list of CENTRE OR DOT PLANTS in *CARPET BEDDING.*

DOUBLE CROPPING.—See *ROTATION OF CROPS AND DOUBLE CROPPING.*

DOUBLE-FLOWERED HEATHER (*Calluna vulgaris flore pleno*).—See *HEATHS*.

DOUBLE-FLOWERING GORSE (*Ulex europaeus flore pleno*).—See *SHRUBS*.

DOUBLE HYACINTHS.—See *HYACINTH*.

DOUBLE PYRETHRUMS.—See *PYRETHRUM*.

DOUBLE or SHOW DAHLIAS.—See DAHLIA SECTIONS AND VARIETIES in *DAHLIA : CULTURE OF*.

DOUBLE SNEEZEWORT.—See *ACHILLEA*.

DOUBLE YELLOW ROCKET.—See *WINTER CRESS*.

DOUGLAS FIR (*Pseudotsuga Douglasii*). See *TREES*.

DOUGLASIA (Nat. Ord. Primulaceæ).—A beautiful Androsace-like plant, forming dark green, mat-like tufts. It thrives in moist, peaty soil, and is propagated by division in autumn or spring. It may also be grown from seeds sown in gentle heat in March.

Rock Garden Species.—Only two are usually grown. These are briefly described below :—

Douglasia laevigata. — A small, tufted plant. Flowers pink. Site, half-shade. Soil sandy peat. Flowering Period, May to June. Height, 3 ins.

D. vitaliana.—Easy to grow, making large tufts or mats. Flowers yellow. Site, half-shade. Soil gritty peat and loam. Flowering Period, May to June. Height, 3 ins.

W. I.

DOVER GRASS (*Festuca elatior*).—See *FESTUCA*.

DRABA (WHITLOW GRASS. Nat. Ord. Cruciferæ).—This is a genus of interesting and pretty rock plants easy to grow in gritty soil. They are best propagated by means of seeds sown in March. We recommend the following as being the best species :—

Draba Aizoon.—This bears dwarf tufts of sharp leaves. Flowers yellow. Site sunny ledge. Soil gritty loam. Flowering Period, March to April. Height, 3 ins.

D. bruniaefolia.—This forms large mats of evergreen leafage. Flowers yellow. Site sunny. Soil gritty. Flowering Period, May to June. Height, 3 ins.

D. dedeana.—This is a useful tufted species. Flowers white. Site sunny. Soil gritty. Flowering Period, May to June. Height, 2 ins.

D. imbricata.—This is another pretty tufted species. Flowers yellow, on wiry stems. Site sunny. Soil gritty. Flowering Period, May to June. Height, 3 ins.

D. pyrenaica (Syn. *Petrocallis pyrenaica*).—This forms a small tuft. Flowers rose-lilac. Site sunny. Soil gritty. Flowering Period, May to June. Height, 2 ins.

W. I.

DRACOCEPHALUM.—See *DRAGON'S HEAD*.

DRACOPSIS.—Now included in the genus *RUDBECKIA*.

DRAGON'S HEAD (*Dracocephalum*. Nat. Ord. Labiatæ).—This is the popular name of a genus of hardy annual, hardy perennial, and half-hardy evergreen plants. The first and last are of comparatively little importance, so need not concern us here. The hardy perennial sorts, of which a fair number have been described, are useful in the perennial or marginal shrubbery border, also in the rock garden and the richer portions of the wild garden. Ordinary good garden soil suits them admirably, and propagation by seed or division at the usual times is not difficult. Planting may be successfully undertaken from November to March. We recommend the following :—

Dracocephalum austriacum. — A useful blue midsummer flowering sort, about 12 ins. high.

D. grandiflorum.—This is the most

difficult to cultivate. It is a blue sort, flowering in July. Height, 12 ins.

D. nutans.—Similar to *D. grandiflorum.*

D. parviflorum.—A dwarf blue July flowering sort, suitable for the rock garden, growing only 6 ins. high.

D. Ruyschiana.—A blue sort flowering in July, and growing 1½ ft. high.—E.

DRAINAGE FOR ORCHARDS.—See *ORCHARD: MAKING AND MANAGEMENT OF.*

DRAINING.

Vegetation of any kind cannot be satisfactory if the land is wet and waterlogged. Not even grass will flourish, except the coarse and useless type. Rushes will soon predominate in low-lying pastures, and moss in higher altitudes will quickly smother the finer grasses in the fields, garden, or on lawns. Plants, trees, fruits, vegetables, and flowers must have water sufficient for their needs, but an excess of it about their roots causes stagnation. Under these adverse conditions plant-life quickly loses chlorophyll or green colouring matter, and ceases to make satisfactory progress until the evil is corrected. The obvious remedy, then, is drainage in some form.

Certain soils—those full of stones as in many of the southern counties—do not require artificial drainage, because the stones are a natural means of filtration for the surface soil. Where, however, the subsoil some 18 ins. below the surface is a hard, pan-like substance (a near approach to clay but not actually so), artificial drains are of little avail. The writer knows instances where kitchen gardens, when made, were most carefully drained in the proper manner, yet at the end of twenty years not one drop of water had passed through any of them.

In such soil as this, trenching to the depth of 2 ft. or more answers the same purpose as draining, and indeed is the only means of obtaining successful crops. What is needed is the breaking up of that hard, pan-like subsoil to admit of a steady percolation of surplus water from heavy rains. If once done thoroughly, no further trouble will be experienced.

Loams overlaying clay with no useful stones as a natural surface filter, need draining either by a thorough system of pipes or open surface channels, which in some cases answer a useful purpose to get rid of water from heavy rains quickly, before it has time to percolate through the surface loam to the subsoil of clay. Thus, when preparing a plot for a large or small kitchen and fruit garden, the constitution of the soil will decide whether it is essential to success that it should be drained.

The natural lie of the soil will determine which way to lay the pipes. Ordinary land drain pipes usually 1 ft. long in various sizes are the best to use, since water percolates through the joints, which last are not, of course, fitted together too tightly. The main drain pipes should be 3 ins. in diameter, that of the supply pipes being 2 ins. The ordinary sewage or socket pipes should not be used except in the case of a main drain carrying away a constant flow of water through which the roots of trees might push their way and thus choke up the drain. In that case the joints should be closely made with cement to prevent the ingress of roots.

Laying of Drains.—Having determined the natural outlet for the water, the main drains should be marked out at about 30 yds. or 50 yds. apart. The side or supply pipes need to be about 15 yds. apart, and should be arranged in diagonal lines on either side, con-

necting each set with the main drains. If possible the latter should have a fall of at least 1 in. in 20 ft., or better still would be a slope of 1 ft. per 100 ft., if this can be managed, with the side drain sloping similarly. All should be truly laid with the aid of the square-edge and spirit-level.

Before filling in the drains it is well to see all are correctly laid; if there are irregular portions in the base of the drain, such may be a permanent cause of trouble, as we need hardlysay water will not flow uphill by natural laws. All drains should be covered with brushwood, hedge trimmings, or other similar filtering materials, which maintain porosity so much better than closely fitting clay soil over the joints.

Draining Garden Paths.— Where a kitchen or flower garden is on the level, or nearly so, some provision should be made for getting rid quickly of surplus water.

The most simple method is to lay one 2–3 inch drain down the centre of each path, connecting each of these with short drains from catch-pits on each side of the path. These pits should be built with dry bricks; they should not be less than 9 ins. in diameter and 1 ft. deep. These sizes answer for 4-foot paths. For wider paths or for a greater quantity of water, the catch-pits should be built accordingly.

The outlet pipes should be immediately under the grating at the top of the pit, thus allowing for a greater bulk of silt in each pit. If the garden is square or rectangular, the pipes in each path will run to a main drain at the bottom, meeting them at right angles.

In the case of abruptly sloping ground, in spite of drains and well-made catch-pits, heavy rains often create a rush of water more than the drains can take. All too often the result is that gravel is washed to the lowest point of the path, choking the catch-pits in its rush, impelled by the force of the water.

The remedy for this is not to lay drains in such paths at all, but to substitute side-channels in the path on the margin. These are formed with a 2-inch layer of concrete, and are faced with gravel of the same colour as the path. The channels should be in width of a size consistent with width of the path. For a 4-foot path the channels should be 6 ins., and for a carriage drive 12½ ft. wide, 1 ft. should be left on each side. At varying distances catch-pits should be built in the channels or just off them in the margin, connecting these with drains to convey the water to a place of safety, such as a pond or tank built in a convenient site for the use of cattle, perhaps, or for the garden during a drought.—E. M.

DRY WEATHER PLANTING.—See *BEDDING OUT.*

DRYAS (MOUNTAIN AVENS. Nat. Ord. Rosaceæ).—This genus of evergreen trailing plants, with

shrubby stems and small oak-like leaves, thrives on half-shady ledges in the rock garden. It may be propagated by division of the roots in the spring, by cuttings out of doors in July, and also by seeds in heat in March. The two best species are :—

Dryas Drummondii (Syn. *D. chamaedryfolia*).—A trailing sort with nodding golden-yellow flowers. Site half-shade. Soil gritty loam. Flowering Period, June to July. Height, 4 ins.

D. octopetala.—A free-growing trailer with pure white flowers. Site half-shade. Soil gritty loam. Flowering Period, June to July. Height, 3 ins. Its variety *lanata* has attractive woolly leaves.—W. I.

DRYING OF FRUITS AND VEGETABLES.—A word may here be said as to the drying of one's own fruit, etc., at home, simply using the sun or oven. The former is a splendid dryer, but, unfortunately, in the greater part of this country there are seldom many successive days of hot sunshine, and artificial heat has to be resorted to. Now where an ordinary kitchen range is heated by coal, there is always a certain amount of heat which need not be allowed to waste, as it will help nicely with the drying of one's produce.

The first thing necessary is to provide some trays for drying, and these can easily be made at home by tacking together four strips of wood about 3 ins. deep, and stretching coarse muslin or canvas over the frame when finished, tacking this down. The produce about to be dried is spread on the tray, one layer deep, prior to exposing it to the heat. It is impossible to state any definite length of time required for drying special fruits, etc., as so much depends upon the sun or oven heat and for how long it is continuous. Care and patience are both required when one is conducting drying operations, and it should always be remembered that the produce is to be *dried* and *not cooked*, therefore the heat must only be gradual and never too intense, as if once the fruit becomes hardened, it will never be properly dried. The temperature should be between 160° F. and 200° F., and it is a good plan always to leave the oven door open while produce is inside, in order to avoid any danger of overheating, and also to allow the moisture to escape outwards.

When the produce is thoroughly dried, the best method of storage is to keep it in bottles or tins away from the air ; but frequent examination is advisable, and if there are any signs of damp, spread the contents again on the tray, placing it in the oven for an hour or so.

The following dry very successfully :—

Apple rings, apricots, currants, grapes (for raisins), pears (halved), and plums.

Beans and shredded carrots, peas, etc., for soups, also onions, will dry equally successfully.—E. C.

DRYING OF VEGETABLES.—See *DRYING OF FRUITS AND VEGETABLES.*

DRYING-OFF BULBS.—See *BULBS : CLEANING AND STORING.*

DRYING POULTRY DUNG.—See *POULTRY MANURE.*

DRYNARIA.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

DUCK FOOT.—See *PODOPHYLLUM.*

DUCK MANURE.—See *POULTRY MANURE.*

DUCK NUT.—An old variety of WALNUT. See WALNUT in *NUT CULTURE.*

DUCKWEED (*Lemna.* Nat. Ord. Lemnaceæ).—Various kinds of Duckweed often prove troublesome in stagnant ponds, pools, or lakes in the water garden, but do not as a rule grow in running water. One remedy therefore is almost obvious: avoid having stagnant water in the garden. Duckweed can generally be destroyed by rendering the water slightly acid, and a small quantity of sulphuric acid is the material usually employed. This, however, cannot be considered a safe remedy where other choice water plants are being grown, as it may have a very detrimental effect on them.

EASTERN PLANE (*Platanus orientalis*).—See *TREES.*

EASTERN SPRUCE (*Picea orientalis*). See *TREES.*

ECCREMOCARPUS.—For the best species see *CLIMBING AND TRAILING PLANTS.*

ECHEVERIA.—Now included in the genus *COTYLEDON.*

ECHINACEA (Nat. Ord. Compositæ).—This is a genus of hardy herbaceous perennials of very easy culture. It will succeed in ordinary light rich loam in most districts, and is not hard to propagate by summer-sown seeds or root division in March, at which latter period it may be successfully planted. It is a favourite plant with many exhibitors of hardy flowers.

Echinacea purpurea is the best species. This bears red or reddish-purple flowers in August and September, on plants 3–4½ ft. in height.

ECHINOCACTUS.—A genus of cactaceous plants. See *CACTI.*

ECHINOCEREUS.—A genus of cactaceous plants. See *CACTI.*

ECHINOCHLOA.—Now included in the genus *PANICUM.*

ECHINOPS (Nat. Ord. Compositæ). This genus, known by some people as the GLOBE THISTLE, includes some useful hardy perennials which are very good bee plants. It may be used in the perennial border, shrub border, or even in the wild garden.

Culture.—This is simple and easy. The plant succeeds in any good garden soil in a hot sunny site, and is easy to increase by seeds sown in the usual way described in our general article on *PERENNIALS.* It may also be increased by root division in the autumn or spring, and may be planted any time from November to the first week in April.

What to Grow.—A few good sorts are named below :—

Echinops bannaticus.—By some authorities this is described as a biennial, but it will live for three years or more. It is a blue-flowered sort, in which there is some purple or violet, and blooms in July and August, averaging about a yard in height. There is a desirable white variety of this, named *albus.*

E. dahusecus.—A blue August blooming sort, averaging 3 ft. in height.

E. exaltatus.—A tall white July blooming sort, attaining 2 yds. in height.

E. graecus.—A blue sort, flowering at the same time as *E. exaltatus,* but only about 2 ft. high.

E. humilis.—A desirable dwarf blue June flowering sort, averaging 1½ ft. in height.

E. Ritro.—Undoubtedly the best sort of all. There are several varieties all blue, which bloom from June to August, and which vary in height from 2 ft. to over a yard.

E. sphaerocephalus.—A useful, light blue sort, blooming from July onwards. Its height varies from 2 ft. to 4 ft. There is a useful white variety named *albidus.*

E. tauricus.—A blue sort, flowering during August, about 1½ yds. high.

ECHINOPSIS.—A genus of cactaceous plants. See *CACTI.*

ECHTHRONEMA.—Now included in the genus *SISYRINCHIUM.*

ECOLOGY.—See *BOTANY FOR GARDENERS.*

EDELWEISS.—See *LEONTOPODIUM.*

EDGING.—See *GARDEN EDGINGS.*

EDGING BOX (*Buxus sempervirens suffruticosa*).—See *SHRUBS*.

EDGING : HALF-HARDY PLANTS FOR.—See *EDGING PLANTS : HALF-HARDY*.

EDGING : HARDY PLANTS FOR. Many fine groups of Hardy Plants are available for use as Edging Plants, and the garden-maker has a wide and varied choice when selecting.

Edgings may briefly be defined as "formal" and "informal." In the first, the plants should be as neat in growth and as uniform in blossom and colourings as possible. "Informal" plantings give the planter more scope in the choice of subjects, and are greatly preferable.

Leaving out the usual edging subjects, such as *Buxus sempervirens, Lavandula Spica,* shrubby Veronicas, etc. (which are really shrubs pure and simple, and therefore cannot be regarded by the simple definition of Hardy Plants), a wide choice is open to us. Some of these are mentioned below :—

Anemones such as A. blanda, Hepatica, sylvestris, etc., are charming.

Arabises such as A. alpina, alpina variegata, albida, and albida flore pleno are widely used. The albida section are very aggressive, and need constant replanting.

Armerias, or Sea Pinks, are very pleasing, especially the dwarf brightly coloured varieties.

Astilbes of the newer and more charming species and varieties are splendid for fringing informal pathways in moist places.

Aubrietias are excellent. Neat, dwarf, floriferous, and very showy in colour. Varieties like Dr Mules, Lady Marjorie, Lavender, and Triumph are very desirable, planted separately, though seedlings of a first-class strain are glorious when grown intermixed as informal edgings on the raised sides of pathways.

Campanulas are of first-rate importance. All the carpatica group are heartily recommended. C. pulla and varieties of the pumila and pusilla groups make very pleasing effects, and many of the hybrids, such as Profusion, Stansfieldi, and others, are exceedingly good.

Cerastiums, owing to their aggressive root action, cannot be recommended, unless utilised for poor, dry soils.

Corydalis—especially such forms as C. chielanthifolia and C. nobilis—make pleasing edgings.

Dianthuses are extremely serviceable. Species such as D. caesius, deltoides, etc., are charming, and the newest hybrids, which include gracilis and Rosalind, are exceptionally good.

Ericas, though hard-wooded, shrubby plants, make splendid edgings, especially E. carnea, carnea alba, and mediterranea hybrida.

Erigerons can be utilised in a large measure, especially the continuous flowering E. mucronatus.

Gentians, though so well adapted for rock garden plantings, can be used if necessary. Notable forms such as G. acaulis, acaulis alba, asclepiadea, septemfida, and verna are suitable.

Geraniums of the best hardy sorts are permissible.

Geums such as G. Heldreichii, maximum, and montanum can be utilised.

Gypsophilas, especially G. repens monstrosa and Sundermanni, are also very pleasing.

Heleniums, including H. grandiflorum and pumilum, make good edgings.

Helianthemums, or Sun Roses, can be safely relied on, especially the neater double-flowered varieties.

Heucheras one can plant freely. They are ideal, especially Beacon, Rosamunde, Scarlet Spray, St Osyth, and similar free-flowering varieties.

Hypericums, with their sheets of golden blossoms, are glorious.

Iberis is invaluable for making snowy drifts of blossom. I. correaefolia, garrexiana, sempervirens, superba, and other effective forms are ideal.

Kniphofias of the types of K. Goldelse and Torchlight are excellent.

Lithospermums, particularly L. Heavenly Blue and L. prostratum, are worthy of note.

Mimulus furnishes a wealth of varied colourings for the purpose.

Nepeta Mussini is good, especially where there is plenty of space. It can be associated with Lavender.

Phloxes of the setacea and subulata groups furnish many neat, attractive dwarf plants. P. atropurpurea, Brightness, G. F. Wilson, lilacina, Nelsoni, and others may be looked upon as especially choice subjects. The low-growing herbaceous Phloxes such as P. carolina, divaricata, divaricata alba, and Laphami are of much value and surpassing beauty.

Pinks (see also DIANTHUS) make good edging subjects, especially for formal work. Varieties such as Her Majesty, Mrs Sinkins, Progress, and Snowdrift are very desirable.

Plumbago Larpentae makes a good blue-flowered subject, very hardy and attractive *en masse*.

Polemoniums such as P. Richardsonii can be used.

Polygalas are useful for small edgings.

Primulas are capable of great effects. P. Beesiana, pulverulenta, sikkimensis, and others are grand for moist situations. The Alpine types are excellent in drier positions. P. Auricula, golden-yellow, and P. Auricula Revolution, brilliant red, are wonderfully fine.

SAXIFRAGES furnish a host of worthy subjects, ranging from the large-leaved S. Megasea to the very dwarf species such as S. apiculata, Boydii, Pseudo-sancta, Salomoni, sancta, etc.

Mossy Saxifrages are favoured for cool pathways, and of these we can heartily recommend S. Arkwrightii, Beacon, ceratophylla, Fire King, hypnoides, Red Admiral, rheimagnifica, and Wallacei as being typically useful plants.

Silver Saxifrages are best represented by such forms as S. cochlearis, Cotyledon, lantoscana superba, lingulata superba, macnabiana, etc.

Saxifraga umbrosa is widely used; it is neat, but rather short-lived in blossom. Nearly all the dwarfer species in the article on *SAXIFRAGA* can be used.

Sedums—though not equal to the Saxifrages in value—can be freely used, especially such species as S. glaucum, obtusatum, rupestre, sexangulare, spathulifolium, and spurium rubrum.

Silenes can be used, selecting the best species.

Spiraeas (like Astilbes) furnish a considerable variety of good material for bold work.

Tiarella cordifolia is good, contributing pleasing effects in drifts, with its abundant foamy blossoms.

Verbena chamaedryoides should be chosen for its brilliant scarlet colouring. Nothing exceeds it in effect, and a five years' test in an East Coast garden has proved its value and hardiness.

Veronicas of the dwarfer types offer some useful plants. V. incana, rupestris, and verbenacea, as well as the taller subsessilis, are good types, while the tiny shrubby gems such as V. Catarractae, white, and Heavenly Blue are very fine.

Vincas should only be used in cases of necessity, but are useful in shade and in poor soils.

Violas are first rate. Especially would we draw attention to V. gracilis, violet blue, and the many fine varieties and hybrids of recent origin. These are the most glorious of all edgings plants, and are hardier and more floriferous than the much esteemed florists' Violas (see the special article on *Viola*). All varieties are worthy of consideration for edgings.

Zauschneria californica should not be omitted. It is another grand scarlet-flowered subject, but needs the growths to be well ripened to ensure a good display of blossom.

Popular Edging Plants.—The most popular edging plants are probably to be found among the typical hardy bedding plants, under which we note Alyssums of the saxatile type, Bellis, Cheiranthus, Myosotis, Polyanthus, Primula vulgaris, etc. (Many of the subjects preceding can also be used for bedding purposes.)

Bulbs, though out of the range of this article, are famous subjects for edgings, especially the free-flowering, dwarf-growing species and varieties, which are so largely used for rock garden planting.

Omissions.—The subject of edgings offers an immense field of study and experimental work among the Hardy Plants, and many subjects are perforce omitted from the foregoing notes which would make pleasing edging plants.

Among these one may note *Alyssum maritimum, Caltha palustris flore pleno* (damp places), *Coreopsis lanceolata, Linums* (such as *flavum, narbonense*, and *perenne*), *Pyrethrum hybridum, Trollius, Scabiosa caucasica*, and the dwarfer perennial *Statices*.—P. S. H.

EDGING IRONS.—See *Garden Tools*.

EDGING PLANTS, Half-Hardy.

Half-Hardy Annuals.

Ageratums (in variety).
Asters (in variety).
Balsams (in variety).
Lobelias (dwarf).
Nasturtiums (dwarf).
Nemesias.
Petunias (in variety).
Phlox Drummondii (in variety), etc.
Portulacas (in variety).
Sedum coeruleum (in variety).

Half-Hardy Perennials.

Antirrhinums [1] (dwarf varieties).
Antirrhinums (intermediate varieties).
Begonias (Tuberous).
Begonias (Fibrous).
Echeverias (in variety).
Geraniums (Ivy).
Geraniums (Zonal).
Heliotrope (in variety).
Mesembryanthemum (in variety).
Salvias (in variety).
Verbenas, etc. P. S. H.

EDGING: Rock Plants for.—Some are included in our article on *Edging: Hardy Plants for*. Also see Rock Plants for Edging in *Rock Plants for All Purposes*.

EDIBLE FUNGI.—See *Fungi: Edible and Harmful*.

EDRAIANTHUS.—A synonym for *Wahlenbergia*, which see.

EDUCATION AND GARDENING.

Does a gardener need to be specially educated? We say emphatically "Yes." The man in the street usually says "No." It must, however, be evident that whereas an uneducated lad frequently drifts into a mere "hewer of wood and drawer of water," the one who literally "knows his book" almost automatically passes into the less laborious, but more interesting and better remunerated positions. Even such manual work as digging can be performed more easily, and certainly with greater interest, if the worker is able to apply the elements of mechanism to it. The value of work done does not necessarily depend upon the amount of muscular energy expended, but upon its utility. Ground does not usually require digging in March in the same way as in November. It is necessary to determine what is desired,

[1] Antirrhinums are listed as Half-Hardy subjects; but ofttimes they may almost be regarded as Hardy Plants.

and the means of thorough accomplishment with the minimum fatigue. To obtain such results a really good education for the organiser is indispensable, and the labourer should have, at least, a rational one.

We do not mean that a College education is essential for a successful gardener. Why should it be? College courses are designed for organised progress. Examination honours are obtained with comparative ease by College students, and together with the almost certain influence of the "Powers that be," give such students immense starting advantages in the race for positions. Discussions with other students are invaluable. Innumerable difficulties crop up which questions and answers from a good instructor would quickly clear. For these reasons youth should, if possible, avail himself or herself of the many scholarships now offered to study at one of the Colleges.

Self-education is likely to be less well directed. Time is lost through not making a good selection of subjects, or properly allotting time to the study of each. The self-educated student also lacks the training requisite suitably to marshal his knowledge to please examiners. This, however, he can to a large extent get over by correspondence. Finally, the self-educated student has to compete against the influence of "Friends at Court," as College authorities frequently are. Justice to others is not always sufficiently pronounced to outweigh a natural prejudice in favour of a personal friend. On the other hand, a lad who cannot go to College, but has a persevering determination "to win through," and well arranges his studies, making the utmost of his time and abilities, may reasonably hope to succeed ultimately. The chances of giving up in despair are great, but the certainty of a glorious triumph is assured if he persistently pursues his upward course. Indeed, having been successful through the "Mill of Difficulties," he is the man who will make his mark. The world wants independent thinkers, who will later bring their life's experiences into hotch-potch. The co-operation of even a few really good self-educated persons will beneficially leaven large numbers of College-trained individuals, who have necessarily followed more or less in the prescribed groove.

Avoid Specialising.—A self-educated youth must take the utmost care not to specialise too soon. There is very great danger that he will do so, for he may become particularly interested in one thing, as, for instance, hybridising, and he reads all available books on the subject, and probably devotes much time to investigations. That is time wasted, however, as he cannot understand or appreciate fully what has been written upon the subject, nor can he winnow away the chaff from the grain of what is available. Time will be lost in doing work which a wider knowledge would show to be useless, and in any case such early specialisation will make him a very narrow or one-sided person. A thoroughly good elementary education is essential before studying any special branch of gardening. Theoretically the average lad has had a good grounding before leaving school, but experience shows that comparatively few can write a decent business letter, and still fewer can make simple calculations involving a practical knowledge of arithmetic and mensuration. Young men who have obtained high standards at school, have been quite at a loss to calculate the number of plants required for a triangular-shaped piece of ground upon which they may be standing, or to determine the approximate time and cost likely to be involved in any particular purpose. Yet such calculations can be made extremely interesting, and the usefulness is beyond words. We urge all intending gardeners to lose no time in setting to work to acquire the ability to do such things with alacrity.

What to Study.—Given a good preliminary education, what are the special subjects essential for a gardener? Naturally we must first mention BOTANY, the science which, in its widest sense, teaches all about plants. The old idea of this science was that it had largely to do with difficult names, and classification figured as the most important part of Botany; but we now rightly recognise the importance of structure and function. Indeed, so well is the importance of function now recognised, that it is sometimes considered almost a separate subject, and volumes have been written upon it under the name of *Plant Physiology*. Readers should study the article on this interesting branch of Botany which is given elsewhere in these pages. Obviously the structure of plants should be studied in conjunction with function. The raiser of new

varieties, and even the grower of seeds, must know all that can be learnt of the alliances of his plants. A few years ago we heard the generally excellent gardener of a well-known public personage describing his endeavours to obtain a cross between the red currant and tomato! Doubtless there have been many similar futile attempts made by those who might easily have utilised their energy with advantage. However, even the most expert may wisely refrain from expressing contempt for honest endeavours. It does occasionally happen that some unrecognised force greatly modifies expected results, and it is true that in "Nature's infinite Book of Secrecy" a very little can yet be read. Knowledge of proved facts is needed; this, combined with the ability and trained alertness to observe any unexpected variation is what is needed, and the aim and object of education.

Many gardeners have very vague ideas respecting the important science of CHEMISTRY. It has been defined by schoolboys as "the science of explosions," because by carelessly mixing wrong chemicals there is likely to be an abundance of broken glass flying about. To some persons the chemist is a person who makes filthy smells in a laboratory, or mixes materials for the purpose of blowing the roof off; to others he is merely a dispenser of pills and disgusting tasting physic in a shop. The chemistry which is of such immense use to a gardener is, however, of a very different type, dealing as it does with the composition of soils, manures, and plants, also with insecticides and fungicides. The changes undergone in soils as the result of tillage operations, how to feed plants for any particular purpose, are also among the facts which chemistry teaches a gardener. The gardener needs to know the circumstances in which he can safely, and with advantage, use nitrate of soda or sulphate of ammonia; when he should use basic slag, and when superphosphate or bones as a source of phosphate. He should know what fertilisers he can safely mix; and what should be studiously avoided. This was forcibly shown by an incident which occurred a short time ago. An organiser knew that he needed for various crops both nitrogen and phosphates. He purchased sulphate of ammonia for his nitrogen, and basic slag for his phosphates, and on leaving home one morning ordered his men to mix these thoroughly! The escaping ammonia was so overpowering that the mixers had to spend most of their time outside the shed. By making frantic dashes to do a little mixing they were able to execute their orders, and therefore rendered two valuable substances well-nigh useless by a simple mistake! Such errors have sent not a few to "that bourne from which no traveller has returned." Sound knowledge of Chemistry not only enables one to avoid such mistakes, but gives us immense power over the numerous tiny plant foes. Chemistry teaches how to destroy insect pests in thousands, and, better still, how to prevent the birth of millions. By such compounds as Bordeaux Mixture and other fungicides, plants can be safeguarded against many diseases. Rightly mixed and properly applied (which is so often not the case), the gardener can safely rest in his armchair, studying the latest news and enjoying his nicotine, assured that his plants are safely protected.

Such branches of PHYSICS as light and heat are important studies for the gardener. The management of glasshouses, and even of hotbeds, are obviously matters which he must not neglect. Ventilation, damping, and watering, a proper balancing of light and heat, are some of the many matters which this study will materially help to elucidate.

BACTERIOLOGY is a comparatively new, but tremendously important science. Countless myriads of extremely minute organisms exist in the air, water, and especially in surface soil. Of many kinds, and every imaginable function, some known as *pathogenic* are the cause of most diseases to which man and animal are liable. One of the most important of these, so far as the gardener is concerned, is the Tetanus or lock-jaw bacillus. This exists chiefly in surface soil, and its possible presence shows the desirability of promptly cleansing and disinfecting any fresh wound, however slight, which has been in contact with soil. However, most of the bacteria with which the gardener has to deal are active friends and co-workers; Nitrates, for instance, are largely formed by their aid from humus. Study of them is most necessary if cultivation is to be thoroughly successful, and the greatest possible results gained from the soil.

Besides these subjects there are others of paramount importance for

the gardener to study; for instance, mathematics, geology, zoology, entomology, and other branches of natural history. We have no space here to describe the way he should take in these subjects, but only mention them as part of a gardener's education. We may point out in conclusion that many of the points mentioned will be found dealt with more fully in other articles; for instance, Botany, Chemistry, and Geology have an article to themselves, and Mathematics finds a place in our article on *Weights and Measures*. But when we realise the large amount of ground to be covered under each of these subjects, it is obvious that in the space of a few hundred words we can hardly do justice to it. The gardener who is wise, and means to gain the advantages resulting from a thorough education, should purchase one of the many cheap and excellent primers issued on all of these subjects, if he is not so fortunate as to be able to participate in a College education.—F. J. B.

EELWORM ROT.—See under Eelworms in *Insect Pests*.

EELWORMS.—See *Insect Pests*.

EGG PLANT.—See *Salad Plants* and *Solanum*.

EGLANTINE (*Rosa rubiginosa*).—See *Rose Species*.

ELAEAGNUS.—For the best species see *Climbing and Trailing Plants*, and *Shrubs*.

ELATERIDÆ.— See Wireworms in *Insect Pests*.

ELBOWIT GRASS (*Alopecurus geniculatus*).—See *Alopecurus*.

ELDER.—See *Medicinal Herbs*, also the genus Sambucus in *Trees*.

ELECAMPANE.— See *Inula* and *Medicinal Herbs*.

ELECTRICITY IN GARDENING. The application of electricity to stimulate the growth of flowers and vegetables is still in its infancy, and although when used in the hands of experts striking results have been obtained, it is too soon to say whether it will be possible for the ordinary gardener to use electricity profitably.

ELEOCHARIS (Spike Rush. Nat. Ord. Cyperaceæ).—This is a genus of hardy bog and water plants of very little garden value. The two best known species are *E. acicularis* and *E. palustris*, both of which grow about 6 ins. high.

ELEUSINE (Crab Grass. Nat. Ord. Gramineæ).—This is a genus of hardy grasses only suitable for the wild garden. *E. aristata*, *E. coracana*, *E. indica*, and *E. stricta* are cultivated at Kew. The second species grows 1½–2 ft. in height; the others about 1 ft., or rather less.

ELK'S HORN FERN (*Platycerium alcicorne*).—See *Ferns and Fern Gardening*.

ELK-WOOD (*Magnolia tripetala*).—See *Climbing and Trailing Plants* and *Trees*.

ELLIPSE-SHAPED BEDS, Area of.—See Areas of Beds and Borders in *Arithmetic and Gardening*.

ELM.—For the best varieties see Ulmus in *Trees*.

ELODEA.—See *Water Thyme*.

ELYMUS (Lyme Grass. Nat. Ord. Gramineæ).—This is a genus of coarse-growing, hardy grasses, of no garden value, though sometimes grown in the wild garden.

E. arenarius and *E. giganteus* are probably the two best species, and grow 1–2 yds. in height. *E. europaeus*, the common Wood Barley, is coarser, and may be dispensed with.

EMBOTHRIUM.—For the best species see *Climbing and Trailing Plants* and *Shrubs*.

EMBRACING MUEHLENBECKIA (*Muehlenbeckia complexa*). — See *Climbing and Trailing Plants*.

EMILIA.—See *Tassel Flower*.

ENCHANTER'S NIGHTSHADE. — A creeping perennial weed. For means of control see Bindweed in *Weeds*. See also *Circaea*.

ENCINA or ENCENO OAK (*Quercus agrifolia*).—See *Trees*.

ENDIVE (*Cichorium Endivia*. Nat. Ord. Compositæ).—This is often grown exclusively for autumn and winter use, but where desired a summer supply may be had by

sowing the seed in April, the last sowing being made early in August. This crop prefers a warm situation, and should have plenty of manure added to the soil.

In sowing the seed, cover very lightly, and when large enough to handle, transfer the little plants to their permanent quarters, allowing 15 ins. between the rows, and about 8–12 ins. between the plants.

Being water-loving subjects plenty of moisture is essential, failing which the plants quickly run to seed. When fully grown, or a few weeks before wanted for use, place a large pot, tin, or slate over the hearts to ensure perfect blanching, or an equally good result often follows if the outer leaves are tied together in such a way as to ensure the heart of the plant being in perfect darkness. At the approach of very severe weather lift the most promising plants, and set them close together in a garden frame, giving plenty of ventilation when outside conditions are favourable.

Varieties. — Batavian, French Moss Curled, and Imperial are the varieties chiefly grown.—F. R. C.

[Digswell's Prize is also a very reliable variety.—EDITOR.]

ENKIANTHUS.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

ENZYMES.—See under FERMENTS in *GERMINATION OF SEEDS*, and under FOOD STORAGE AND DIGESTION in *PLANT PHYSIOLOGY*.

EPHEMERUM.—Now included in the genus *LYSIMACHIA*.

EPICATTLEYA.—See *ORCHIDS*.

EPIDENDRUM.—See *ORCHIDS*.

EPILÆLIA.—See *ORCHIDS*.

EPILOBIUM (WILLOW HERB. Nat. Ord. Onagraceæ).—This is a large genus of hardy herbaceous perennials, the dwarfer species of which may be used in the rock garden or rock border, while *E. angustifolium* is useful in the water garden. (See article on *WATER GARDEN: PLANTS FOR THE*, under WILLOW HERB.) They are easily grown in light, rich loam, and may be increased by summer-sown seeds or division of the roots in the spring, which last is the best time for planting.

What to Grow.—We cannot attempt to mention more than a few of the best of the species which have been described. Those given below, however, include some of the very best :—

Epilobium alpestre.—Syn. *E. trigonum*, which see.

E. angustifolium (ROSE BAY).—This is a useful purple or rosy-crimson sort, flowering in July, and growing about 4–6 ft. in height. Its variety *album* is white.

E. angustissimum.—Syn. *E. Dodonaei*, below.

E. Dodonaei (Syns. *E. angustissimum* and *E. Fleischeri*).—This is a useful purple sort, blooming from June to July, and growing about 2 ft. high.

E. Fleischeri.—Syn. *E. Dodonaei*, above.

E. hirsutum.—This goes by the curious name of CODLINS AND

CREAM, and does best in a moist border or in the water garden. It bears purplish flowers from July onwards, and averages 4 ft. in height.

E. longipes.—Syn. *E. pedunculare*, below.

E. obcordatum.—This is a pretty trailing species, with rose-purple flowers in the autumn, and about 6 ins. high.

E. pedunculare (Syn. *E. longipes*).—This is a dwarf-growing, prostrate species, with white, pink, or rose flowers in July.

E. trigonum (Syn. *E. alpestre*).—This bears rosy-pink flowers in July, and averages about 1½ ft. in height.

EPIMEDIUM (BARRENWORT. Nat. Ord. Berberidaceæ).—This is a genus of beautiful dwarf foliage plants, which bear attractive flowers as well. Most species are easily grown in a half-shady position in sandy loam to which some peat has been added, and are propagated by division of the roots in autumn or spring. All those described below are suitable in the rock garden :—

Epimedium alpinum.—This has evergreen leaves. Flowers crimson and yellow. Flowering Period, May to July. Height, 9 ins.

E. macranthum.—The leaves of this are beautifully tinted. Flowers white, with long spurs. Flowering Period, May to July. Height, 6 ins. The variety *violaceum* has violet-coloured flowers.

E. musschianum (Syn. *E. niveum*).—This produces white flowers from May to July. Height, 6 ins.

E. pinnatum.—This is a handsome, strong-growing species, with large pinnate foliage. Flowers bright yellow, in long racemes. Site, shade. Soil ordinary loam. Flowering Period, May to July. Height, 1–2 ft.

E. rubrum.—This has beautiful tinted foliage in autumn. Flowers bright crimson and pale yellow. Site, shade. Soil, loam. Flowering Period, May to July. Height, 1 ft.

EPIPACTIS.—For the best species see *HARDY ORCHIDS*.

EPIPHERONITIS.—See *ORCHIDS*.

EPIPHYTIC ORCHIDS.—See *ORCHIDS : POTTING AND WATERING OF*.

EPSOM SALTS (*Magnesium Sulphate*). See *MAGNESIA AND MAGNESIUM COMPOUNDS*.

EQUESTRIAN STAR.—See *HIPPEASTRUM*.

ERAGROSTIS (LOVE GRASS. Nat. Ord. Gramineæ).—This is a large genus of hardy or tender grasses of very easy culture. The best species is described in our article on *ORNAMENTAL GRASSES*.

ERANTHIS (WINTER ACONITE. Nat. Ord. Ranunculaceæ).—A low growing, hardy, tuberous plant flowering very early. It thrives in any shady place, and is propagated by division in the winter.

Eranthis hyemalis.—Leaves in tufts from tubers. Flowers yellow surrounded by frill of leaflets. Soil loam. Flowering Period, January to March. Height, 3 ins.

ERCILLA.—For the best species see *CLIMBING AND TRAILING PLANTS*.

EREMOGONE.—Now included in the genus *ARENARIA*.

EREMOSTACHYS (Nat. Ord. Labiatæ).—This is a genus of hardy herbaceous plants for the perennial parterre. It is easily propagated by seeds or root-cuttings in the usual way, and thrives in ordinary light loam. The best species is *E. laciniata*, and its varieties *flava* and *iberica* are both worthy of inclusion. They bear yellow and purple flowers from July to August, and average 4–6 ft. in height.

EREMURUS (Nat. Ord. Liliaceæ). This, known also as the FOX-TAIL LILY or GIANT ASPHODEL, is a tall,

stately plant, bearing a long spike of pink, white, or yellow flowers. It is hardy except in the coldest and bleakest parts of the United Kingdom. Of late years numerous hybrids have been raised. There is still a great opening for workers in this genus: first, to get more flowers open at once; and secondly, to produce a greater range of colour. In warm summers seed is freely produced.

Culture.—The roots of Eremuri are like giant starfishes, so it is not easy to send them about. They need very careful handling, as they are easily broken. Plant them 6–9 ins. deep in good rich, well-drained soil, any time from October to March. They need an annual top-dressing with light, rich compost, unless the plants are to deteriorate, as the new bud, which contains the flower spike, is produced on the top of the previous year's bud. In cold localities a winter covering of leaf-mould or cocoanut fibre is essential. Eremuri are grateful for a little overhead shade, and if possible the young growth should be protected in spring on frosty nights, removing the covering in the daytime. Seed may be sown under glass as soon as it is ripe, the young seedlings being pricked out into a cold frame, where they should remain for a year, after which they can be transferred to an open border, though they should be protected from frost until well established. All Eremuri dislike being disturbed.

What to Grow.—*Eremurus Bungei* produces yellow flowers in spikes in July, and is 2–4 ft. high. *Pallidus* (primrose), and *superbus* (clear yellow), are two good sub-varieties.

E. himalaicus bears white spikes from June onwards. Height, 6–8 ft.

E. Olgae bears white flowers marked with red, or shaded pink, and blooms in late July; its spike is 6 ft. high. *Roseus* is a charming rose-pink sub-variety, as also are *Shelford* (coppery-yellow), and *St. Michael* (buff and pink).

E. robustus produces immense spikes of rosy-pink flowers, and grows 8–10 ft. high. *Elwesianus* (pink) and *elwesianus albus* are two fine hybrids of this, full of charm, and of great vigour. All three flower in May and June.

J. J. & E. T. E.

ERICA.—See *HEATHS* and *SHRUBS*.

ERIGERON (FLEABANE. Nat. Ord. Compositæ).—This genus, chiefly of hardy herbaceous perennials, now includes other genera, such as *Stenactis*, and is most useful as a hardy border flower, as a beginner's plant, and as a subject for town gardens. It is of very easy culture, thriving under the usual treatment given to hardy perennials, and is most useful for cutting. In the case of the dwarf sorts, success may be obtained by treating as rock plants. All the species are readily raised from seeds sown in the usual way in the summer, or they may be propagated by root division in the autumn or March, which month is a suitable planting period.

What to Grow.—A very large number of species and varieties have been described, but the following contains some of the best known and most useful sorts, omitting the annuals and biennials which are of little or no importance:—

Erigeron alpinus.—This is grand for the rock garden or rock border, and bears lavender-purple flowers in July, on plants 12 ins. high.

E. aurantiacus (ORANGE DAISY).—This is a favourite rock garden species, with orange flowers from May to July, on plants 9–12 ins. high.

E. bellidifolius (ROBIN'S PLANTAIN).—This bears purplish flowers from June to July, and averages 1½ ft. in height.

E. canadensis (HORSEWEED).—This and the last species are more suitable for the shrub border than herbaceous border. The present one is doubtfully perennial, and bears white flowers from July to August, on plants 12 ins. high.

E. Coulteri.—This is a very popular border sort, bearing white flowers from June to August, and averaging 18 ins. high. *Edina* is an improved form.

E. grandiflorus.—This is a useful purple summer blooming sort, about 2 ft. high.

E. mucronatus.—This is a gem for rockwork, bearing pretty little purple flowers in June, and averaging 6 ins. in height.

E. Roylei.—This is also good for rockwork. It bears lavender-blue flowers in July, and averages 6–12 ins. in height.

E. speciosus (FLEABANE).—This, and its variety *superba*, are quite the most popular sorts of all. They bear blue and mauve flowers from May to October, and average 2–3 ft. in height. There are many named garden varieties of this species flowering for the same period, and averaging the same height. The best of these include: *Asa Gray* (apricot); *Grandiflora* (deep purple); *La Grandesse* (mauve); and *Quakeress* (lavender-blue).

E. Villarsii.—This useful sort bears lilac-purple flowers from June to August, and averages 12 ins. in height.

NEW VARIETIES.

Erigeron B. Ladhams.—This bears rosy-pink flowers, and grows 3 ft. in height.

E. Elsie.—This bears rosy-lilac flowers with a dark eye, and grows 9–12 ins. high.

E. Pink Pearl.—This bears bright pink flowers and grows 3 ft. in height.

See also *MEDICINAL HERBS.*

ERINUS (Nat. Ord. Scrophulariaceæ).—This is a hardy evergreen rockery plant suitable for rocky crevices, old walls, and stony places. It comes up freely from self-sown seeds.

Erinus alpinus.—A small tufted species. Flowers reddish-purple. Site sunny. Soil limestone rubbish. Flowering Period, May to July. Height, 4 ins. The variety *albus* has white flowers.

ERIOCAMPA.—See under ROSE SAWFLIES and SLUGWORM in *INSECT PESTS.*

ERIOGONUM (WOOLLY KNOTWEED. Nat. Ord. Polygonaceæ).—This genus is not grown as often as it might be, but it includes some useful hardy herbaceous perennials and rock plants. It is not hard to grow provided that a light loamy soil with some peat in it is supplied; and it is propagated in the usual way by seeds sown in the spring or summer, and by division of the roots in the autumn or spring.

Perennial Border Species.—We briefly describe a few of the best below:—

Eriogonum compositum.—A yellow or sometimes white species flowering from June onwards. Height, 12–18 ins.

E. longifolium.—A species with yellowish flowers blooming from June onwards. Height, 12–18 ins.

E. tomentosum.—This also bears yellowish flowers. They open in May and continue till July. Height about 2 ft.

Rock Garden Species.—The two described below are evergreen trailing plants suitable for a rocky bank:—

Eriogonum flavum.—A tufted plant. Leaves entirely silvery. Flowers yellow in large umbels. Site sunny. Soil gritty loam. Flowering Period, July. Height, 9 ins.

E. umbellatum.—Also tufted, and spreading. Flowers golden-yellow. Site sunny. Soil gritty loam. Flowering Period, June to July. Height, 6 ins.

ERIOGYNIA.—Now included in the genus *SPIRAEA.*

ERIOPHYES.—See BIG BUD and PEAR LEAF BLISTER MITE in *INSECT PESTS.*

ERIPHILEMA.—Now included in the genus *SISYRINCHIUM.*

ERITRICHIUM (Nat. Ord. Boraginaceæ.)—This is one of the loveliest of all hardy alpines, but is difficult to grow in England. It may be raised from seed sown in spring.

Eritrichium nanum.—Leaves in woolly grey tufts. Flowers brilliant blue with a yellow eye. Site half-shade. Soil grit and sandstone. Flowering Period, May to June. Height, 2 ins.

ERODIUM (HERON'S BILL. Nat. Ord. Geraniaceæ).—This is a valuable family of perennial rock plants, many with silvery foliage, and all with attractive flowers. They thrive in sunny positions, such as on rocky ledges, and are propagated by cuttings in July or by seeds in spring. We describe the seven best species below :—

Erodium amanum.—This is a tufted plant, with sub-shrubby stems and silvery leaves. Flowers pure white. Site sunny. Soil well-drained sandy loam. Flowering Period, May to August. Height, 6 ins.

E. Chrysanthum.—This also is of tufted habit, and has very silvery leaves. Flowers lemon-yellow. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 6 ins.

E. hymenodes.—This produces hairy leaves in tufts. Flowers pink. Site sunny. Soil sandy loam. Flowering Period, May to August. Height, 1 ft.

E. macradenum.—This is a splendid hardy plant. Flowers pale violet with dark blotches. Site sunny. Soil gritty. Flowering Period, June to August. Height, 6 ins.

E. petraeum (Syn. *E. guttatum*).—This has dark green leaves. Flowers white with dark blotch. Site sunny. Soil gritty. Flowering Period, June to August. Height, 4 ins.

E. supracanum.—This has silvery leaves. Flowers pink with darker lines. Site sunny. Soil gritty. Flowering Period, April to August. Height, 3 ins.

E. trichomanefolium.—This attractive sort has silvery-grey leaves. Flowers blush-white. Site sunny. Soil gritty. Flowering Period, May to September. Height, 3 ins.

ERPETION.—Now included in the genus *VIOLA.*

ERVUM.—Now included in the genus *VICIA.*

ERYNGIUM (ERYNGO, SEA HOLLY, etc. Nat. Ord. Umbelliferæ).—Although not one of the choicest subjects, the Eryngium, or SEA HOLLY, should by no means be excluded from the hardy herbaceous border, since, if not actually beautiful, it is decidedly curious and attractive. The genus includes a large number of species, some annual, biennial, and half-hardy herbaceous perennials, but all of these, being comparatively unimportant, are excluded from the present article. It is the hardy perennial species to which attention is advisable, and we describe a selection of the best at the end of the article. Roots of some species, notably *E. campestre* and *E. maritimum*, have a medicinal

value, and are ofttimes candied. Cultivation of Eryngiums is not a matter of great difficulty. Ordinary sandy soil suits them in a sunny site, and propagation by summer sowings of seeds or autumn root division, is a simple matter, while success is assured if planting is done from October to March.

Perennial Border Species. — All those below are quite hardy, and need no protection. For many other species larger works should be consulted :—

Eryngium alpinum (ALPINE SEA HOLLY).—This bears blue flowers in July, and grows about 1½ ft. high.

E. amethystinum.—This pretty sort bears pale blue or steely-blue flowers in June and July, and grows about 3 ft. high.

E. campestre.—This is a commoner sort, bearing blue flowers about midsummer, and averaging 2 ft. high.

E. giganteum.—This tall sort, useful for shrub borders, bears blue flowers in July, and averages 4 ft. high. It is only biennial in some gardens.

E. glaciale.—This is a gem for rockwork. It bears pale blue flowers in July and August, and averages 3–6 ins. high.

E. maritimum (SEA HOLLY). — This is probably the most largely grown of all. It bears steel-blue flowers in July and August, and averages 1–2 ft. in height.

E. paniculatum.—This is an attractive white sort, flowering from June to August, and growing 1½ yds. high.

E. Serra.—This attractive white sort flowers in August and September, and grows 2 yds. high.

E. spinalba.—This spiny sort is more curious than beautiful. It bears white flowers in August and grows 12 ins. high.

E. yuccaefolium.—This has Yucca-like leaves (hence its name), and bears white flowers in August, and September, on plants nearly 2 yds. high.

ERYNGO.—See *ERYNGIUM.*

ERYSIMUM (PERENNIAL WALLFLOWER. Nat. Ord. Cruciferæ). —For bright colouring, hardiness, continuity of blooming, and easy cultivation, the ANNUAL ERYSIMUMS are hard to beat. In form of leaf and flower, and in habit of growth, they resemble the Wallflower, but the blooms are smaller, and the plants more branched. The plants are as easily raised from seeds as Mustard and Cress, and self-sown seedlings are usually plentiful if plants are allowed to ripen seeds. Although generally regarded as spring or early summer flowering subjects, Erysimums bloom practically all through the year if raised at various periods. For spring flowering in beds alone, or in association with bulbous flowers, these plants are most valuable and dependable. Seed should be sown in shallow drills in the spring or autumn, and the seedlings transferred to their permanent positions at an early stage of growth.

Erysimum arkansanum (correctly a variety of *E. aspersum*).—This is really a biennial, but is best treated as an annual in warm, sunny districts ; it bears yellow flowers throughout the spring and summer, and averages 12–13 ins. in height.

E. perofskianum.—This bears orange flowers throughout the spring and summer, and averages 12 ins. in height.

These two species, and the improved garden forms named *Golden Gem* and *Orange Gem,* are most useful subjects for spring bedding.

Rock Garden Species.—These are early flowering, Wallflower-like plants, which are propagated by division of the roots in the spring.

Erysimum kotschyanum.—This is a small tufted perennial. Flowers rich yellow. Site sunny. Soil rocky. Flowering Period, April to May. Height, 2 ins.

E. linifolium (Syn. *Cheiranthus linifolius*).—This is biennial, with tufts of narrow leaves. Flowers dark lilac. Site sunny or half-shade. Soil rocky. Flowering Period, May to August. Height, 6 ins.

E. ochroleucum (Syn. *Cheiranthus alpinus*).—This is a lovely tufted perennial plant. Flowers bright yellow. Site sunny. Soil sandy loam. Flowering Period, April to June. Height, 1 ft.

E. rupestre.—This is a spreading perennial plant. Flowers yellow. Site sunny. Soil sandy loam. Flowering Period, April to June. Height, 6 ins.—C. H. C. & W. I.

ERYTHRAEA (Nat. Ord. Gentianaceæ).—This is a small genus of pretty plants comparatively little known. The only hardy annual species worthy of note is *E. Centaurium,* a pretty native plant bearing rosy flowers in summer. It has some merit when massed in the rock garden, where it will grow 8–12 ins. high. As the COMMON CENTAURY it was formerly credited with medicinal virtues.

Perennial Border Species.—Only two are worth troubling with. These, *E. conferta* and *E. Massoni,* bear pink and rose flowers in June and July respectively, and grow 9–12 ins. high. They may be used in rock borders and require a warm, open, sunny spot, and a sandy soil. Propagation by division of the roots in the spring is the best means of increasing stock, and it is wise to delay planting till about the end of March, for the plants are not strictly hardy, requiring in exposed districts to be wintered in a frame.

ERYTHROLAENA.—Now included in the genus *CNICUS.*

ERYTHRONIUM.—See *DOG'S TOOTH VIOLETS.*

ESCALLONIA.—For the best species see *SHRUBS.*

ESCHSCHOLZIA (Nat. Ord. Papaveraceæ).—This genus is interesting horticulturally apart from the fact that it gives to our gardens a race of brilliantly flowered, easily grown plants. The name itself is one of the first a youngster is asked to spell when he enters upon a career as a gardener or seedsman, and when he has satisfied his questioner he has rarely satisfied the botanical authorities, because many of the best seed catalogues and some gardening dictionaries gave the title incorrectly as *Eschscholtzia,* though there is no warrant for the inclusion of the letter *t.* Authorities have given the generic title variously as *Eschholtzia, Eschholzia, Escholtzia Eschscholtzia,* and *Eschsholzia,* so there is some excuse for errors in orthography.

Another curious point is that Eschscholzias are almost as frequently described as perennials as annuals. From the horticultural point of view the popularly grown forms are annuals, but it would not be difficult to prove that in many places, especially in sandy places near the sea, plants may survive for two or more seasons. Only one species need be considered here, *i.e. Eschscholzia californica.* This is best sown in March or early in the autumn, in light soil and a sunny position; the seedlings being thinned out to 9 ins. apart.

Eschscholzia californica (Syns. *E. caespitosa, compacta, crocea, Douglasii, hypecoides, rosea, tenuifolia,* and *Chryseis aurea*) bears yellow, orange-centred flowers. Its leaves are slender and finely divided. By

selection the colours of the flowers have been increased, and varieties of special distinction are listed under name, and of these the following are a good selection :—*alba* (cream white); *Diana* (pale yellow and rose); *Golden West* (golden-yellow and orange); *Frilled Pink* (pink and cream, crimped flowers); *Mandarin* (orange, scarlet, and gold); *Mikado* (orange crimson); *Orange Queen* (deep orange and yellow); *Rose Cardinal* (creamy rose); *Rosy Queen* (rose and pink); and *Ruby King* (deep ruby crimson). All these are handsome summer bedding plants, and fine for providing colour in the rock garden, but a warm sunny position is essential to secure the freedom of flowering and brilliance of colouring which make Eschscholzias so strikingly effective.—C. H. C.

NEW VARIETY.

Eschscholzia The Geisha.— This bears glossy, large crimson flowers, and is in every way a first-class sort.

ESPALIER MODE OF FRUIT CULTURE.—Not so many years ago this system of growing fruit was very much more practised in all gardens, large or small, and in many older gardens there are now grand specimens of the perfect training that such trees received. For Apples and Pears it is such an excellent system that every effort should be made to encourage its popularity, since they can be planted by any path side, occupying little space, giving little trouble, but a pleasing appearance at all times, and producing good crops of the finest fruit if a few precautions are taken.

First, the soil should be well drained. Second, if the drainage and soil is not good, it should be made good before planting. Third, the position should be sunny and not shaded by trees. Fourth, the varieties need very careful selection; they should be of the best and, of course, suitable for the district. Fifth, the stocks on which they are grafted or budded are very important.

We must remember that the growth of espalier-trained trees is restricted, and that to plant trees on a rampant free-growing stock means trouble later on; the roots penetrate to a bad subsoil, and soon need root-pruning, or lifting. If they fruit, such fruit is cracked, spotted, and ruined in appearance; in fact, it is difficult to say what evils do not follow unsuitable stocks. For all trees of restricted growth the broad-leaved or English Paradise stock is the best for apples, as it gives a moderate sturdy growth; its roots do not ramble to great distances or great depths, but form a mass of fibres with a reasonable range of the stem. They can thus be fed heavily or otherwise with manure according to the crop the tree is bearing. The Crab or Free stock is first-rate for standard apple trees, but one of the worst for espalier trained ones. Another great advantage of trees worked on a stock with moderating influence on growth is, that the roots being practically close at home, can get the full benefit of solar influence, and are easily fed, and by this feeding the roots keep near the surface, and are altogether under more control than if on very robust stocks.

In many places Pears are highly esteemed, but they are not as satisfactory as they would be if they were grafted or worked on the Quince stock instead of the Pear; in fact the Quince and the Pear stocks have just as much influence on the Pear as the Broad-leaved and Crab stock have on the Apple, and the remarks are equally applicable to both.

The question of varieties is a most difficult one, as no hard and fast rules can be laid down. A variety that succeeds admirably in one village or district may be a total or partial failure in the next parish. Therefore it is advisable before going to the expense of buying and planting espaliers, to ascertain which varieties do best under restricted culture in one's own immediate neighbourhood. Almost any tree that is successfully grown as a bush, pyramid, or cordon tree, will answer very well as an espalier.

Taking half a dozen culinary Apples, the following will do well for the purpose named:—Lane's Prince Albert, September to March; Ecklinville Seedling, August to October; Newton Wonder, September to April; Rev. W. Wilks, October and November; Early Victoria, July and August; Edward VII., January to April.

Six varieties for dessert:—James Grieve, September to October; Allington Pippin, October to December; Beauty of Bath, August; Egremont Russet, October to December; King of the Pippins, September to January; King's Acre Pippin, November to March.

The finest dessert variety of all is *Cox's Orange Pippin*, but it requires a warm soil and situation; under these conditions it possesses no equal, and should be first on the list to plant, otherwise it is somewhat uncertain. Those named are not fastidious, and may be relied upon in most places.

Taking a dozen varieties of Pears in their order of ripening, the following will all be found to succeed on espalier trees where this usually answers, as they possess good constitution, fertile habit, and excellent flavour:—Doyenne d'Été, July; Souvenir du Congrès, September; Louise Bonne of Jersey, October; Durondeau, October to November; Beurré Hardy, October to November; Beurré Superfin, November; Doyenne du Comice, November to December (the finest of all pears); Glou Morceau, December to January; Winter Nelis, December to January; Josephine de Malines, December to February; President Barabe, February to March; Easter Beurré, February to March. If a stewing variety is wanted Catillac is one of the most reliable.

Peaches, nectarines, plums, cherries, and apricots are not included amongst trees for espaliers, as this style of training is quite unsuited for them in the open.—S. T. W.

ESPALIERS: PRUNING OF. — See *PRUNING FRUIT TREES*.

ETRUSCAN HONEYSUCKLE (*Lonicera etrusca*).—See *CLIMBING AND TRAILING PLANTS*.

EUCALYPTUS (AUSTRALIAN GUM TREE. Nat. Ord. Myrtaceæ).—This plant is of vigorous growth, producing a fine effect the same season from seed. Sow in heat in February or March, in good turfy loam, peat, and silver sand. Temperature needed, 40–50° F.

Greenhouse Species.—*Eucalyptus citriodora.* — White. Flowers in September. Height, 1½–4 ft.

E. coccifera.—Purple. Flowers in November. Height, 1½–6 ft.

E. cordata.—White. Flowers in July. Height, 1½–6 ft.

E. ficifolia. — Crimson. Flowers in September. Height 1½–6 ft.

E. *globulus* (BLUE GUM).—White. Flowers in July. Height, 1½–6 ft.

See also *TREES*.

EUCHARIDIUM (Nat. Ord. Onagraceæ). — This genus consists of two or three species, all from California and all quite hardy. They have neat foliage and look well when grown in masses in the

rock garden, or in beds, or as marginal subjects. An August sowing gives the best results, but March sown plants will provide flowers in late summer and autumn. Thin out to 4 ins. or 6 ins. apart.

What to Grow.—Below we describe the three best :—

E. Breweri. — Flowers sweetly scented and of pale rose colour. They are produced freely throughout the summer. Height, 6 ins.

E. concinnum.—The colour of this varies from blush to lilac-purple, and the plant blooms throughout the summer. Height, 8 ins.

E. grandiflorum is practically a large-flowered form of *E. concinnum*, but sometimes accorded specific rank.

EUCRYPHIA.—For the best species see *Climbing and Trailing Plants.*

EUDIANTHE.—Now included in the genus *Lychnis.*

EULOPHIA.—See *Orchids.*

EULOPHIELLA.—See *Orchids.*

EUNOMIA.—Now included in the genus *Æthionema.*

EUONYMUS.—For the best species see *Climbing and Trailing Plants* and *Shrubs.*

EUONYMUS MILDEW.—See *Diseases of Plants.*

EUPATORIUM (Hemp Agrimony. Nat. Ord. Compositæ).—This is a genus of useful evergreen shrubs and hardy herbaceous perennials of easy culture. The first section should be potted in peat, loam, and sand. It is propagated by cuttings in spring under frame or hand-light in little heat. Temperature required, 40–50° F.

Greenhouse Species.—*Eupatorium floribundum.* — Blue. Flowers in July. Height, 1–2 ft.

E. ianthinum.—Purple. Flowers in January. Height, 1–1½ ft.

E. odoratum.—Pink. Flowers in June. Height, 1–2 ft.

E. vernale.—White. Flowers in February. Height, 1–1½ ft.

E. weinmannianum. — White. Flowers in February. Height, 1–2 ft.

Perennial Border Species.—These are coarse, but useful subjects for the herbaceous border and shrub border. They are of very easy culture, quite hardy, and need no special comment save that ordinary good garden soil is required in a sunny site and that efficient staking is essential to success. Propagation is best effected by root division in the spring, which is also the most suitable planting period. We recommend the following :—

Eupatorium ageratoides (Syn. *E. altissimum*). — This bears white flowers in September and grows about 4 ft. in height.

E. ambiguum.—Syn. *E. serotinum*, below.

E. aromaticum (Syn. *E. cordatum*). —This is similar to *E. ageratoides*, but is aromatic and blooms in July.

E. cannabinum (Holy-rope).—This bears pink flowers from June onwards and grows about 4 ft. high.

E. cordatum.—Syn. *E. aromaticum*, above.

E. perfoliatum (Bone-set).—This is a white sort blooming from July onwards and growing 2–4 ft. high.

E. purpureum. — This and its variety *maculatum* bear pink and purple flowers respectively from July to August and grow 4–5 ft. in height.

E. serotinum (Syn. *E. ambiguum*).—This bears violet flowers in October on plants a yard in height.

EUPHORBIA (Spurge. Nat. Ord. Euphorbiaceæ).—This is a large genus of stove shrubs, greenhouse shrubs, greenhouse perennials, hardy and stove annuals, hardy or half-hardy biennials, and hardy her-

baceous perennials. To describe the culture of any of the species save those in the last section is beyond our scope. None of the species are very desirable plants, and some are very weedy. The following are, however, probably the best known species: *E. amygdaloides* (Syn. *E. sylvatica*), the WOOD SPURGE; *E. Esula*, TURBITH; *E. helioscopia*, the SUN SPURGE (see article on *WEEDS*); *E. Lathyrus*, the CAPER SPURGE, and source of the well-known CAPERS useful for flavouring purposes; *E. Peplus*, the PETTY SPURGE (see article on *WEEDS*); and *E. segetalis*, the CORN SPURGE.

Perennial Border Species.—These require the usual treatment bestowed on hardy herbaceous perennials and are of easy culture, thriving in ordinary soil in a sunny site. They may be propagated by seeds and root division in the usual way. The best species are: *E. Cyparissias*, the CYPRESS SPURGE (height, 12 ins.); *E. hyberna*, the IRISH SPURGE (height, 12 ins.); *E. palustris*, the MARSH SPURGE (height, 3–4 ft.); *E. Paralias*, the SEASIDE SPURGE (height, 12 ins.); and *E. portlandica*, the PORTLAND SPURGE (height, 9 ins.). These may be used in the perennial and rock borders, also in the shrub border and wild garden, while *E. palustris* is useful in the drier portions of the water garden.

EUPHRASIA.—See EYEBRIGHT in *MEDICINAL HERBS*.

EUPROCTIS.—See BROWN TAIL MOTH in *INSECT PESTS*.

EURHODODENDRON.

This is a group of Rhododendrons and is quite the largest. It includes most of the plants contained in our list of Rhododendron species. See article on *RHODODENDRON*.

EUROPEAN GOOSEBERRY MILDEW. See under GOOSEBERRY MILDEW, EUROPEAN, in *DISEASES OF PLANTS*.

EUROPEAN LARCH (*Larix europaea*). See *TREES*.

EURYANGIUM.—Now included in the genus *FERULA*.

EUSTACHYS.—Now included in the genus ORNITHOGALUM.

EUTOCA.—See *PHACELIA*.

EVENING PRIMROSE (*Œnothera*. Nat. Ord. Onagraceæ).—The genus includes about a hundred annual, biennial, and perennial herbs, with yellow, rose, or purple flowers. The two biennial Evening Primroses described below may be sown in the open border in June or July, and thinned or transplanted to bloom the following summer. If allowed to ripen seeds they sow themselves, and the seedlings may be transplanted to suitable places. The Perennial Border Species succeed with the usual treatment bestowed on perennials.

Annual Species.—See *GODETIA*.

Biennial Species.—These are somewhat numerous, but the two best are described below:—

Œnothera biennis.[1]—A pale yellow fragrant sort, blooming from June to September, and averaging about 2–4 ft. in height. *Œ. lamarckiana* is frequently named *Œ. biennis* var. *grandiflora*.

Œ. lamarckiana.—Also pale yellow and fragrant. The flowers are large, and are produced from June to September. The height averages 2–5 ft.

Perennial Border Species.—There is a large number of these. We have only space for a few of the best, and those named below are all quite hardy:—

Œnothera anisoloba.—A white sort, changing to red, flowering in June, and averaging about half a yard in height.

Œ. Fraseri.—A yellow sort similar

1 This is the COMMON EVENING PRIMROSE.—EDITOR.

to *Œ. glauca*, of which it is by some considered a variety.

Œ. fruticosa.—Probably the most popular of the perennial kinds. This sort bears yellow flowers from June to August, and averages 1–3 ft. in height.

Œ. glauca.—This also is yellow, and blooms from June to August. Its height is 1½–2 ft.

Œ. macrocarpa.—This sort is often offered by nurserymen. It is synonymous with *Œ. missouriensis*. See ROCK GARDEN SPECIES below.

Œ. Nuttallii.—A white sort blooming in June and July. Height about 1 ft.

Œ. Sellowii.—A yellow July blooming sort about 2 ft. high.

Œ. serotina.—A yellow late-flowering sort coming in during September, averaging half a yard high.

Œ. speciosa.—This, described below, is suitable for the perennial border.

Œ. Youngii.—A yellow sort flowering from June to September, and averaging half a yard or more in height. Probably a form of *Œ. fruticosa*.

Rock Garden Species. — Four species are suitable for the rock garden. They thrive in sunny, well-drained situations, and are propagated by seeds sown in gentle heat in March.

Œnothera acaulis (Syn. *Œ. taraxacifolia*).—This produces Dandelion-like leaves in tufts. Flowers white, fading to pink, very large. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 6 ins.

Œ. caespitosa (Syns. *Œ. marginata* and *Œ. eximia*).—A spreading species sending up tufts of hoary leaves. Flowers white, 4–6 ins. across, and sweetly scented. Site sunny. Soil sandy loam. Flowering Period, May to June. Height, 9 ins.

Œ. missouriensis (Syn. *Œ. macrocarpa*).—Tufts of silky leaves and prostrate stems are produced by this plant. Flowers yellow. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 6 ins. or more.

Œ. speciosa.—A sub-shrubby species with slender wiry stems. Flowers pure white to rose, and sweetly scented. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 2 ft.

See also *GODETIA*.

EVERGREEN VIRGINIA CREEPER (*Vitis striata*).—See *CLIMBING AND TRAILING PLANTS*.

EVERGREENS.

The term evergreen applies to all subjects which retain their leaves or foliage in a green state from one year's end to another. It not only applies to shrubs, to which the term is most often applied, but also to numerous trees, many rock plants, and some few hardy perennials. Evergreens are quite indispensable in gardens of all sizes, and even the smallest villa residence is proud to possess a few of them. When shrubs are not evergreens they are said to be *Deciduous*—that is, they lose one year's leaves at the fall instead of retaining them until after the new leaves have opened. The shrubs described in our article *FLOWERING SHRUBS* belong to both classes, and all should be grown where space permits. Under *SHRUBS* and *TREES* we give extensive lists of

these subjects and distinguish those which are evergreen by the letter *E*. As a rule evergreens are of easy culture, thriving with but little care. The general hints in our article *Shrubberies: Management of*, should be useful to the reader in this connection, and hints on the pruning of these subjects will be found in our article *Pruning Roses and Shrubs*.

See also *Flowering Shrubs*, *Shrubs*, and *Trees*.

EVERLASTING FLOWERS.

None of the flowers that we grow are in the true sense of the word "everlasting," and when this descriptive word is used horticulturally it is generally in a comparative sense. Several genera (mostly belonging to the natural order Compositæ) produce flowers of a tough papery consistency, which if gathered and hung downwards in a dry, clean place before they are fully expanded will dry well, and retain their form and colour for a long time if placed in dry vases, after their stems have been hardened by the drying process.

All the classes of plants referred to in the following notes are best treated as half-hardy annuals. They should thus be sown in the usual way in gentle heat during February or March, after which pricking out and hardening off follow prior to planting out of doors.

Acroclinium roseum.—See *Helipterum roseum*, below.

Ammobium (Everlasting Sunflower).—*A. alatum*, the Winged Everlasting, and its variety *grandiflorum* bear yellow and white flowers from June to August, on plants 1–2 ft. high. The latter is the larger and finer variety. *A. plantagineum* bears white flowers about the same time, but rarely exceeds 18 ins. in height.

Athanasia annua.—See *Lonas inodora*, below.

Gnaphalium obtusifolium.—This is a yellow July flowering plant about 12 ins. high.

Helichrysum (Everlasting Flower).—*H. bracteatum* is the principal species and is an attractive subject blooming from July to September, and growing 1–3 ft. high. There are numerous varieties offered by seedsmen, and the flowers may be white, rose-pink, red, clear yellow, or golden-yellow. The sorts named *monstrosum* and *nanum* are probably the best on the market.

Helipterum.—This Australian genus is sometimes known by the name of Immortelle, but this popular name belongs more to *Xeranthemum*, to be described directly. *H. humboldtianum* (Syn. *H. Sandfordii*) bears yellow flowers from June onwards and averages 1½ ft. in height. *H. Manglesii* (Syn. *Rhodanthe Manglesii*), is a charming plant for pot culture in the conservatory or for house decoration. It bears rose-coloured flowers from June onwards, and grows 1 ft. high. It may be sown out of doors in April, in a sunny site, and the seedlings thinned to 2–3 ins. apart each way. *H. roseum* (Syn. *Acroclinium roseum*), a pretty subject, bears rose-coloured flowers from June onwards, and averages 1–2 ft. in height.

Lonas inodora (Syn. *Athanasia annua*) bears yellow flowers from July onwards, and averages 1 ft. in height. A distance of not less than 6 ins. should be left between each plant.

Rhodanthe Manglesii. (Syn. *R. maculatum*).—See *Helipterum Manglesii*, above.

Waitzia aurea.—This bears golden yellow flowers in the late summer, and averages 18 ins. in height.

Xeranthemum (IMMORTELLE).—This is a very popular everlasting flower, especially abroad, where, when dyed and dried, it is used for wreath-making. If the flowers are cut when just opening and hung downwards in a dry shed for a time they will last for a long period and may be used for room decoration. The best species are: *X. annuum* (purple); *X. cylindraceum* (white); *X. erectum* (white); *X. inapertum* (purple); and *X. longepapposum* (white); all of which bloom from July onwards, and average 9–12 ins. in height.

C. H. C.

See also *HELICHRYSUM*.

EVERLASTING PEA (*Lathyrus latifolius*).—See *CLIMBING AND TRAILING PLANTS*.

EVERLASTING SUNFLOWER.—See AMMOBIUM in *EVERLASTING FLOWERS*.

EXACUM.—See *ANNUALS, HALF-HARDY: LIST OF*.

EXARRHENA.—Now included in the genus MYOSOTIS.

EXETER ELM (*Ulmus montana fastigiata*).—See *TREES*.

EXHIBITING FLOWERS.

The amateur floriculturist who grows flowers for exhibition would be distinctly displeased with the Editor and the staff of BLACK'S GARDENING DICTIONARY if an article, although short, was not included on the matter of exhibiting flowers, and although we are unable to give the lengthy dissertation upon this subject that some readers would wish, we are quite willing to spare a little space for a few practical hints on this all-important interesting topic.

As a judge who has officially attended many shows, the present writer wishes first of all to draw the attention of exhibitors to the frequent irresponsible mistakes which they make. For instance, the schedule provides that four Dahlias of one variety shall be exhibited, and the exhibitor and would-be prize-winner finds that he has five uniform blooms, so instead of devoting his vases or glasses to the four best he puts five flowers in, and thus has to be immediately disqualified. Similar mistakes are found in bouquets of flowers. In a recent show attended by the writer the schedule specified that twelve different species of flowers were to form one bouquet. Competitors in this class failed to grasp the meaning of the term twelve different species. Some put fourteen, some as many as twenty, and some put only eight different flowers. The Secretary was approached on this matter to see whether any inquiries as to the exact meaning of the term Twelve Species had been made, but competitors, instead of asking, had concluded that their own reading of the term was correct.

The first thing that judges do in the show tent is to read the rules which govern the show. Now, long experience enables most judges to grasp in a very few minutes the salient points of these regulations, and one of the first things they do is to weed out any exhibits which are too poor to consider and which are irregular in character. The first needs no comment, but the irregularities in exhibits which are so common need a word or two of attention. A man, for instance, enters a class for twelve blooms of one variety of any flower, for instance the Dahlia. He finds he has twelve of uniform and moderate size, which are of good shape and of unblemished character. Then just as he is going to the show he sees that he has three much bigger blooms uncut. Temptation immediately assails him, and he falls a victim. He removes three of the

uniform good-sized blooms and puts in the three much larger ones, thinking that he will be certain to win the prize this way. The judges arrive. They see this one-sided, ungainly exhibit, and they weed it out. The man who has twelve blooms of uniform size is awarded the prize.

A frequent source of annoyance to judges and disappointment to exhibitors is the fact that those who show do not label their exhibits correctly. Exhibitors do not seem able to grasp the simple instructions in the schedules; their exhibits often get hopelessly mixed up with other classes, and frequently when one man is exhibiting in three or four different sections or classes he will put three or four varieties of flowers together when only one is allowable. Much waste of the judges' time could be avoided if every exhibitor would read his rules first, and would assure himself that his exhibit was correctly staged. Unless the schedule distinctly specifies to the contrary, it is assumed that one exhibit must contain only one variety of any one florists' flower classed as such.

General Hints.—In conclusion we will give a few general hints to exhibitors of flowers.

(*a*) Cut your best flowers so long as they are of uniform size.

(*b*) Never put in a blemished flower among unblemished ones. If you have not a perfect bloom of any given size, substitute a perfect specimen of as near that size as possible, rather than put in one that is fading or gone to seed.

(*c*) Water all flowers intended for exhibition the night before, and be certain to give them a good soaking.

(*d*) Apply no stimulants to flowers required for exhibition on the night before the exhibition, since, unless great care is exercised, they may be spoiled at the last moment.

(*e*) Cut your flowers in the early morning while the dew is still on them, where possible. Take them immediately into the cellar, or put them in water in any similar cool place.

(*f*) Cut your flowers with as long stems as possible, since you can easily shorten them if necessary in the show tent.

(*g*) Take a few extra blooms to the show tent with you in case some may be damaged or be found defective when arranging the exhibits.

(*h*) Pack your flowers for transit with great care in damp moss, keeping the ends of the stems to one end with extra moisture, or they may suffer if they have to travel far on a hot day.

(*i*) Use a little phosphate of ammonia, say a quarter of an ounce to the gallon of water, a day or two before the show if your flowers are not sufficiently open for the purpose of exhibition.

(*j*) Use a little gum arabic dissolved in water for fixing the petals of such flowers as Pelargoniums should they open too soon, unless your schedule specifies to the contrary.

(*k*) Lastly, arrive at the show tent by the time specified in the schedule, and complete your exhibit as early as possible. Amateurs are unaware of the time it takes up to set three or four exhibits, but judges know to their cost how excessively aggravating it is to be unable to start their work by the advertised time. The result is that they have to hurry it, on account of exhibitors being still in the tent, and not leaving time to do the work properly.—E.

EXHIBITING FRUIT.

It is unnecessary to give details of this work here as fruit is but seldom exhibited by beginners, and fruit shows are usually few and far between. The general rules described in our

article on *Exhibition Vegetables* hold good for fruit also, and chapters concerning this work are given for the benefit of those who wish to specialise in this direction, in the larger works on fruit growing.

EXHIBITING SWEET PEAS. — See *Sweet Peas.*

EXHIBITION, Roses for.—See under Roses for Exhibition in *Roses for All Purposes.*

EXHIBITION VEGETABLES.

The growing, raising, and exhibiting of vegetables is an art in which success is attained, not by any collection of carefully preserved secrets, but rather by diligence, care, tenacity, forethought, and, in a lesser degree, by the results of experience. All those who grow for home consumption should set the exhibition standard before themselves as the model to work from, and when they reach a perfection with which they feel confident successful exhibiting could be done, if so inclined, then is the time for making the first attempt at what always proves a fascinating task. Before doing this they will discover that the vegetables grown up to the standard aimed at are far more profitable than the rough and ready grown specimens.

Having raised the exhibition article, do not hesitate to show it, even though success is unlikely at the first attempt or two; for it is at this juncture that much of the experience previously referred to will be gained, and for the persevering exhibitor success will be born of preliminary failure. The writer well remembers his first attempt at a large exhibition. After a number of local successes, the inspiration came to attempt something bigger, and the necessary steps were taken. Came the day of the show, and the young enthusiast, allowing what he considered ample time for staging, arrived at the venue of the show, only to find that the older and wiser men had already set up their exhibits. The result was a rush to get the exhibit up, and the final accomplishment was to find oneself classed only fifth in the order of merit. Gain number one had, however, accrued, and the following year, allowing far more time for setting up, the writer discovered himself, after the judging, amongst the first three; and, still profiting by what he learned, had the proud position the following year of finding himself classed number one in the company of the leading growers and exhibitors in the country. Thus one learns by experience, and the first precept I would set for the intending exhibitor is to learn all he can from the old hands of the game.

This is not all, however, for to be a successful exhibitor one has many things to study carefully in the cultivation of vegetables. One must know the soil, what it is capable of producing, what treatment it requires, and what addition it is necessary to add in the form of manure, etc. etc., and this can only be known from the result of keen and steady observation.

Next, one must seek exact knowledge of the varieties to be grown, in the direction of time required to obtain vegetables at the point of highest perfection; for one variety of a kind will arrive at maturity far quicker than another, and this is a point especially required to be known when one is aiming at growing for exhibition on a certain date. Where more than one show is to be visited, then another matter to consider and master is a succession of supplies; and furthermore, the feeding and watering of the crops require much study and attention. Perfection is the point aimed at,

and this is where the qualities of diligence, care, etc., are required in the application of study, and though it may appear at first sight a formidable task, yet all these matters lighten as one gains more and more experience, until it becomes almost a second nature to know exactly what has to be done.

The standard of excellence which should be aimed at in an exhibit comprises several parts. One must spare no effort to attain excellence of quality combined with fineness of shape, freeness from blemish, and, lastly, size. Of the latter attribute much could be said, but here it will suffice to warn would-be exhibitors against procuring largeness of their specimens at the expense of the quality thereof.

Ideals to Aim at in some of the principal vegetables are given below:

Beetroot.—The best varieties only should be exhibited, and it matters not, in our opinion, whether they are of a very dark colour or a deep blood-red. The roots should be of medium size, perfect in shape, and without any blemish.

Brussels Sprouts.—Aim at small, perfectly firm buttons of a dark green colour and as nearly alike as possible.

Cabbage.—Medium size, conical in shape, firm heads, and free from marks of caterpillars, etc.

Carrots.—Let these be medium-sized, free from blemish, no green at the crowns, symmetrical in shape, and of a deep red colour.

Cauliflowers.—These should be perfectly fresh, of medium size, the curds not cracked, and as white as possible.

Celery.—This should be quite solid, with no trace of prematurely running to flower, perfectly blanched, and not marked by being eaten by slugs, etc.

Cucumbers.—A brace of these should be as nearly alike as possible, quite young, of medium size, perfectly straight, not rubbed, and the two old blooms should be retained on the ends of the fruit.

Leeks.—These should be of large size, long length of blanch (from 16–18 ins.), no trace of bulbing at the bottom, and perfectly clean.

Onions.—These should be well ripened, of perfect shape, quite solid, and as large as possible.

Parsnips.—Perfect shape should be aimed at, of medium size, and without blemish of any kind.

Peas.—Large pods perfectly filled, not too old, and the pods should show no signs of having been rubbed.

Runner and French Beans.—Providing these are young and the pods will snap easily without any strings, these can hardly be too long, but the point to aim at is to have the pods as nearly alike as possible as regards size.

Tomatoes.—One of the most important dishes. These should be as nearly alike as possible, of good colour, perfect in shape, quite ripe but solid, and of medium and uniform size.

Turnips.—Medium size, quite young and free from blemish, with small tap roots.

No varieties of vegetables should be exhibited which are not considered to be of first-rate table quality, as all good judges should take this into serious consideration.

General Hints.—Before packing one's exhibit for transport to the site of the show, it is very essential to have carefully read all the clauses of the schedule relating to the class in which it is to be shown, as well as all the general rules affecting it. Of these a careful mental note should be made, and every precaution taken that the exhibit does not break any of these rules, otherwise

the result may mean a disqualified exhibit.

When preparing the items, each specimen should be handled as a precious object, and all prepared as far as ever possible beforehand. All root vegetables should be very carefully sponged clean in clear cold water, and those carrying rootlets should have these carefully removed with a sharp knife, leaving the main tap root straight and unbroken. The crowns of such vegetables as Beetroot, Carrots, Parsnips, Turnips, etc., should be carefully trimmed back, and any damaged or decayed leaves removed. Cucumbers, Peas, Tomatoes, or any vegetables bearing bloom should be most gently and carefully handled, so that they do not get marked and the bloom disturbed.

The packing should, where possible, be done by the exhibitor, or at any rate under his careful supervision, so that there is no risk of damage during transit, or of anything being left out. Trays and stands should be gone over to make sure they are all in good order and ready for use at the show, and it is advisable to draw up a list of all that is to be taken to the show for exhibition in the way of the exhibit, so that one can work to it and know everything is *au fait*. Another point of importance is either to travel with the exhibit oneself, or send it in the charge of a really reliable person in whom one has full confidence, in order to guard against any of it going astray *en route*. In arranging for a collection of vegetables, one or two extra dishes should always be taken, as it frequently happens one's opponent may have a very superior dish of some particular kind or variety which it is intended to stage, whereas by substituting some other dish it may equalise or even reap higher points, as I have known many a case where there has only been a margin of half a point between the competitors.

A good supply of fresh green parsley should always be available when staging for setting up dishes of vegetables, and when putting up make the dishes look as artistic as possible. Very pleasing effects can result, especially in large collections, where care is taken in contrasting and distributing colours, and where equal merit rests between two competitors' exhibits, then the artistic and careful arrangement must finally count.—Ed. B.

EXHIBITION VIOLAS.—See *Viola*.

EXHIBITORS' GUM.

Exhibitors often require a gum for "fixing" the petals of the flowers they show, and while various kinds of so-called Floral Gum are on the market, the material is easily made at home and is then very inexpensive. To do so get a pound of pure gum arabic from a chemist or drysalter, and slowly dissolve this in a gallon of water, or rather less if a strong gum is required. Store in well-corked bottles and apply with a small camel-hair brush.

EXOCHORDA.— For the best species see *Shrubs*.

EXOGONIUM.— Now included in the genus *Ipomoea*.

EXPERIMENTS.— See *Garden Experiments*.

EYEBRIGHT. — See *Medicinal Herbs*.

F

FABA.—Now included in the genus *VICIA*.

FABIANA.—For the best species see *SHRUBS*.

FACCHINIA.—Now included in the genus *ARENARIA*.

FAGOPYRUM (Nat. Ord. Polygonaceæ).—This is a genus of hardy annual plants easily grown in ordinary soil if sown in March or April. *F. cymosum* is known as BEECH WHEAT; *F. esculentum* is the well-known BUCKWHEAT used abroad as a vegetable, and in this country for feeding stock. This must not be confused with the BUCK BEAN or BOG BEAN mentioned in our articles on *MENYANTHES* and *MEDICINAL HERBS*. The above two species bear pink flowers from July to August, and grow 2–3 ft. high.

FAIR MAIDS OF FRANCE (*Ranunculus aconitifolius*). — See *RANUNCULUS: PERENNIAL BORDER SPECIES*.

FAIRIES' WAND.—A name applied to the genus *GALAX*, which see.

FAIRY RINGS.—See *DISEASES OF PLANTS* and *WEEDS*.

FAIRY ROSE (*Rosa indica minima*).—See *ROSE SPECIES*.

FALSE ACACIA (*Robinia Pseudacacia*). See *TREES*.

FALSE ASPHODEL (*Tofieldia*. Nat. Ord. Liliaceæ).—This must be carefully distinguished from the true plant of this name which we describe in our article on *ASPHODEL*, as it belongs to quite a distinct genus though to the same natural order (*Liliaceæ*). Our present plant is one of very easy culture provided a light loamy or, better still, peaty soil and a moist site are afforded it. Like the true Asphodel it is a hardy herbaceous perennial useful for the border, and may also be planted in the wild garden or in the rock garden. It may be propagated by root division in the usual way in the spring, which is also the best planting period.

What to Grow.—We recommend the following:—

Tofieldia alpina.—Syn. *T. calyculata*, which see.

T. borealis.—Syn. *T. palustris*, which see.

T. calyculata (Syn. *T. alpina*).—This is a white sort blooming in July, and growing 6 ins. high.

T. glutinosa is similar to *T. calyculata* in all its characters.

T. palustris (Syn. *T. borealis*).—This is the well-known SCOTCH ASPHODEL bearing white flowers in May or June, and growing 6 ins. high.

FALSE AZALEA.—See *AZALEASTRUM*.

FALSE BROME-GRASS.—See *BRACHYPODIUM*.

FALSE CATERPILLARS.—See under CURRANT AND GOOSEBERRY SAWFLIES in *INSECT PESTS*.

FALSE DAISY.—See *BELLIUM*.

FALSE DICTAMNUS, or FALSE DITTANY (*Ballota Pseudo-dictamnus*). See *BALLOTA* and *MARRUBIUM*.

FALSE DRAGON'S HEAD (*Physostegia virginiana*. Nat. Ord. Labiatæ).—This must be distinguished from the true DRAGON'S HEAD—a name applied to the members of the genus *Dracocephalum* (see *DRAGON'S HEAD*)—which it resembles in some respects, as well as belonging to the same natural order, although botanically quite distinct. It is a useful hardy border plant, thriving in light, sandy soil, rich in rotted vegetable matter, but free from acid peat. It may be treated as a half-hardy annual by being raised in heat and planted out, when it will bloom rather late in the

same year. Root division in March, at which time it may be most successfully planted, or cuttings inserted in a frame in the summer are better means of increasing the stock. The plant itself bears attractive red flowers from July to August, and its variety *speciosa* is a delightful pink, while *alba* is a good white. The height of both averages 1½–3½ ft.

NEW VARIETY.

Physostegia verbenoides.—This has long leathery leaves, and bears small cream-white flowers in large trusses.

FALSE HELLEBORE.—See *VERATRUM.*

FALSE INDIGO (*Amorpha fruticosa*). See *SHRUBS.*

FALSE LOOSESTRIFE.—See *LUDWIGIA.*

FALSE MALLOW.—See *MALVASTRUM.*

FALSE MILDEWS.—See *MILDEWS.*

FALSE SOLOMON'S SEAL (*Smilacina.* Nat. Ord. Liliaceæ).—This must be carefully distinguished from *SOLOMON'S SEAL,* on which we devote a separate article. Some of the less important species are now included under *Clintonia*—a genus we do not describe in the present work. The plant is somewhat less poisonous than Solomon's Seal, and may be used for cutting.

Culture.—This is quite an easy matter. All the species described below will thrive in ordinary light sandy garden soil to which some leaf-mould has been added, if a sunny or very lightly shaded site is provided, and can be used for semi-wild gardening. Propagation is best effected by division of the roots in the spring, while the best months for planting are February and March. There are one or two greenhouse species which are excluded as being of little importance.

What to Grow.—We recommend the following :—

Smilacina oleracea.—This bears white flowers slightly tinted with rose-pink. It blooms in May and June, while its height averages about 1 yd.

S. racemosa (FALSE SPIKENARD).—This is a useful sort bearing light lemon-yellow flowers in May and June. It grows 6–12 ins. high.

S. stellata (STAR-FLOWERED LILY OF THE VALLEY).—This is probably the prettiest species of all. It bears starry-white flowers from May to June, and grows 6–9 ins. high.

FALSE SPIKENARD (*Smilacina racemosa*).—See *FALSE SOLOMON'S SEAL.*

FALSE STARWORT.—See *BOLTONIA.*

FARFUGIUM.—Now included in the genus *SENECIO.*

FARKLE-BERRY (*Vaccinium arboreum*).—See *SHRUBS.*

FARMYARD MANURE.

Strictly speaking, farmyard manure should be a mixture of horse, cow, pig, sheep, and poultry manure. If it is this, then it is well worth the usual price asked for it (6s. per load); but should it largely consist of cow manure, it will be very heavy, but little going to the ton, and in this case 4s. per load is as much as should be paid for it, to include carting a mile.

The gardener who can get as many tons of the best farmyard manure as he wishes, is indeed one of the lucky men of this world. He will be able to grow all the fine crops that he wishes, with very little need for the aid of artificial fertilisers. Most of us, however, are not able to get enough of it, even though we place our orders a long time in advance of when we require the manure. So we have to supplement farmyard manure with artificials.

Well-made farmyard manure is an almost perfect humic material. But it is doubtful whether, out of any hundred cases chosen, the

gardener receives the manure in anything like a perfect condition. More often than not when it arrives it is almost "red hot," due to over-quick fermentation, and in this condition it loses much of its value. Our opinion is that not more than 1 per cent. of the farmers of to-day know how to make farmyard manure properly. If they did, the crops produced by applying it to farm and garden land would be appreciably greater.

It is not our task in this Dictionary to give advice to farmers on making manure, but what we can do is to tell gardeners how to tackle it when it arrives in this highly undesirable condition.

Undoubtedly the first thing to do is to cool it. The manure should be shot up in the compost and manure yard, and should at once be spread out to allow as large a surface to be exposed as possible. The next thing to do is to drench it with cold water, or far, far better, to drench it with salt water, using 3 lb. of salt to every 30 gallons of water. After half an hour or so, the manure should have cooled very considerably; if it has not, more salt water should be thrown on to it. After this period it should be made into a solid, rectangular stack, the top portion of which should slope down to either side at an angle of 45°. The manure as it is built up should be beaten or trodden as firm as it can possibly be made, and a hole left at the top in which a thermometer can be placed. Should the temperature run up, some of the drainings of the drenching you gave your manure should be shot into the hole. If the temperature continues to rise, and you cannot bear the heat when you thrust your hand into the hole, then the stack must be taken to pieces again, the manure being shaken out anew, and further salt water applied. The heap is then re-made very, very firmly; loose stacking is responsible for more waste of farmyard manure than almost anything else.

The uses of farmyard manure are very numerous. It can be used for making into hotbeds (see article on *Hotbeds*); it can also be stacked for a year, when it becomes a beautifully mild, rich material for adding to potting soils for strong-growing subjects. It can be mixed with equal parts of rotted vegetable refuse for the trenching of land (see article on *Soil Cultivation*) and for making into mushroom beds. For digging into the surface soil of borders, or for surface-rooting crops, or indeed for the making of pea, bean, and celery trenches, it should be in a half-rotted condition, which condition is produced by allowing it to be stacked for a month or a trifle longer before use. For further information about manures, their management and use, the reader should refer to the following articles: *Manures*, and *Manuring: Principles of*.—E. T. E.

FASCIATION.—See *Diseases of Plants*.

FAT HEN.—A weed. For Means of Control see *Weeds*. See also *Chenopodium*.

FATSIA.—For the best species see *Shrubs*.

FEATHER GRASS (*Stipa pennata*).—See *Ornamental Grasses* and *Stipa*.

FEATHER (or FEATHERED) HYACINTH (*Muscari comosum monstrosum*).—See *Grape Hyacinth*.

FEATHERS AS MANURE.—See "Waste Hair" in our notes on organic products under Nitrogenous Manures in *Manures*.

FECA.—Now included in the genus Trichomanes, for which see *Ferns and Fern Gardening*.

FEDIA.—Now included in the genus *Valerianella*, which see.

FEEDING PLANTS.

What is our object in feeding our plants? Very briefly we may say this important work is undertaken to secure a crop that is economically profitable, and every gardener recognises that all plants, whether fruits or vegetables, ornamental trees or shrubs, or foliage and flowering plants, are greatly benefited by the application of proper fertilisers or plant foods. No matter how perfect is the general cultivation, that crop will not give the best return if the soil is lacking in an essential element of plant food; and it should be the object of every gardener to see that the soil is sufficiently provided with at least three substances, namely, nitrogen, phosphates, and potash. A fourth substance, lime, is also necessary, but it is not applied directly as a plant food, but more because of its physical effect upon the soil.

What Crops Need.—Each element of plant food has a particular work to perform, and is applied for a particular purpose. For instance:—

Beans require phosphates and potash for seed production;

Cabbages need nitrogen for leaf production;

Celery needs nitrogen and phosphates for stem and leaf production;

Potatoes need nitrogen and potash for leaf and tuber production;

Turnips require potash and phosphates for root formation, and for the manufacture of sugar and starch; and so on.

When to Apply.—In applying plant foods it is most important to give the dressings at the right time. It is useless to apply a plant food at a time when the crop can obtain no material benefit from the application. For example, it would be waste of money and labour to apply basic slag to a quick-growing crop in the growing season, because the phosphates in basic slag are not readily available, and the crop would be harvested before the basic slag had been able to give to the plant any soluble phosphates. It will be easily understood that those plant foods which are not readily available must be applied when the ground is not occupied with the crops; the plant can then obtain full benefit from the dressing. Quick-acting manures, such as nitrate of soda, sulphate of ammonia, etc., must be applied when the crop is growing, for, if applied in winter or early spring, the soluble food would be washed away by the rains before the plants could derive any benefit from their use.

The slow-acting phosphatic plant foods, such as basic slag and bone-meal, should be applied in the autumn or early winter, during trenching or digging operations. This enables the phosphates to be rendered soluble by the time the plant is ready to absorb this element. Superphosphate, another plant food supplying phosphate, is more active than basic slag, and is applied in spring when the ground is forked over after digging or trenching and prepared for seed sowing and planting.

Potassic manures, such as muriate of potash and kainit, are fairly active, and should be applied in late spring. Sulphate of potash is readily soluble, and may be applied to a growing crop with benefit.

How to Apply.—Plant foods may be applied in two forms, namely, solid and liquid. The insoluble plant foods are applied in the solid form, and the soluble plant foods may be either applied in the solid or liquid state. When applied in the liquid form they are even more quick-acting, as they have not to be dissolved by the soil water before they act. Applying manures in the liquid state is termed *Liquid*

Manuring, and it is a convenient method of giving soluble manures in the case of small plots or greenhouses when the plants are growing. Nitrate of soda, sulphate of potash, sulphate of ammonia, and superphosphate may be readily applied by making weak solutions of these substances, and a dilute solution of farmyard manure will also be found an excellent stimulant for growing crops. In applying liquid manures the solutions should be very weak, and the applications should be given about once a week. It is most important that the liquid should not come in contact with the stem or foliage, and if the soil is dry it should be well watered before applying the liquid manures, otherwise they will sink below the reach of the plants and much will be lost, as well as burning the roots maybe.

Food for all Crops.—The following dressings will be found best suited for the varous crops, the quantities in each case being for *one square rod* (30¼ sq. yds.) unless otherwise stated :—

Beans.—See under Peas, below.

Cabbage Tribe.—Apply 3 lb. of superphosphate of lime[1] broadcast before planting, and when established, sprinkle a teaspoonful of sulphate of ammonia at the base of each plant.

Celery.—Apply 3 lb. of superphosphate of lime in the trenches before planting, and as a top-dressing, 1 lb. of sulphate of ammonia when the plants are established.

Fruit Trees.—Apply 3 lb. of bonemeal in the winter. In the spring apply 1 lb. of sulphate of ammonia and 1 lb. of superphosphate of lime.

Lettuce.—See under Saladings, below.

Peas and Beans.—Apply 3 lb. of superphosphate of lime, scattering it along each thirty-yard run or row before sowing, and if the plants appear to need a stimulant, apply ½ lb. of sulphate of ammonia to the same area, when they are about 3 ins. high.

Potatoes.—Apply 4 lb. of superphosphate of lime in the rows of drills when planting, and 1½ lb. of sulphate of ammonia just before earthing up. Dress the ground in the winter with 4 lb. of kainit, or 8 lb. of wood ashes.

Root Crops.—Apply 4 lb. of superphosphate of lime, a fortnight before sowing, and as a top-dressing use 1 lb. of sulphate of ammonia or 1¼ lb. of nitrate of soda.

Saladings.—Sprinkle 2 oz. of superphosphate of lime per sq. yd. on the ground before planting out, and ½ oz. of sulphate of ammonia when the plants are established.

Tomatoes (*Indoor*).—To each bushel of soil add 8 oz. of the following mixture :—

Sulphate of ammonia, 1 oz.
Sulphate of potash, 3 oz.
Superphosphate of lime, 6 oz.

After the first truss of fruit is formed, the plants will benefit by being watered every fortnight with 4 oz. of the above mixture per 5 gals. of water. The first ingredient may be omitted if the soil is very rich.

Tomatoes (*Outdoor*).—Apply 3 oz. of the above mixture per sq. yd. when planting out.

Vegetable Marrows.—Animal manure in liquid form may be applied from the time the first six fruits have set. Fertiliser may be used, and 1 oz. of superphosphate of lime per 2 gals. of water once a week is useful.—J. K. R.

[1] Where superphosphate of lime is recommended, basic slag is preferable if the soil is heavy. Apply 4–5 lb. per sq. rod, as early in the winter as possible.—Editor.

FEEDING VEGETABLES.—See *FEEDING PLANTS*, and under GENERAL MANAGEMENT in *VEGETABLES: GENERAL CONSIDERATIONS*.

FENUGREEK.—See *TRIGONELLA*.

FENZLIA.—Now included in the genus *GILIA*, which see.

FERMENTS.—See *GERMINATION OF SEEDS*.

FERN HOUSES. — See *FERNS AND FERN GARDENING*.

FERN-LEAF EELWORM.—See under EELWORMS in *INSECT PESTS*.

FERN-LEAVED OAK (*Quercus pedunculata filicifolia*).—See *TREES*.

FERN (MALE). — See *MEDICINAL HERBS*.

FERNS DISLIKING LIME.—See *LIME HATERS*.

FERNS AND FERN GARDENING: GREENHOUSE AND HALF-HARDY FERNS.—Ferns will always be more or less extensively cultivated for their delicate beauty, finely cut fronds, the restfulness of their greenery, their utility for home decorations in a variety of ways, for mixing with cut flowers, the interest attaching to them in many ways, and lastly as a hobby, when the cultivator may develop into a specialist and cultivate them to the exclusion of most or every other kind of plant.

Fern Houses.—Some attention must be given to the situation of the fern house by those who would grow these subjects successfully. They dislike too much or too intense sunshine, and though the house may be shaded it will save labour in this respect if the structure faces the east or north. The builder or owner may fix upon such a site for the sake of convenience, and the latter attempt the cultivation of flowering plants in the house with partial or complete failure, but find that Ferns grow admirably in it. The house may even face the south if it is shaded from the east and west by wings of the dwelling, because the short period of exposure to direct sunlight has no injurious effect. Greenhouse Ferns may be grown in an unheated house or even in a cold frame during the summer, but it should be furnished with a heating apparatus in order that the fire may be lighted during frosty nights or frosty periods, in the winter, so that the temperature may be kept from falling much below 40–45° F., during the night or early morning. In any case frost should be excluded.

No attempt should be made by amateurs to grow stove Ferns, which require a night temperature of 55–60° F., under the above conditions, otherwise the results will generally be unsatisfactory. Half-hardy Ferns may be grown to perfection in such a house, if attention is given to their special requirements. All Ferns require a certain amount of atmospheric moisture, more especially in summer when making their growth. Half-hardy sorts, such as *Adiantum Capillus-Veneris*, the Killarney, *Todea superba*, and other filmy Ferns, will be happy if frost is more or less excluded and they are covered with a bell-glass or special case to preserve moisture about them. The Walking Fern (*Scolopendrium rhizophyllum*), as well as *Aspidium falcatum* and its varieties, will live outside in mild and maritime districts, but should be sheltered by evergreen boughs during the colder and more windy periods of the winter.

Potting Ferns. — Indoor sorts

should be rested by keeping them cooler and drier overhead and at the roots during the autumn and winter, from October onwards. When they begin making fresh growth about March that is the time to repot them, before the young fronds are long enough to get broken in the operation. The old ball of soil may be considerably reduced to enable the plants to be put in the same size of pot, or a slightly larger one according to the quantity of roots. Young plants, making rapid growth, may be repotted into larger sizes several times a year, without reducing the ball. Press the soil fairly firmly about the roots of old plants, but considerably less about quickly growing young ones.

Most Ferns may be grown in a compost consisting of two-thirds fibrous loam, the other third being made up of good leaf-mould, well-decayed manure, and coarse sand. This is specially suitable for Maidenhair Ferns. Most other kinds will also grow well when one-third of peat is used instead of the leaf-mould and manure. Leaf-mould should be sifted to take out the rubbish, and the manure should be dry enough to be rubbed through a half-inch sieve. The loam and peat should be broken up and lumpy, but should never be sifted.

Propagating Ferns.—Ferns may be increased at the time of potting by dividing those that make more than one crown, such as Davallias, Maidenhairs, Pteris, and others. Hartstongues, Nephrodiums, and others occasionally produce small offsets at the side of the crowns, and these may be removed and potted. Some of the Aspleniums and other genera produce small plants on the fronds: these may be dibbled into pans of compost, or whole fronds may be pegged down till the young plants are rooted. Spores are the most rapid means of propagation for a large proportion of the Ferns. Keep a close eye upon the fronds, and when the spore cases begin to turn brown remove a frond or portions of it, and wrap them up in white paper, putting them in a closed box for a few days, when an abundance of spores for sowing will be available. Fill some pots with good loam, to within an inch of the top, using no drainage, and surface this with some finely broken and dusty crocks or bricks. Give a thorough watering, and when this has soaked away sow the spores as thinly as possible. Stand each pot in a saucer of water, cover it with a piece of glass, and place it in a case or under a bell-glass where light is available, but where there is no direct sunshine. When the pots get covered with small green scales (*prothallia*), transplant some of the small tufts with a pointed peg into other pots filled with compost and surfaced with sandy soil. Saucers of water beneath the pots should be used to supply moisture.

Ventilating Fern Houses.—Free ventilation must be given on all favourable occasions during growth to keep down the temperature of the house, and enable the plants to make sturdy and firm growth. Usually it will be sufficient to open the top ventilators except during the hottest periods, but even then the side ventilators should not be used to excess or the air of the house may be rendered too arid for the welfare of the plants.

Watering Ferns.—Newly potted Ferns should be watered through a fine rose to settle the soil, and no more water given till actually required. As the plants begin to grow freely, they will require to be watered more and more frequently, till when in full growth, during the heat of summer, they may require

watering every day, though it should not be given unless they are actually dry. There should be no stagnant water about the roots, so that provision should be made for clear drainage at the time of potting. It will not be necessary to syringe the plants overhead, if the air is kept moist by damping down all paths and open spaces once or oftener a day. Hard or chalky water is liable to spot or disfigure the fronds, and rain water is in every way preferable. Less water will be required in winter, but the soil should never be allowed to get dust dry, whether the plants are evergreen or deciduous.

Hardy Ferns. — Shade and moisture are two of the principal requisites in the successful culture of hardy Ferns outdoors. The nature of the soil does not very much matter, provided it can be kept sufficiently moist during the summer months. Aids to this effect are secured by selecting the situation, by using soil of a moisture-retaining nature, by employing a liberal quantity of peat or leaf-mould, or both, before planting, and by giving annual top-dressings of either in spring, after the old fronds have been cut away and the Ferns are about to commence fresh growth. The fading fronds should not be cut away in the autumn, because they afford a natural protection to the crowns. The effect of a hardy fernery is greatly heightened if it is built up in the form of a rockery, with more or less bold elevations and rocky, projecting angles, according to size, as in the case of rockeries for alpine flowering plants. A stream, either natural or artificial, furnishes variety, and its banks may be clothed with the stronger-growing sorts, such as Lady Ferns, Ostrich Feather, The Royal Fern, and others that delight in ample supplies of water. Care should be taken in planting the smaller Ferns, that they do not get overhung and smothered by their taller neighbours. Shrubs of fair height, or trees, may be planted on purpose to furnish shade, but care should be taken to prevent the roots from encroaching on the Fern ground.

Hardy Ferns, mostly British, may be grown entirely in the greenhouse in pots or planted out on rockeries. The house may be unheated or merely heated to exclude frost. By this latter means the evergreen species remain bright and fresh throughout the winter. The soil must be kept moist in the winter whether the plants are deciduous or evergreen, and copious supplies of water will be needed in the summer. British Ferns are as handsome as exotics and more extensively diversified in form. They are propagated in the same ways as the greenhouse and half-hardy sorts above dealt with.

What to Grow.—In the selections given below, *G.F.* signifies that it is a greenhouse Fern; *H.F.* denotes that it is hardy; and *H.H.F.* means that it is half-hardy. Only the very best species and varieties are referred to on account of keeping the list within reasonable limits.

Adiantum Capillus-Veneris (*G.F.* or *H.H.F.*).—The Common Maidenhair or Maidenhair Fern, and its varieties *crispulum*, *magnificum*, and *undulatum*. Height, 1 ft.

A. cuneatum (*G.F.*), and its varieties *gracillimum*, *grandiceps*, *grandis*, and *Lawsoni*. Height, 1 ft.

A. excisum (*G.F.*), and its variety *multifidum*. Height, 6–12 ins.

A. formosum (*G.F.*). Height, 1–2 ft.

A. hispidul (*G.F.*), and its variety *tenellum*. Height, 1 ft.

A. Moorei (*G.F.*). Height, 1½ ft.

A. pedatum (*H.F.*). Height, 1–2 ft.

A. tenerum (*G.F.*), and its variety *Victoriæ*. Height, 6–12 ins.

A. Wagneri (*G.F.*). Height, 1 ft.

Anemia Phyllitidis (*G.F.*). Height, 1 ft.

Aspidium acrostichoides (*H.F.*). Height, 1–2 ft.

A. aculeatum (*H.F.*).—The PRICKLY SHIELD FERN, and its varieties *cruciatum, pulcherrimum,* and *pulcherrimum gracillimum Drueryi*. Height, 2–3 ft.

A. angulare (*H.F.*).—The SOFT PRICKLY SHIELD FERN, and its varieties *cristatum, cruciatum, divisilobum cristatum, divisilobum densum, plumosum,* and *proliferum densum*. Height, 2–3 ft.

A. aristatum (*G.F.*), and its variety *variegatum*. Height, 1 ft.

A. capense (*G.F.*). Height, 2–4 ft.

A. falcatum (*G.F.* or *H.H.F.*), and its varieties *caryotideum, Fortunei,* and *Rochfordii*. Height, 12–18 ins.

A. Lonchitis (*H.F.*).—The HOLLY FERN. Height, 6–12 ins.

A. munitum (*H.F.*). Height, 1–2 ft.

Asplenium Adiantum-nigrum (*H.F.*).—The BLACK MAIDENHAIR SPLEENWORT. Height, 1 ft.

A. bulbiferum (*G.F.*), and its varieties *fabianum, laxum,* and *minus*. Height, 2–3 ft.

A. flaccidum (*G.F.*), with drooping fronds. Length, 1–2 ft.

A. fontanum (*H.F.*).—The SMOOTH ROCK SPLEENWORT. Height, 3–6 ins.

A. marinum (*G.F.* or *H.H.F.*).—The SEA SPLEENWORT, and its varieties *imbricatum* and *ramosum*. Height, 6–12 ins.

A. obtusatum lucidum (*G.F.*). Height, 2–2½ ft.

A. septentrionale (*H.F.*).—The FORKED SPLEENWORT. Height, 3 ins.

A. Trichomanes (*H.F.*). — The BLACK-STEMMED SPLEENWORT, and its varieties *cristatum, Moulei,* and *multifidum*. Height, 3–12 ins.

A. viride (*H.F.*).—The GREEN SPLEENWORT. Height, 3–4 ins.

Athyrium Filix-fœmina (*H.F.*).—The LADY FERN, and its varieties *cruciatum, Fieldiæ cristatum, Frizelliæ, plumosum, plumosum superbum Drueryi, pulcherrimum,* and *Victoriæ*. Height, 2–4 ft.

Blechnum brasiliense (*G.F.* or *H.H.F.*).—The TREE BLECHNUM, and its variety *corcovadense*. Height, 2–3 ft.

B. occidentale (*G.F.*). Height, 12–18 ins.

Camptosorus. See *Scolopendrium rhizophyllum*.

Cryptogramme crispa (*H.F.*).—The MOUNTAIN PARSLEY. Height, 12 ins.

Cyrtomium. See *Aspidium falcatum*.

Cystopteris alpina (*H.F.*).—The ALPINE BLADDER FERN. Height, 6–12 ins.

C. bulbifera (*H.F.*). Height, 12–18 ins.

C. fragilis (*H.F.*).—The BRITTLE BLADDER FERN, and its varieties *cristata, dickieana,* and *sempervirens*. Height, 6–12 ins.

C. montana (*H.F.*).—The MOUNTAIN BLADDER FERN. Height, 6–9 ins.

Davallia bullata (*G.F.*), and its varieties *Mariesii* and *Mariesii cristata*. Height, 6–12 ins.

D. canariensis (*G.F.*).—The HARE'S FOOT FERN. Height, 12–15 ins.

D. elegans (*G.F.*), and its varieties *elata* and *polydactyla*. Height, 1 ft.

D. hirta (*G.F.*), and its variety *cristata*. Height, 2–4 ft.

D. tenuifolia (*G.F.*), and its varieties *Burkei, stricta,* and *Veitchii*. Height, 12–18 ins.

Doodia aspera (*G.F.*), and its varieties *gigantea* and *multifida*. Height, 6–12 ins.

D. caudata (*G.F.*). Height, 6 ins.

Doryopteris. See *Pteris palmata.*

Gymnogramme calomelanos (*G.F.*). —The SILVER FERN, and its varieties *chrysophylla* and *Martensii*, both known as the GOLD FERN. Height, 1 ft.

G. pulchella (*G.F.*).—The SILVER FERN. Height, 1 ft.

Hymenophyllum tunbridgense [1] (*G.F.* or *H.H.F.*).—The TUNBRIDGE FILMY FERN, and its variety *Wilsoni*. Height, 3 ins.

Lastrea. See *Nephrodium.*

Lomaria alpina (*H.F.*). — The ALPINE HARD FERN. Height, 6–9 ins.

L. ciliata (*G.F.*), and its varieties *grandis* and *major*. Height, 1 ft.

L. gibba (*G.F.*), and its variety *tincta*. Height, 1–2 ft.

L. Spicant (*H.F.*).—The HARD FERN, and its varieties *concinnum, cristatum, imbricata, plumosum*, and *ramo-cristatum*. Height, 1 ft.

Lygodium japonicum (*G.F.*).—The CLIMBING FERN, or SNAKE'S TONGUE FERN. Height, 5–6 ft.

Nephrodium æmulum (*H.F.*).—The HAY-SCENTED BUCKLER FERN. Height, 1–2 ft.

N. decompositum (*G.F.*), and its varieties *glabellum* and *Shepherdi*. Height, 1 ft.

N. erythrosorum (*G.F.* or *H.H.F.*). Height, 1–2 ft.

N. Filix-mas (*H.F.*)—The MALE FERN, and its varieties *cristatum, polydactylum, pseudo-mas, pseudo-mas cristatum* (the KING OF MALE FERNS), and *pseudo-mas cruciatum*. Height, 2–4 ft.

N. goldieanum (*H.F.*). Height, 2–3 ft.

N. molle (*G.F.*), and its variety *corymbiferum*. Height, 18 ins.

N. montanum (*H.F.*). — The MOUNTAIN BUCKLER FERN, and its variety *cristatum*. Height, 1–2 ft.

N. patens (*G.F.*). Height, 1–2 ft.

N. remotum (*H.F.*).—The REMOTE BUCKLER FERN. Height, 12–15 ins.

N. rigidum (*H.F.*).—The RIGID BUCKLER FERN. Height, 12–15 ins.

N. spinulosum (*H.F.*). — The PRICKLY-TOOTHED BUCKLER FERN, and its variety *dilatatum* (the BROAD BUCKLER FERN). Height, 1–3 ft.

N. Thelypteris (*H.F.*). — The MARSH BUCKLER FERN, or MARSH SHIELD FERN. Height, 1–2 ft.

Nephrolepis exaltata (*G.F.*), and its varieties *elegantissima, Marshalli compacta*, and *todeoides*. Height, 1–4 ft.

Onoclea germanica (*H.F.*).—The OSTRICH FERN. Height, 2–3 ft.

O. sensibilis (*H.F.*).—The SENSITIVE FERN. Height, 1 ft.

Onychium japonicum (*G.F.*). Height, 1 ft.

Osmunda cinnamomea (*H.F.*). Height, 2 ft.

O. Claytoniana (*H.F.*). Height, 2 ft.

O. palustris (*G.F.* or *H.H.F.*), and its variety *congesta*. Height, 2–3 ft.

O. regalis (*H.F.*). — The ROYAL FERN, and its variety *cristata*. Height, 2–6 ft.

Pellæa cordata (*G.F.*). Height, 1 ft.

P. falcata (*G.F.*). Height, 1 ft.

P. rotundifolia (*G.F.*). Height, 1 ft.

Platycerium alcicorne (*G.F.*).—The ELK'S HORN FERN, and its varieties *cordreyi* and *Hillii*. Height, 12–15 ins.

Polypodium appendiculatum(*G.F.*). Height, 6 ins.

P. aureum (*G.F.*), and its varieties *cristatum* and *glaucum*. Height, 1–2 ft.

P. Dryopteris (*H.F.*).—The OAK FERN, and its variety *Robertianum* (the LIMESTONE POLYPODY). Height, 1 ft.

P. Lingua (*G.F.*), and its variety *corymbiferum*. Height, 1 ft.

[1] Grow these under a bell-glass.

P. Phegopteris (*H.F.*). — The BEECH FERN. Height, 12–18 ins.

P. vulgare (*H.F.*).—The COMMON POLYPODY, and its varieties *cambricum* (the WELSH POLYPODY); *cornubiense* (CORNISH POLYPODY); *semilacerum* (IRISH POLYPODY); and *trichomanoides*. Height, 9–12 ins.

Polystichum. See *Aspidium*.

Pteris cretica (*G.F.*), and its varieties *albolineata, crispata, major, nobilis,* and *Wimsetti*. Height, 1–2 ft.

P. palmata (*G.F.*). Height, 9–12 ins.

P. serrulata (*G.F.*).—The RIBBON FERN, and its varieties *chiswickense, cristata, gloriosa,* and *gracilis*. Height, 1–2 ft.

P. tremula (*G.F.*).—The AUSTRALIAN BRACKEN, and its varieties *flaccida* and *Smithiana*. Height, 1–2 ft.

P. umbrosa (*G.F.*). Height, 1 ft.

Scolopendrium rhizophyllum (*G.F.* or *H.H.F.*).—The WALKING FERN. Height, 4 ins.

S. vulgare (*H.F.*).—The HARTS-TONGUE FERN, and its varieties *corymbiferum, crispum, crispum grande, crispum maximum, Kelwayi, ramo-cristatum,* and *spirale*. Height, 1 ft.

Todea barbara (*G.F.*). Height, 1½ ft.

T. superba[1] (*G.F.* or *H.H.F.*). Height, 1–2 ft.

Trichomanes radicans[1] (*G.F.* or *H.H.F.*).—The KILLARNEY FERN. Height, 9–18 ins.

Woodsia alpina (*G.F.* or *H.H.F.*). —The ALPINE WOODSIA. Height, 2–3 ins.

W. ilvensis (*G.F.* or *H.H.F.*).—The OBLONG WOODSIA. Height, 3–4 ins.

Woodwardia radicans (*G.F.*).—Height, 2–3 ft.—J. F.

[1] Suitable only for growing in a Fern case.

NEW VARIETIES.

The following are among the best and most noteworthy :—

Adiantum gloriosum Lemkesii.—A greenhouse fern, the young fronds of which are tinted light red, but change to pale green.

A. grossum.—A handsome fern from tropical America, with large, leathery pinnules.

Polypodium Dryopteris plumosum Christopherson.—A fine fern with much-divided highly-cut deep green leaves, which are often 2–3 ins. across.

FERNS FOR NORTH BORDERS.—See HARDY FERNS in *NORTH BORDERS*.

FERROCYANIDE OF POTASH.—See POTASSIUM FERROCYANIDE in *POTASH AND POTASSIUM COMPOUNDS*.

FERROUS SULPHATE.—See *IRON AND IRON COMPOUNDS*.

FERTILISATION OF PEACHES.—See *PEACHES*.

FERTILISER TOP-DRESSINGS.—See *TOP-DRESSING*.

FERTILISERS.—See *ARTIFICIAL FERTILISERS* and *FEEDING PLANTS*.

FERTILISERS, MANURES, AND SOILS : WEIGHTS OF BUSHELS OF.—See *WEIGHTS AND MEASURES*.

FERTILISERS : QUICK-ACTING.

The following list contains the more important manures or fertilisers which act quickly, details of the use of which will be found usually in the article on the metal in question, thus *Chloride of Soda* will be found under SODIUM CHLORIDE in our article on *SODA AND SODIUM COMPOUNDS*.

Chile Saltpetre (or *Nitrate of Soda*).
Chloride of Ammonia.
Chloride of Soda.
Dissolved Bones.
Dissolved Guano.
Dried Blood.
Epsom Salts (or *Sulphate of Magnesia*).
Guano.
Glauber's Salts (or *Sulphate of Soda*).
Green Vitriol (or *Sulphate of Iron*).

Nitrate of Ammonia.
Nitrate of Lime.
Nitrate of Potash.
Nitrate of Soda.
Phosphate of Ammonia.
Phosphate of Potash.
Phosphate of Soda.
Pigeon Dung.
Poultry Manure.
Sal-ammoniac (or *Chloride of Ammonia*).
Salt (or *Chloride of Soda*).
Saltpetre (or *Nitrate of Potash*).
Sulphate of Ammonia.
Sulphate of Iron.
Sulphate of Potash.
Sulphate of Soda.
Superphosphate of Lime.

FERTILISERS: SLOW-ACTING.

The following list contains the most important fertilisers or manures which are somewhat slow in action. Details will be found in other articles, usually on the metal in question, as to how to use them, *i.e. Chloride of Potash* will be found under POTASSIUM CHLORIDE in our article on *POTASH AND POTASSIUM COMPOUNDS*.

Basic Slag.
Basic Superphosphate.
Bone Dust.
Bonemeal.
Carbide Refuse.[1]
Carbonate of Ammonia.
Carbonate of Lime.
Carbonate of Magnesia.[1]
Carbonate of Potash.
Carbonate of Soda.[1]
Chalk (or *Carbonate of Lime*).
Chloride of Magnesia.
Chloride of Potash.
Cyanamide.
Ground Bones.
Gypsum (or *Sulphate of Lime*).
Hoof Parings.
Horn Dust.
Ivory Dust.
Kainit.
Muriate of Potash (or *Chloride of Potash*).
Nitre Cake.
Nitrolim (or *Cyanamide*).
Phosphate of Lime.
Reverted Superphosphate.
Slaked Lime.
Sulphate of Lime.
Sulphate of Magnesia.
Wood Ashes.

[1] These are not very slow, but owing to their caustic or concentrated properties they should be used with caution.—EDITOR.

FERULA (GIANT FENNEL. Nat. Ord. Umbelliferæ).—This is a genus of coarse-growing hardy herbaceous perennials of very easy culture and suitable for the wild garden. It must not be confused with the genus *FOENICULUM* (which see), containing the COMMON FENNEL described under FENNEL in our article on *MEDICINAL HERBS*. The chief species, which bear yellow flowers from June to August, and grow 1–4 ft. in height, are *F. Assafoetida* (or *F. foetida* of some authorities), the source of that noxious drug Assafetida; *F. galbaniflua*, the GALBANUM PLANT; *F. glauca*, useful in very large borders; *F. Narthex* (Syn. *F. Polaki*), objectionably known as DEVIL'S DUNG; and *F. Sumbul*, the comparatively well-known plant SUMBUL. For the very many other species larger works must be consulted.

FERULAGO.—Now included in the genus *FERULA*, which see.

FESCUE GRASS.—See *FESTUCA*.

FESTUCA (FESCUE GRASS. Nat. Ord. Gramineæ).—This is a large genus of grasses, including ornamental, pasture, and lawn species. *F. varia* is probably the best of the first, and grows 3–4 ins. high. The HARD FESCUE (*F. duriuscula*) and SHEEP'S FESCUE (*F. ovina*) are among the best of the second, while *F. ovina* and *F. rubra* are good on lawns (see article on *LAWNS AND THEIR MANAGEMENT*). Other notable species include *F. elatior*, the DOVER GRASS, and its variety *pratensis*, the well-known MEADOW FESCUE; *F. montana altissima*, known as ARAB'S DISS; and *F. Myuros*, the well-known MOUSE-TAIL GRASS.

FEVERFEW.—See *MEDICINAL HERBS*.

FICARIA.—Now included in the genus *RANUNCULUS*.

FIDDLE DOCK (*Rumex pulcher*).—See *RUMEX*.

FIELD MADDER (*Sherardia arvensis*. Nat. Ord. Rubiaceæ).—This is a weedy plant of no commercial or horticultural importance. MADDER (True) is referred to under *RUBIA*, which see.

FIELD MARIGOLD (*Calendula arvensis*).—See *MARIGOLD*.

FIELD PEA (*Pisum arvense*).—See *PISUM*.

FIELD POPPY (*Papaver Rhoeas*).—See *POPPIES: ANNUAL SPECIES*.

FIELD SLUG.—See under SLUGS AND SNAILS in *INSECT PESTS*.

FIG (*Ficus Carica*. Nat. Ord. Urticaceæ).—The fig will accommodate itself to almost any kind of structure and mode of training. A good lean-to house answers best for early forcing, while span-roofed pits are best adapted for pot-culture. Figs continue to produce fruits for a long time after the first flush of fruits are gathered. They are gross feeders and strong growers, and therefore require a circumscribed space for their roots. They may be trained on wires as provided for vines and peaches. Prepare the border with concrete and drainage as recommended for peaches, and allow a square foot of border to every square yard of trellis.

Compost.—A medium loam tending to be sandy is the most suitable, but if a heavier loam is used, this must be corrected by the addition of lime rubble, broken bricks, burnt earth, and road scrapings. Always place a turf, grass side downwards, over the drainage, chop up the turf roughly, add the above correctives, and mix thoroughly.

Avoid manures, as young fig trees generally grow too fast the first few years. Make up the border, using fresh turf for a retaining wall. Plant in early spring, carefully disentangling the roots, and spread them out carefully. Make thoroughly firm, and cover the roots with about 3 ins. of compost.

Forcing.—Where early forced figs are required, pot-trees are almost indispensable, as they are easily managed and most productive. Moderate growers and free fruiting varieties are the most suitable, such as *Brown Turkey, St John, Violette Sepor*, and *White Marseilles*. If the trees can be plunged into a moderate bottom heat of say 70–75° F., so much the better. Commence with a temperature of 50° F. at night, with a rise of 10° during bright days, increasing the temperature gradually up to 63° F. at night, with the usual rise during the day. Although the green fruits are liable to drop, they must be finally thinned to about three on each shoot. Pinch out the points of the shoots, when fertilisation is complete, to five or six leaves, increasing the temperature and moisture accordingly. Ventilation must be regulated according to the outside atmosphere. Liberally feed the plants with diluted liquid manure when carrying heavy crops, and never allow the trees to suffer for want of water. Give more air, with a slightly drier atmosphere, and discontinue syringing when the fruits begin to ripen. Permanent planted trees should be treated in a similar manner. Many grow their trees on the extension system of training, and never stop the shoots, with equally satisfactory results when grown in a confined border. Liberal feeding, thin training, and plenty of moisture are their

chief requirements. After the crop is gathered, cleanse the trees of any insects, taking care to do any stopping or pinching of the shoots in time for another growth to mature before the leaves fall.

Varieties.—*Bourjasotte Grise.*—Medium size, black, rich, and excellent.

Brown Turkey.—See next article.

Negro Largo.—Black, hardy, and prolific, one of the best.

Osborn Prolific.—White flesh, medium size, and good.

Pingo de Mel.—Medium size, yellow flesh, rich, and good.

White Marseilles. — See next article.—F. J.

FIG : Outdoor Culture.

In the southern and western counties the fig flourishes as a standard or big bush. There are at Worthing fig trees of timber size.

It is a great mistake to plant figs in a rich soil; they delight in plenty of porous stones, brick bats, etc., in the soil, and then make stout, short-jointed wood, which fruits freely. The figlets, carried through the winter, develop in spring, and an autumn crop is also to be looked for. On walls the main stems should be kept widely apart, so that the breast wood from these can extend outwards, where it generally fruits freely. If very dry in July and August, a liberal watering will swell the fruits. From time to time take out here and there some old wood boughs and lay in younger shoots. In winter regulate the boughs, and in summer cut out any sappy long shoots to let in sun and air.

Varieties.—There are only a few suitable for outside culture, the best four of which are given below :—

Angelique.—Skin green, flesh jelly like. Very delicate and sweet.

Brown Turkey.—Blackish-green. A very free bearer. Fruit delicious in flavour; the most reliable.

Brunswick.—Very large, greenish-purple. A strong, vigorous grower, though it crops sparsely; fine flavour.

White Marseilles.—Like *Angelique* this fruits freely and ripens early.—G. B.

FIG MARIGOLD.—A popular name applied to the genus *MESEMBRYANTHEMUM*, which see.

FIGWORT (*Scrophularia.* Nat. Ord. Scrophulariaceæ). — The genus Scrophularia is a small and not very important one, containing mostly hardy herbaceous perennial plants of easy culture. These thrive in ordinary light loam in a sunny or lightly shaded site, and may be propagated by seeds sown in the usual way in the summer, or by division of the roots in the autumn or spring, which latter period is the best time for planting.

What to Grow.—Only a few species can be described here, and for others reference to larger works must be made :—

Scrophularia aquatica variegata (WATER BETONY).—This may be used in the wild or water garden on account of the leafage. The flowers (produced in July) are an unattractive brown purple, and the plants grow about 1 yd. in height.

S. chrysantha.—This bears golden-yellow flowers from April to June, and grows about 2 ft. high.

S. nodosa (GREAT PILEWORT).—This bears scarlet flowers in July, and grows about 2 ft. high.

S. vernalis.—This is a yellow May flowering biennial species growing about 2 ft. high.

FIGWORT.—A name applied also to the genus *LINDENBERGIA*, which see.

FILBERT (*Corylus Avellana*).—See under COBNUT in *NUT CULTURE*.

FILIPENDULA.—Now included in the genus *SPIRAEA*, which see.

FINGER AND TOE DISEASE.—See under CLUBROOT in *DISEASES OF PLANTS*.

FIR.—A name applied to the genus ABIES. See *TREES*.

FIR CONES.

Gardeners often wonder what to do with the fir cones which are dropped from trees annually, and sometimes they mix them with heaps of leaves in the hope they will rot down. The best way is to save them up and use them for fuel in the house throughout the winter. During the burning a delightful pine odour is given off, and as we sniff it in our easy chairs our thoughts soon fly back to the glories of the summer garden.

FIRE BUSH.—The genus EMBOTHRIUM and *E. coccineum*. See *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

FIRE FUNGUS.—See under DISEASES in *TULIPS*.

FIRE PINK (*Silene virginica*).— See *SILENE*.

FIRE THORN (*Crataegus Pyracantha*). See *CLIMBING AND TRAILING PLANTS* and *TREES*.

FISH AS MANURE.

Rotten fish is about one of the foulest smelling materials there is; but it is also one of the best manures where a phosphatic and humic manure is required. Thus full advantage should be taken of supplies by gardeners on the coast, and the production of the land will be enormously increased. We give below a few brief particulars of the various forms of fish available and the modes of using them as manures :—

Bad Fish.—In large fishing towns after a very big catch it often happens that it is impossible in warm weather to dispose of all the supplies before some of the fish gets what is popularly known as "touched." In bald language the heat quickly makes it go bad unless it is stored on ice. A supply of this bad fish is often available in large towns, for if a barrel is opened and the fish is not all that it ought to be, that barrel is condemned as unfit for human food, which means that it is as a rule sent off to a destructor to be burnt. Gardeners should secure a supply of this, preferably in the early autumn or winter, and either dig it in in a raw state, or mix it with soil in the manner described in a succeeding paragraph. It is very useful for most vegetables, fruit trees, and the more gross feeding hardy perennials.

Fish Bones.—A large supply of these is usually available at most fishing towns, and some can usually be obtained very cheaply at the fish markets in the larger inland towns where much fish is consumed. The bones make a very rich phosphatic manure if dissolved in sulphuric acid in the same way as ordinary bones, and this material can be used for most crops at the rate of 1 oz. per sq. yd.

Fish Guano.—This material is dealt with in our article on *GUANO*, to which reference should be made for a description of its uses and mode of application.

Fish Heads and Tails.—These are often available in fair quantities at large fish markets both on the coast and inland. To use them they should be well chopped up with a sharp spade and preferably mixed with half their own bulk of hot fermenting stable dung. The heap should then be covered with soil and allowed to mellow down for a couple of months, after which the material can be dug in at the rate of a good forkful per square yard for vegetables, and rather less for flowers. Another way of preparing them is to mix them with about a quarter of their own bulk of wood ashes,

making the material into a heap with a hole at the top. On to this, human urine is poured until the mass is thoroughly saturated; then the heap is covered with several inches of soil and a slate put over the hole. In about a week's time the process of soaking the mass with urine is repeated, and the weekly soakings are continued until the whole has rotted down into a more or less soft mass of very rich, strong smelling humus. This material is invaluable for light soils, and a big barrowful per rod will be by no means too much to apply, in the late winter or spring. Fish heads and tails when buried in the soil without previous treatment take a considerable time to dissolve and thus are not so valuable.

Fish Meal.—This is obtained by drying any available fish offal from the markets, and usually the oil is got rid of by superheated steam. The resulting matter is ground to a fine powder and sold under this name. It is a phosphatic manure of no small value suitable for many crops, especially such as Globe Beet, Kohl Rabi, Celeriac, Swedes, Turnips, etc., and is suitable for most soils except those which are very heavy. It is best applied in the winter or early spring at the rate of 2–3 lb. per sq. rod and forked in. It is of no use as a liquid manure, but may be applied as a top-dressing and watered in.

Herring Refuse.—This is very abundant on the east coast at the herring season. It consists of a great variety of materials. There is sure to be a certain amount of bad fish in it, and with this is mixed up the sweepings from the harbour or dock where the herring pickers work. It can be dug into the land in its raw state or mixed with an equal volume of fresh manure, but in any case should be put on in the winter and not applied at a greater rate than about 3–4 cwt. per sq. rod.

Mussels.—These prove a valuable manure if properly treated. A quantity should be got together and either put through a poultry shell-crusher or put on a hard stone floor and crushed with a heavy lawn beater. The soft wet material which will result should be spread thinly on the ground in the early winter and dug in at once. It is useful for the grosser feeding crops as well as those fond of salt. It should be mentioned that the beds of young mussels give softer matter which may be dug in without this treatment. Mussels should not be allowed to rot away in a heap unless well covered with soil, as the stench they emit will be quite unbearable.

Oyster Shells.—Notes on the use of these will be found under SHELLS below.

Refuse from Canneries.—Where much fish is canned or cured refuse of value as manure will be abundant. It will contain not only an abundance of fish heads, tails, fins, etc., but also in many cases the outer skins, the spine and other bones, as well as the entrails. These last are the most valuable part, and while the stench of such decomposing matter will be quite impossible, if some can be had in a fresh state and be buried after being well mixed with an equal quantity of soil or manure, a highly valuable manure will result, suitable for use after about twelve months. This material can be used on most ground at the rate of 3–4 cwt. per sq. rod.

Shells.—These, after removal of the contained fish, are abundant in many districts at the coast, but their horticultural value is limited. Oyster shells or others of larger size are sometimes used for putting over the drainage holes in pots instead of crocks, and if the shells are ground

to a fine powder they may be used on land in the same way as chalk. In districts where stone is scarce they can be mixed in as an ingredient for concrete for pathways, etc. They can, of course, be dissolved in nitric acid in the same way as limestone or chalk to yield nitrate of lime, but as the process is somewhat laborious it is better to buy the prepared article.

Shrimp Refuse.—Where much shrimping is done and the resulting fish sold for the ever popular "Shrimp Teas," it is necessary for it to be sorted and cleaned first of all. The resulting material soon decomposes if not disposed of, emitting a painful, searching odour, and it is the custom in such districts for the council or cleansing department to collect it at least every seven days and burn it in their destructors. This is very wasteful, and it is a much better plan for fish sellers who have gardens to mix this material with one-eighth part of naphthalened soil and to bury it in their gardens for about six or eight months. The mass can then be dug out and spread on the vegetable garden at the rate of 1–2 cwt. per sq. rod, digging it in without delay.—E.

FLIES.

Flies include many kinds of insects. For instance, there are the sawflies, the houseflies, bluebottles, and the offal flies common on heaps of manure. It is about the last which we wish to say a word or two, and we prefix our remarks by saying that flies are most unnecessary as well as undesirable visitors to the garden.

The gardener should aim at cleanliness in everything and then flies will not be troublesome. His manure heaps if stacked otherwise than in the compost-yard should have a really good covering of soil; then the heaps will not breed flies and other filth. Rotted vegetable matter should not be left lying about, neither should fresh vegetable refuse such as cabbage leaves, etc. The pit in which vegetable matter decays should either be covered over with

boards, or the vegetable matter itself covered with lime and soil. Should flies in spite of these precautions still appear, water animal or vegetable matter with a weak solution of formaline to kill the eggs.

In glasshouses every precaution should be taken against allowing the flies to become a plague. Fly papers should be hung up right through the spring, summer, and autumn months, and the papers will need renewing frequently especially as they are apt to become less effective if the houses are always being syringed down.

The gardener should also clean out his ditches more often than he does, mixing the ditch sludge (which breeds billions of flies) with lime and earth. After it has been stacked for about nine months it can be dug into the vegetable garden, where it acts as a somewhat powerful manure.—E. T. E.

FLORISTS' FLOWERS.

In a sense all cultivated flowers are florists' flowers, but the term is meant to apply to certain species of plants which have, from their original forms, been evolved by the skill of the hybridist to a more comely appearance, more refined in shape, larger in size of flowers, more sweetly scented, or more highly coloured than occurred in their natural habit. In the majority of cases the evolution from a wild species to a florists' flower, brought about by a long series of intercrossings of chosen varieties, is simply an aggrandisement in form, size, or colour of the original wilding, as is the case in the Carnation, Rose, and Sweet Pea, but in several examples the hybridiser's skill has actually created what at first might appear to be a new flower, as for instance in the show Auricula, with its green, grey, or white edge, and in the complicated doubling of form as in the Japanese Chrysanthemum, or the Cactus, Pompon, and show Dahlia.

Propagation.—To propagate the named varieties of florists' flowers, cuttings, layers, or offsets are taken, as seedlings will not, or only seldom, perpetuate the fixed characteristics of the parents, and the vast majority of them will show a strong tendency to revert to a natural ancestry. Of course seedlings are the only source from which new varieties are evolved, but much skill and patience are required to advance still further the wonderful improvements already made. Long experience has shown that very high cultivation is required to achieve the best results in most of these specialised branches of horticulture, and the protection afforded by glasshouses has greatly assisted growers in the pursuit of their aims. Many florists' flowers, however, can be successfully grown in the open ground in a medium loamy soil enriched with farmyard or stable manure, using the former if the natural soil is light or too sharply drained, and the latter if of a clayey nature. For pot culture it is useful to have a stock of decayed turves at hand, as this, blended with old manure, leaf-mould, and a little sharp sand, forms a compost suitable for almost any plant.

Where a selection of varieties is given in the articles on each Florists' Flower in the list below, care has been taken to bring these as fully up-to-date as possible, but it should be borne in mind that hybridisers are still busy bringing out novelties,

sometimes improvements and occasionally not, and consequently catalogues of named sorts of flowers are changing from year to year.

List of Florists' Flowers.

The following is a list of the flowers usually considered florists' flowers. The present writer treats most of them in short separate articles; but a few, such as *Crocus*, *Daffodil*, *Dahlia*, *Gladiolus*, *Hyacinth*, *Pansy*, etc., are dealt with by other contributors :—

Alstroemeria.	Hollyhock.
Amaryllis.	Hyacinth.
Anemone.	Iris.
Antirrhinum.	Ixia.
Aquilegia.	Lachenalia.
Aster.	Lily.
Auricula.	Lobelia.
Begonia.	Paeony.
Calceolaria.	Pansy.
Canna.	Pelargonium.
Carnation.	Pentstemon.
Chrysanthemum.	Petunia.
Cineraria.	Phlox.
Crocus.	Picotee.
Cyclamen.	Pink.
Daffodil or Narcissus.	Rhododendron.
	Rose.
Dahlia.	Saxifrage.
Delphinium.	Sweet Pea.
Fuchsia.	Tulip.
Gladiolus.	Verbena.

FLOTE GRASS (*Glyceria fluitans*).—See *Glyceria*.

FLOWER GATHERERS. — See *Garden Tools*.

FLOWER GATHERING.

It is frequently said that "any one can gather flowers"—a true enough statement in one way, but as in everything else there is a right and a wrong method of working. More often than not the wrong way with all its resultant evils is followed, especially by ladies gathering the flowers for the home, or by children who are allowed to do so. There is no wonder that some gardeners are very jealous of other folks being allowed to gather the flowers from the borders, as lack of care in this direction frequently means spoilt plants; but alas, gardeners themselves at times are sinners too, possibly owing to their ignorance of the correct way of working.

The "plucking of flowers," so dear to all ladies and young folks, is something which wants speedily stopping. As a flower lover the writer has probably seen more plants mauled by this careless, thoughtless plucking than most people, indeed wherever he has gone he has seen the same thing. Schoolgirls come home after finishing their education, and are given the task by their parents of "doing the flowers," so they go out into the garden and pull and pluck to their hearts' content. Titled ladies, too, are apt at times to fall foul of their gardeners, who have to make good the devastation resulting from the plucking of choice blooms by the fair female hand. This is all by the way, however: we will now come to the point without further talk.

How to Gather.—Pulling or plucking of flowers should be left to the Stone Age when there were no steel cutting-tools, and every flower whether it be required for a buttonhole or for indoor decoration should be cut with a knife, a pair of scissors, secateurs, or, better still, a special flower-gatherer. In cutting with a knife, grasp the flower firmly with the left hand and cut it off with the right. When using scissors or secateurs on taller plants, cut in such a way that the flower will gently slip down on to the tool, and not drop on to the ground. This is not always possible with the two tools just named, but if a proper flower-gatherer is used, there is then no chance of the flower

falling to the ground and being spoilt, as the tool is constructed to avoid this.

Whatever tool is used, see that it is sharp. A dull tool will injure the plants, and make the flowers last less long in water. See also that the tool is perfectly clean, and always cut flowers with as long a stem as possible, since they can easily be shortened if occasion arises, but it is obviously impossible to lengthen them.

The best time for gathering flowers is a matter of opinion. Some well-known experts recommend cutting in the cool of the evening. This seems to the present writer to be a mistake. Being an early riser, out with no difficulty by six in the summer, he strongly urges flowers being cut between 6 a.m. and 7 a.m. with the dew upon them. Experience has shown that they last for a very long period when cut fresh in the early morning, longer than they do when cut in the cool of the evening after a hot day.

Some flowers are not suitable for cutting, and in order to avoid them we have included a list of *Flowers Unsuitable for Cutting* in this work.—E.

FLOWERING SHRUBS.

Undoubtedly flowering shrubs are quite indispensable in gardens where the charms of colour, form, and fragrance are prized, for no other class of subject which the gardener grows combines in a greater degree these desirable qualities. It is quite possible by a little study to have some shrubs in bloom nearly all the year round, and by the judicious arrangement and grouping of these plants most pleasing and wonderful effects are obtainable.

Shrubs for Walls.—First of all let us consider a few of the many purposes to which these delightful subjects lend themselves.

Some are splendid for clothing walls or fences, and of these we may mention: *Abelia chinensis* (delicate pink); *Berberidopsis corallina* (coral red); *Carpenteria californica* (pure white); Ceanothus in all its varieties; *Chimonanthus fragrans* (yellow); *Choisya ternata* (white); Cydonias in all their varieties, with orange, scarlet, blush, and white flowers; *Escallonia Langleyensis* (rosy-carmine); *Hydrangea quercifolia* (creamy-white); *Magnolia grandiflora* (white); and *Viburnums macrocephalum* and *plicatum*, with their clusters of white flowers and handsome foliage.

Rock Garden Shrubs. — Some flowering shrubs are seen at their best when planted in the rock garden, and splendid for this purpose are: *Azalea amoena* (crimson), flowering in early spring; *Berberis concinna* (pale yellow); *Berberis Wilsoni* (golden); *Cistus villosus* (rosy-purple); *Cytisus prostrata Andreana* (chocolate and gold); *Cytisus Kewensis* (creamy-white); *Cytisus purpureus* (purplish-red); *Daphne cneorum* (fragrant rosy-pink); *Daphne Blagayana* (ivory white); *Daphne fioniana* (pale rose); and *Genista anxantica* (golden-yellow).

Shrubs for Water Side.—Others such as *Berberis stenophylla*, the

Hydrangeas, *Leycestria formosa* (purple); *Spiraea Aitchisonii* (pure white); *Spiraea ariaefolia* (creamy-white); *Spiraea Lindleyana* (creamy-white), and most of the more vigorous growing flowering shrubs succeed on the verge of pool or pond.

Shrubs for Shade.—A collection of flowering shrubs for shady positions, including species that will thrive under trees, should contain *Berberis japonica* (fragrant yellow flowers); *Bupleurum fruticosum* (bright yellow); *Daphne Laureola* (yellowish-green); *Daphne Mezereum* (fragrant purple-red); *Hypericum elatum* (bright yellow); *Hypericum calycinum* and *H. Moserianum*, both of dwarf habit and with golden flowers; *Ligustrum japonicum* (creamy-white); *Olearia Haastii* (white daisy-like flowers); *Mahonia* or *Berberis Aquifolium* (golden-yellow); all varieties of the Ribes; *Rhododendron ponticum* (purple); all the Spiraeas mentioned above as well as the varieties *confusa* (white) and *Douglasi* (rosy-red); *Viburnum Tinus* (Laurustinus, white); *Veronica Traversii* (pale mauve), and all varieties of Weigelia.

Shrubs for Every Garden.—It is impossible in a short article to mention even by name one-half of the flowering shrubs worth growing, but let us for a moment consider a few of those which should be in every garden where space will allow. Most of those mentioned below are not rarities; indeed, most may be purchased for a very small outlay, but every one of them will repay the purchaser a hundredfold by its beauty year after year, as it grows to maturity.

First of all we must place the Almonds, sweet and bitter (*Amygdalus dulcis* and *A. communis*). These are so well known that little description is needed, but to see them at their best they should be planted in bold groups, and this remark also applies to the beautiful double flowering Peach (*Amygdalus Persica flore pleno*) with its rosy-red flowers.

We next come to the hardy Azaleas, and here it is a mistake to think they will grow only in peat, since they thrive exceedingly well in a good loamy soil, providing that the garden is not on a limestone subsoil. Their gorgeous colourings, orange, flame, salmon, softer pinks, and yellows, colours which never clash, make them well worth any extra trouble entailed in their cultivation.

Turning now to a different shrub, the Berberis, so many sorts are well worth growing that it is somewhat difficult to choose from the embarrassing number of varieties in cultivation. However, here are a few suggestions:

A charming little plant is found in *Berberis concinna*, a shrub 3 ft. high, with pale yellow flowers, and leaves of silvery grey on the underside. *B. Darwinii* is, of course, an old favourite, and its rich orange flowers followed by striking blue fruit are well known. *B. polyantha*, which grows 5 ft. high, retains its foliage until Christmas-time, and during November or December is a sheet of fiery scarlet. *B. stenophylla*, which grows about 6 ft. high, is simply smothered in spring with its flowers of brightest yellow, and makes a glorious hedge plant. *B. Thunbergii*, which rarely exceeds 1 yd. in height, bears yellow flowers, and in the autumn the foliage is gorgeous. *B. virescens*, growing 5 ft. high, is another fine subject for the autumn garden, and of stiffer and more upright habit than any of the other varieties mentioned; while *B. Wilsoni* is a dwarf but charming little shrub

with golden flowers and brilliant leaves and berries in autumn.

All these Berberis are fine subjects for massing, and a very fine effect may be obtained by planting a bed or bank with *Erica carnea*, or *Erica mediterranea hybrida*, and using as dot plants either of the varieties *B. Thunbergii*, *virescens*, or *polyantha*, the vivid autumn colouring of the Berberis showing to special advantage against the dull green of the heather.

As an autumnal flowering shrub, *Buddleia variabilis Veitchii* and its companion *B. variabilis magnifica* are without rivals; they provide a special charm on a bright day in September when their sweetly scented long panicles of lavender coloured flowers prove a great attraction to Peacock, Tortoiseshell, and Red Admiral Butterflies, of which great numbers may be seen flitting from flower to flower They grow about 10–12 ft. in height.

All the Ceanothus are charming, but *Ceanothus Gloire de Versailles*, a form of *azureus*, growing 8–10 ft. high, is quite the best, its rich blue flowers providing a lovely bit of colour from July to October; if planted with the beautiful hardy *Fuchsia Riccartoni*, a shrub with brilliant red flowers growing 6 ft. high, or with the Tamarisk (*Tamarix hispida*), with its feathery sprays of pink, a perfectly charming combination results.

The Japanese Flowering Cherries (*Cerasus japonica*), which grow about 30 ft. high, are amongst the best of the spring flowering shrubs; *C. j. H. Veitch* is usually recommended as the best, and an exquisite variety it is, with its rosy-pink flowers, but even better is the less common variety catalogued under the name of *Hesikura*, the flowers of which are a richer pink and are very freely produced. The young foliage of this sort is an additional attraction, being a delightful tint of soft bronze. The variety *Japonica Watererii* is a lighter pink than either of the preceding, though very lovely.

Amongst sweet-scented shrubs the Mexican Orange (*Choisya ternata*), growing 2 yds. in height, with its fragrant white flowers, stands pre-eminent, but excepting in warm districts this lovely evergreen should be grown against a south or south-west wall, as it is not perfectly hardy.

Another fragrant shrub flowering in the depth of winter is *Chimonanthus fragrans*, commonly but erroneously known as the Allspice. This too requires a wall upon which to train it, and it grows some 8 ft. high. Its yellow flowers with their exquisite scent are particularly pleasing in their season when frost and snow abound.

An evergreen shrub as hardy as the Laurel and with showy white flowers is the Rock Rose (*Cistus laurifolius*). This and the beautiful Gum Cistus (*Cistus ladaniferus*) are most desirable, and grow 4–6 ft. high. The dark reddish-brown blotches on the pure white petals of the latter shrub make it conspicuous anywhere.

Quite a number of our early flowering shrubs expand their flowers before their leaves, and the Cornelian Cherry (*Cornus mascula*), a shrub growing about 15 ft. high, is an effective example. Its yellow flowers are produced in great abundance in February, and for providing a mass of colour at this time of the year few shrubs equal it, especially as it thrives in any soil.

The Hawthorns (*Crataegus*) soon make small trees, and seem to thrive in any position; the double forms in pink, scarlet, and white are known to every one, but also deserving of cultivation are the varieties *C. Car-*

rierii and the Cock's-spur Thorn (*C. Crus-galli*), both of which grow 15–20 ft. high, and bear in the summer large white flowers, followed in the autumn with striking fruit and prettily coloured foliage. More of a curiosity is the celebrated Glastonbury Thorn (*C. Oxyacantha praecox*), a shrub growing 20 ft. high, and reputed to flower on Christmas Day, but which more frequently does so about mid-January.

Orange and scarlet flowers are always welcome, particularly in the early spring. The Japanese Quinces (*Cydonia japonica*), which grow 5–6 ft. high, brilliantly supply the needed colour, and are well worth growing, in bush form as well as in the form of wall plants. *C. Columbia* (carmine rose) and *C. Simonii* (blood red) are perhaps the best.

The Brooms (*Cytisus*) give us masses of colour which few flowering shrubs can equal. The White Broom (*C. albus*), *C. Andreana* (chocolate and gold), both about 6 ft. high, *C. Dallimorei*, with charming flowers of pale rose and mauve, and *C. praecox*, with its charming creamy-yellow flowers, both 4–5 ft. high, are well worthy of as much space as can be afforded in the garden; and a particularly pleasing way of growing them is on short stems as standards.

Most accommodating shrubs are the Deutzias, thriving as they do in any kind of soil and producing a mass of bloom in the early summer. *Deutzia crenata flore pleno* (double pink), *D. candidissima flore pleno* (double white), and *D. crenata Pride of Rochester* (pink and white), all about 6 ft. high, are as good as any of the many varieties; while *D. gracilis* (pure white, and of dwarf habit), growing as it does about 1 yd. high, is a fine variety both for the garden and early forcing.

The hardy Heaths (*Ericas*), which are so lovely, are given in an article to themselves, so that it must be enough to say here that they may be had in flower the whole year round providing the soil is suitable for their requirements. Much the same applies in the case of Rhododendrons which are, of course, indispensable flowering shrubs. These last are also dealt with separately. See article on *Rhododendron*.

In early spring no shrub is more attractive than *Forsythia suspensa*, growing 8–10 feet high, with its branches laden with golden bell-shaped flowers; and even more remarkably free-flowering, though scarcely so graceful in habit, is *F. intermedia spectabilis*, with flowers of a shade deeper yellow. Either of these shrubs grouped above a bed of Chionodoxas or Scillas makes a perfect picture.

No shrubs give a more delightful display in the autumn months than the Hardy Fuchsias. The variety *Riccartoni* has been mentioned previously, but *F. corallina* (carmine) and *F. gracilis* (crimson) are both highly recommended, and grow about 2 yds. in height.

Equally attractive in the winter is *Garrya elliptica*, a catkin-bearing plant of great beauty, growing 8–10 ft. high. The flowers are of soft grey and green tints, suffused with red. The plant is, perhaps, the most charming feature of a garden in mid-winter. Quite indispensable in the winter is the Japanese Witch Hazel (*Hamamelis arborea*), growing about 20 ft. high, with its quaint golden flowers produced in January. The forked branches of the latter shrub are used as divining rods.

Much greater use might be made of the shrubby Magnolias if it were generally known that they are amongst the hardiest of our shrubs. All they need is a sheltered position,

for their wax-like petals will not stand a blustering wind without injury. The Yulan Tree (*Magnolia conspicua*), growing 30 ft. high, with its large creamy-white flowers, *M. Lenne*, about 20–30 ft. high, rich purple, and also *M. Soulangeana*, growing 20–30 ft. high, with massive white flowers tinted purple, are the best of those of large growth. Of the smaller sorts *M. stellata*, which grows 2 yds. high and is the earliest to bloom, with its star-shaped flowers of purest white, provides a charming picture in March and April. If these Magnolias can be grouped with the Hardy Azaleas the effect produced will be superb.

The old Mock Orange (*Philladephus grandiflorus*), growing 10–12 ft. high, with its sweetly scented large creamy-white flowers, is well known, but a note should be made of the dwarfer hybrids of which *P. candelabre*, growing 3–4 ft. high, is conspicuous, not only in summer when a mass of bloom of pure white, but also by the warm colouring of its wood in winter-time.

All the Flowering Crabs (*Pyrus*) are beautiful. *Pyrus floribunda*, growing 20–30 ft. high, is rosy-crimson, and *P. floribunda atrosanguinea*, which is of similar height, is a deeper crimson. More than passing mention should be made of *P. Malus floribunda purpurea*, a flowering tree growing 20–30 ft. high, introduced recently, which may be expected to rival *Prunus Pissardi* in popularity when generally known. The flowers are a rich crimson, the young wood and foliage being a pleasing reddish-purple shade of colour, and the tree itself is of exceptionally graceful growth.

The best of the Flowering Currants is *Ribes atrosanguinea*, a shrub about 8 ft. high, bearing brilliant blood-red flowers. A really fine spring group may be had by massing this subject with either of the Forsythias previously mentioned.

Few shrubs equal and none excel the graceful and beautiful Rose Acacia (*Robinia hispida*), with its large pendulous racemes of rosy-pink flowers, and elegant fern-like foliage. Like all Acacias the branches of this plant are brittle and often injured by wind, so a sheltered spot is desirable when planting. It grows about 10–15 ft. high.

Blooming much later than the other Brooms that have been noticed, the Spanish variety (*Spartium junceum*), which grows 10–12 ft. high, makes a fine show in late summer and autumn with its bright yellow flowers and stems of rich deep green, and makes a splendid plant for massing. The same remark applies to *Spiraea arguta multiflora*, the best of all the shrubby Spiraeas, which grows about 4 ft. high. In the early spring this shrub, with its long pendulous branches smothered with pure white flowers, gives at a distance a resemblance to freshly fallen snow, and if bordered with *Muscari Heavenly Blue* makes an extremely pretty and dainty bed. *Spiraea Anthony Waterer* only grows 2 ft. high; with its rich crimson flowers it is of very different character, being compact and dwarf, and blooming from July until October. But of the many varieties to choose from this last should always form one of those selected.

Who does not love the Lilacs (*Syringa*), which delight in deeply dug and well-manured soil? There are varieties of the shrub to please everyone, both single and double, and ranging in colour from deepest purple to pure white. Amongst the best are *Alphonse Lavallee* (double lilac); *Charles X* (single reddish-purple); *Charles Joly* (deep double

purple); *Madame Casimir Perrier* (double creamy-white); *Madame Lemoine* (double white); *Miss Ellen Willmott* (double white); *President Carnot* (pale double lilac); and *Souvenir de L. Spath* (dark single red).

A more beautiful sight than a mass of bank of the Double Gorse (*Ulex europaeus flore pleno*) is difficult to find. Commencing to bloom as it does in March, it is at its best about mid-May, and its glorious golden flowers should brighten many an odd bank or corner, for the poorer the soil the better does this plant thrive and flower.

No list of flowering shrubs would be complete without the Veronicas, which bloom so continuously. Unfortunately they are not all perfectly hardy, but where they will succeed the newer hybrids should certainly be grown, and in more exposed positions, *V. Traversii*, with its pale lavender flowers, and *V. salicifolia*, a pure white, may be depended upon. Both average 4–5 ft. in height.

The Guelder Rose (*Viburnum Opulus*), with its snowball-like flowers, produced in June, and our old winter flowering friend the Laurestinus (*Viburnum Tinus*) are known to all, and so to most will be *V. plicatum*, growing 4 ft. high, and *V. macrocephalum*, 10–12 ft. high. Both bear large heads of white flowers; but a newer and most attractive species is *V. rhytidophyllum*; this would be worth growing for either its flowers, its foliage, or its autumn berries of brilliant red, and its handsome and distinguished appearance throughout the year entitles this plant to be described as an aristocrat of the garden.—E. A. J.

[It should be noticed that the names used in the above article are those which are well known to gardeners and the gardening trade, and therefore do not correspond with those following the new nomenclature adopted at Kew. Thus *Amygdalus* is in the new classification included in the genus *Prunus*, etc. etc.—EDITOR.]

FLOWERS BENEATH TREES.—See *WILD GARDENING.*

FLOWERS, FLORISTS'.—See *FLORISTS' FLOWERS.*

FLOWERS FOR INDOOR DECORATION.—Perhaps the most perfect of all decorations for the house is found in a well-grown flowering plant, which lends grace and beauty to the simple cottage home, whilst even the stately rooms of a palace would look bare without flowers. Not only so, but the fragrance of opening blossoms has, as science tells us, a distinct value to health, for they breathe out ozone.

In January, when cut-flowers are scarce, we have the early *Polyanthus Narcissi* from Italy, the two earliest of these being the *Double Roman* Narcissus and the *Paper White* Narcissus, both highly fragrant; and these are quickly followed by *Narcissus Grande Monarque*, a very fine flower; *Jaune Suprême*, in golden-yellow; *Scilly White*, and many others.

Van Thol Tulips in scarlet and yellow, can be slightly forced for Christmas; and they should be followed by a selection of the second-early tulips, of which *Cottage Maid*, *La Reine*, and *Proserpine* are amongst the most dainty.

Scilla sibirica, Roman hyacinths, snowdrops, and crocuses in various hues, are all available very early in the year without forcing; which the *Van Thol* Tulips alone will stand.

Many charming arrangements in bowls of fancy china, etc., can be made by raising those bulbs which show colour at the same time, and covering them with fresh moss in tepid water, with far more satisfactory

results than where the bulbs are grown throughout in the same pot; as, in that case, some flowers will appear before the rest, and the effect of the group is spoiled.

Lilies of the Valley (*Convallaria majalis*) can be obtained throughout the year by forcing; but it is difficult to induce the leaves to appear with the blossoms before February, even with retarded crowns.

Freesias in pure white, creamy-yellow blotched with orange, and various shades of pink, are most refreshingly fragrant, with a scent of mingled violets and cowslips. They are easily obtained in midwinter, if potted up in July and grown in the full sunshine out of doors until October, when they should stand on the shelf close under the glass of the greenhouse.

Pots of freesia bulbs can be started at intervals for a succession of these delightful flowers through the spring until the end of May, and their later blooms are often the finest.

In the early spring, too, we have many flowering shrubs which, if potted up in October, and forced very gradually, will make a rare show of bloom from February to May.

Deutzia gracilis, with elegant sprays covered with snowy blooms, is very easy to manage, only needing to be repotted every third year, and grown in the open air until it is placed in gentle warmth from January onwards.

White Lilac (*Marie Legrange*), and the purple variety *Charles X*, are the best for forcing; *Cytisus racemosus*, with its fragrant golden flowers; *Spiraea Thunbergi*; *Spiraea japonica*, in white or pale pink; *Amygdalus Persica fl. pl.*, the double crimsom almond; *Mackaya bella*, a lovely flower in lavender; the early Rhododendrons of the Himalayan and Caucasian groups (especially *R. nobleanum*, crimson, which flowers in February without fire heat) and the exquisite white rosettes of the Chinese plum (*Prunus sinensis fl. pl.*) may be obtained during the three first months of the year; and the Hydrangeas are available, by means of starting them in succession during at least six months.

The white *Hydrangea Dr Hogg* is one of the most useful and effective of room plants, for it will stand for several weeks in a shady place, where it retains the purity of its white blossoms much longer than in the sunshine. The pink *Hydrangea hortensis* and its blue variety are also handsome.

The beautiful azaleas of the East, *A. indica* and *A. mollis*, are perhaps the most perfect of decorative plants, in many shades of carmine, apricot, and crimson. They require plenty of tepid water at all times.

Pot-roses are not so often seen in a room as they should be; and yet they are amongst the most desirable of decorative plants. Pruned in January, and brought on very gradually in slight warmth, they will bloom in April and May.

During the summer there is, of course, a wide choice of pot-plants for room decoration, but those flowers which prefer a slight shade to the full sunshine, will prove the most satisfactory.

Tuberous Begonias, both single and double, do very well in an airy room; and the velvet-like foliage of *Begonia metallica*, with its pink and white flowers, is most effective. The dainty little plants of *Begonia Gloire de Lorraine* and its varieties are very popular in the autumn, and are most decorative.

The gorgeous blossoms of the Gloxinia too, although they need moist warmth until the buds are formed, will open well and last long in the semi-shade of a room.

Nicotiana affinis, handsome and fragrant as it is during the night, shuts its starry flowers and droops sadly when strong sunshine reaches it. But it can be induced to keep its blossoms open by means of growing it in a pot, which can be removed to the dark corner of the hall or the room in the evening, as soon as the blooms are open. They will not close in the shade for several days, when the plant should be returned to the open air until it has formed more flowers, and these are open. If kept in the shade too long the plant becomes weak and useless.

In the autumn there are various seedlings which are then ready to open their buds, such as *Primula sinensis*, in pink and white; *Cinerarias*, of which the blue varieties are the most desirable; and *Cyclamen persicum*, a plant which does remarkably well indoors if its foliage is kept free from blight by sponging with warm soap and water.

The waxen blossoms of the Winter Heath (*Erica hyemalis*) are very beautiful, and this plant is sold in large quantities in November for room decoration; but it needs careful watering, for its delicate hair-like rootlets soon become rotten in stagnant water, and yet the plant must not be kept very dry.

Poinsettias, with their flaming bracts in carmine, are at their best in December, when they may be grouped with the fine foliage and ivory spathes of *Calla aethiopica* (Syn. *Richardia africana*), the Arum Lily, with good effect in a room.

Perhaps the most festive of all pot-plants for Christmas decoration is *Libonia floribunda*, a neat little shrub with box-like foliage, which is completely covered with its fire-coloured blossoms in winter. It is nearly hardy, and needs but little warmth, but must have an abundance of water and a continual supply of rich food to do its best.

Zonal Pelargoniums, specially prepared for winter work, stand better in the dry warmth of a sunny sitting-room than many other plants. The variety *Henry Jacoby* is one of the best for winter-flowering; and the *Double Zonal* Pelargoniums have the merit of retaining their petals for a long time in winter, and are therefore very useful at that season.

The pretty hose-in-hose flowers of the winter-flowering Cactus, *Epiphyllum truncatum*, are available throughout the winter, and the effect of its hanging blossoms in a basket of fresh moss is decidedly good. Or it may be slipped into a bowl of olive-green china, where its brilliant tints in metallic crimson will be shown to the best advantage.—I. L. R.

FLOWERS FOR SEASIDE GARDENS. See ANNUALS, etc., in *SEASIDE GARDENS*.

FLOWERS FOR VERIEST AMATEURS.—See *GARDENING FOR THE VERIEST AMATEUR*.

FLOWERS: PACKING.—See *PACKING FLOWERS AND PLANTS*.

FLOWERS: SAVING SEED OF.—See *SEED SAVING*.

FLOWERS: TRANSPLANTING.—See *TRANSPLANTING*.

FLOWERS UNSUITABLE FOR CUTTING.—Although there are but few plants which are totally unsuitable for the decoration of our homes (if displayed in the right way) there are a certain number of flowers which suffer from some drawback to their general usefulness, either from their overpowering scent, from the shortness of their stems, or their heavy outline, etc.

These may be grouped as follows:—

Heavily Scented Flowers.—The most notable of these are:—*Brugmansia suaveolens, Choisya ternata,*

Citrus aurantium, Hedychium Gardnerianum, Hyacinthus syriacus, Lantana Sp., Lilium auratum, L. auratum platyphyllum, and *L. candidum,* Magnolias, *Philadelphus Sp., Stephanotis Sp.,* and some other hothouse plants not commonly cultivated.

Flowers Closing in the Daytime. —These also are unsuitable for cutting. The best examples comprise *Nicotiana affinis* and *Œnothera Sp.* Likewise those which close in the shade, such as *Eschscholzia Sp.* and *Nymphaea Sp.,* are also unsuitable.

Short-stemmed Flowers. — These are only suitable for laying on wreaths of Smilax or Climbing Fern (*Lygodium*) in the Indian style of table decoration. They include *Gentiana acaulis,* Pansies and Violas, and many dwarf alpine flowers, such as Saxifrages, Sedums, etc.

Flowers of Stiff Appearance.— In this section we include also flowers of heavy outline. Notoriously unsuitable for cutting are Double Begonias (tuberous), China Asters, Dahlias, Daisies, Gaillardias, Paeonies, and Zinnias.

Amarantus Sp., Antirrhinum Sp., Calceolaria Sp., Calendula grandiflora and other species, *Aloysia Sp.,* Cockscombs, *Impatiens Balsamina, Lachenalia Sp., Primula denticulata,* the taller Sedums, Sweet Williams, and *Trollius asiaticus* and *T. europaeus* are other flowers of this kind which are more or less unsuitable for cutting.—I. L. R.

FLUE DUST.—See *SOIL FUMIGATING.*

FLUEGGEA.—Now included in the genus *OPHIOPOGON.*

FLUELLEN (*Veronica officinalis*).—See *VERONICA.*

FLUORIDE OF CALCIUM. — See CALCIUM FLUORIDE in *LIME COMPOUNDS.*

FLUORIDE OF LIME.—The same as CALCIUM FLUORIDE. See *LIME COMPOUNDS.*

FLY POISON (*Zygadenus muscitoxicum*). See *ZYGADENUS.*

FOAM FLOWER (*Tiarella cordifolia.* Nat. Ord. Saxifragaceæ). —Quite a unique little plant is that correctly known as the FOAM FLOWER as above, with its pretty heart-shaped leaves and its white flowers borne in April. Only growing about 6 ins. high, it makes a gem for edging perennial borders, and is exceedingly useful in the rock garden. A very dry sunny situation should be chosen for it.

More often than not, however, if FOAM FLOWERS are ordered at a nursery one does not get the above at all, but a handsome herbaceous perennial known incorrectly by the above name, and known botanically as *T. unifoliata.* This bears lovely rose flowers in May or June, and grows about 1 yd. high. It succeeds admirably under ordinary border cultivation, is easily propagated by root division in March, and is best planted in the early spring.

FOAM FLOWERS (*Tiarella unifoliata*). These are distinct from *FOAM FLOWER,* as mentioned in that article.

FOENICULUM (FENNEL. Nat. Ord. Umbelliferæ).—Of the several species of this genus of hardy biennials, *F. dulce,* generally considered a variety of the COMMON FENNEL, is the most important. This is *F. officinale* of some authorities, and *F. vulgare* of Kew. Its culture, etc., is described under FENNEL in our article on *MEDICINAL HERBS.* It bears yellow flowers from June to August, and grows 2–3 ft. high. *F. piperitum,* popularly called ASSES' FINNOCHIO, is a less important species also with yellow flowers, but growing nearly 2 yds. high. This genus must

not be confused with *Ferula* on which a separate article appears (the English name of which is Giant Fennel).—J. F.

See also under Fennel in *Medicinal Herbs*.

FOENUM-GRAECUM.—Now included in the genus *Trigonella*.

FOLDING FURNITURE.—See *Garden Furniture*.

FOLIAGE PLANTS FOR ALL PURPOSES.—The popularity of foliage plants arises not only from the recognition of the claims of any peculiarly beautiful kind or species, but because of their unending variety, and their inclusion of a sufficient number of subjects from which may be chosen examples that may fittingly be utilised in every branch of decorative horticultural effort. Briefly to indicate to what extent this is true, it may be observed that there are foliage plants that may be employed purely as isolated specimens, as upon the lawn, or as room plants in the dwelling-house; others suitable for covering all sorts of walls and for hiding unsightly buildings; others of immense value in the rock garden; and others, again, that are indispensable in the greenhouse and conservatory. Moreover, though in connection with these subjects the production of flowers is generally regarded as of secondary importance, quite a number of them have in this respect considerably more than a negligible value.

For the Garden.—To commence with foliage plants suitable for permanent planting in the garden beds and borders, it is quite impossible, so wide is the range available, to do more than direct attention to a few that are specially valuable.

In trees or shrubs, perhaps there are none so attractive as the Japanese Maples. Striking enough indeed when showing their tender foliage, the latter in maturity has gained much added beauty. Golden-bronze and vermilion, orange and fiery scarlet, pea-green and cinnamon—all these shades and many more are offered, together with beauty of form and lightness and grace, presenting what has been justifiably described as an artistic feast from which nothing is lacking. *Acer palmatum atropurpureum, A. p. dissectum, A. p. dissectum ornatum,* and *A. p. septemlobum elegans* are some of the best. Sheltered situations are desirable, but bear in mind that sharp contrast which the plants should provide. For the further provision of autumn tints, regard should be had to such as *Mahonia Aquifolium, Rhus Cotinus, Rhus glabra, Andromeda arborea* (a tall-growing tree with pure white, bell-shaped flowers), *Crataegus prunifolia, Euonymus europaeus, E. atropurpureus,* Virginian Creepers (especially the self-clinging *Ampelopsis Veitchii*), and those wondrous climbers *Vitis Coignetiae* and *V. Thunbergii,* which in autumn assume the richest hues of yellow, orange, red, purple, scarlet, and crimson. For wreathing verandahs, old buildings, archways, pergolas, etc., the two last are climbing vines (deciduous) that cannot fail to be appreciated. When well established, *Vitis Thunbergii,* the more vigorous of the two, is a strong and free grower, quickly attaining imposing dimensions. Space will not permit of more than the briefest reference to the ornamental Conifers, such as *Abies pungens glauca pendula, Cedrus atlantica glauca, Cupressus lawsoniana,* the Retinosporas, Thuyas, etc., which are magnificent alike in form and foliage, but apt to be expensive, and are more particularly adapted to parks and pleasure grounds and

gardens of large dimensions. To be similarly classified is, perhaps, *Taxus baccata erecta aurea*, a yew of which the great feature is the distinct rich golden-yellow foliage of the current season's growth. Then there are the hardy Bamboos, the importance of which for garden decoration is now more generally recognised. Of these, *Bambusa Nagashima* is very ornamental, and only averages 1–2 ft. in height; *Phillostachys Borgana* is very handsome and vigorous; *Bambusa palmata* grows about 3–6 ft. high, with Palm-like leaves; *Arundinaria japonica* has tapering leaves a foot long, smooth and shining above and glaucous beneath; and *Phyllostachys flexuosa*, 6–8 ft. high, is of neat habit, and valuable for those whose space is limited. The Pampas Grass (*Gynerium argenteum*) should also be referred to at this juncture. This is perfectly hardy, and vigorous in growth, soon forming a bold and handsome clump, while the stately plumes, cut and dried in the autumn, are much appreciated for indoor decoration. *Centaurea macrocephala*, 4 ft. high, with yellow flowers, and the New Zealand Flaxes, *Phormium tenax* and *P. t. variegatum*, also *P. t. atropurpureum*, are other good subjects.

For the Rock Garden.—Foliage plants suitable for the rock garden are simply legion. Confining attention solely to those of a dwarf, shrubby character, a good selection should include *Berberis dictyophylla*, *Cassinia fulvida*, *Othonnopsis cheirifolia*, *Santolina Chamaecyparissus*, *Yucca filamentosa*, and *Veronica decumbens*, as well as many Cotoneasters, Ericas, and miniature Firs, Junipers, and Pines.

Greenhouse Plants.—For the greenhouse, the variety is no less rich. Every taste can be met, likewise the conditions of every kind of house. Ferns alone might be specialised in, and would not be exhausted even by a lifetime of study. [For these, reference should be made to *FERNS AND FERN GARDENING*.—ED.] Those noble subjects, the Palms, such as *Kentia Belmoreana* and *K. Fosteriana*, also *Chamaerops excelsa* and *C. Fortunei*, may be grown by all. The India-rubber plant (*Ficus elastica*) is another well-known favourite; so also the Norfolk Island Pine (*Araucaria excelsa*), *Grevillea robusta*, *Dracæna indivisa*, *Cyperus alternifolius*, the Castor-oil plant (*Ricinus Gibsoni*), and *Anthericum variegatum*, all of which are also employed, with the Palms and many Ferns, for dwelling-room decoration, and often survive a surprising amount of very rough treatment. Cannas, Centaureas (such as *C. candidissima* and *C. compacta*), *Zea quadricolor* (the variegated Maize), Brazilian Beet, and *Amarantus melancholicus ruber* are a number, out of many, that may be raised from seeds sown in a hotbed in spring. Oleanders and Brugmansias, the Scarborough Lily (*Vallota purpurea*), the wonderful Rex Begonias, as well as the rich-hued Crotons, Alocasias, and Caladiums, the decorative Coleuses, Aloes, Agaves, the Bertolonias (dwarf creepers, requiring moist heat, and best under a bell-glass), and, lastly, *Asparagus Sprengeri*, *A. plumosus*, and Smilax (including particularly *S. rubens*), with Maidenhair Fern, especially for cut foliage, must conclude a very incomplete selection, but one nevertheless entirely sufficient to demonstrate the great and attractive range from which the enthusiast may make his choice.

Treatment of Plants.—A final word may be added with reference to the treatment of foliage plants

in rooms. With these, cleanliness is the great essential, entailing the frequent sponging of dust from such as the Aspidistra, Aralias, Palms, India-rubber plants, etc., and at all times removing excess of water from saucers and vases, to prevent the souring of the soil and the furring of the pots. With regard to water, this should always be given as soon as the surface soil has become slightly dry, but never before, and never more than the soil will absorb. Further, where there is a greenhouse of any kind, it will do much to keep the room plants in health if they are regularly moved backwards and forwards from one to the other. *Phoenix rupicola* and *P. reclinata*, *Aralia Sieboldi* and its variegated form, *Latania borbonica*, with *Yucca recurva* and *Y. gloriosa*, it should have been mentioned, are plants that are of exceptional merit for rooms, while several of the subjects named in the paragraph on greenhouse plants are also indispensable for what is known as sub-tropical bedding in summer.—W. F. M.

[For further hints on room plants, reference should be made to the article on *Window Gardening*.—Editor.]

FON GUMI (*Elaeagnus macrophylla*).—See *Shrubs*.

FOOD FOR ALL CROPS.—See *Feeding Plants*.

FOOD GARDENING, Need of.

The national importance of gardening has been forced upon the attention of the inhabitants of the British Isles during the past few years to an extent that was not foreseen by the great majority of those who took part in the previous remarkable development of flower culture, and most gardeners have learnt that much more serious consideration must be given to the production of food crops in the future. We had, as in so many other directions, allowed ourselves to depend to a dangerous extent upon the importations of potatoes and other vegetables, whereas the recent increase of home production has shown us the possibilities of independence. With regard to these possibilities some indication is afforded by the estimates of the Food Production Department, who tell us that in 1918 there were upwards of 1,400,000 allotments, being an increase of nearly two-thirds within a period of four years, and the same authority estimates that each allotment on the average produces approximately one ton of food per annum. Further, it should be remembered that this estimate takes no account of the production of food crops in private gardens, which in the aggregate must bulk very considerably.

Apart, however, from the vital question of national safety in the matter of the home-grown food supply, there is the not uninteresting mercenary aspect. Why should we continue to send money abroad for produce we can quite well grow in our own gardens? In order to realise the extent to which we have been doing this, it will be both interesting and instructive to refer to the report of the Board of Agriculture for the year 1913, the last complete year of import returns under normal conditions. In that year the oversea supply of raw vegetables was, in value, the highest on record, reaching nearly £5,500,000. The imports of potatoes amounted to nearly 9½ million cwts., the largest total since 1904, when nearly 10 million cwts. were received; and the total imported supply of onions was over 9,000,000 bushels. Be it noted also that Germany was sending us increasing supplies, whilst large quantities were coming from the Netherlands, and that in addition

dried vegetables were coming in freely. These facts should be sufficient, without entering into details, to emphasise the need of food gardening upon the grounds of national safety and economy.

There are other and fairly obvious arguments to which brief reference only need be made. The difficulties and cost of transit will continue for some considerable time, so that the growth of vegetables in and around the centres of consumption is a desideratum, whilst those who have once grown their own will appreciate the greater freshness of the home produce as compared with that carried over long distances. But, apart from all such economic considerations, there is the very important effect of food gardening upon the physical and moral well-being of all who engage in it. Spade work, and the hours spent in close contact with Mother Earth out in the open air, are of immense individual and national benefit, and the countless city born and bred men and women who have recently taken up food gardening are now realising—to an extent they had never anticipated—a satisfaction of mind and body they could scarcely have attained by any other means.

FORGET-ME-NOT (*Myosotis.* Nat. Ord. Boraginaceæ).—About forty species of Myosotis have been described, mostly with blue, rose, or white flowers, and are annual or perennial. Several of the latter are grown and treated as biennials. They are sown in the open on a finely prepared seed-bed in June or July, transplanted into lines to give them more room, and transferred to beds in October. Old plants are also allowed to ripen seeds, and the self-sown seedlings treated as above. If potted up, then they will bloom in the greenhouse during the winter.

Some Suitable Sorts.—A number of splendid varieties have been raised, and those mentioned below are varieties of *Myosotis alpestris, M. dissitiflora,* and *M. sylvatica.*

Azure Blue.—A variety of *Myosotis alpestris,* producing deep sky-blue flowers from June to August. Height, 4–9 ins.

Barr's Rosy Gem.—A variety of *Myosotis sylvatica,* producing rose flowers from April to June. It forms compact bushes 10 ins. high.

Jewel.—A variety of *Myosotis sylvatica,* giving bright sky-blue flowers from April to June. It makes spreading bushes that cover the ground, and its height is 9 ins.

Pillar Forget-me-not (Syns. *Sutton's Gem* and *Myosotis stricta*). —An erect or columnar strain of *Myosotis sylvatica,* giving blue, pink, and white flowers from April to June. Height, 6–9 ins.

Ruth Fischer.—A compact variety, giving large pale blue trusses of flowers from March to May. It is a splendid pot plant. Height, 6 ins.

Star of Love.—A hybrid between *Myosotis dissitiflora* and *Myosotis*

sylvatica of dwarf compact habit, and producing large bright blue flowers from April to August. It is splendid for pot culture. Height, 5 ins.

Sutton's Bouquet.—A free-flowering strain of compact habit derived from *Myosotis sylvatica.* Its blue, pink, and white flowers are produced from April to June, and its height is 8 ins.

Sutton's Perfection.—An attractive strain of *Myosotis sylvatica*, producing large bright blue, rose, or white double flowers from April to June. Height, 9–10 ins.

Sutton's Royal Blue.—An early robust form of *Myosotis sylvatica*, producing large deep indigo flowers from April to June, in sprays suitable for cutting. Height, 12 ins.

Triumph.—A vigorous early flowering variety of *Myosotis sylvatica*, that makes a splendid pot plant to flower at Christmas. Grown outside, its bright sky-blue flowers are given from March to May, and its height is 9 ins.

Victoria.—A variety of *Myosotis alpestris*, producing large azure-blue flowers from June to August. Height, 4–9 ins.

White Lady.—A variety of *Myosotis sylvatica*, producing white flowers with a small yellow eye in April and May. Height, 10 ins.—J. F.

New Variety.

Souvenir of William Walton.—This bears extra large, bright blue flowers, and is a variety with a future.

FOXGLOVE (*Digitalis.* Nat. Ord. Scrophulariaceæ).—Some eighteen species of biennial and perennial Foxgloves are known, though comparatively few of them are grown to any extent. The Common Foxglove (*Digitalis purpurea*) is a well-known woodland plant, and is thus useful for the wild garden, for shady borders, and for margins of shrub borders. It is a plant of decided medicinal value, and reference should be made to our article on *MEDICINAL HERBS* for further particulars.

Biennial Border Species.—The four sorts described below are exceedingly useful, but the second is the most showy. They may all be raised from seeds sown in an open or half-shady part of the garden in April and May, but it is advisable to thin out or transplant the seedlings when quite small to get large plants for beds and borders.

Digitalis alba.—This bears white spotted or spotless flowers from June to September, and grows 3–5 ft. high.

D. gloxinæflora (GIANT SPOTTED).—This sort is available in many colours, and the flowers, which resemble Gloxinias on account of the large spots upon them, are produced from July to September, on plants 3–5 ft. high.

D. monstrosa.—This sort may be had in various charming colours, and its large bell-shaped top flower borne from July to September is distinctly attractive. Its height is 3–5 ft.

D. purpurea (COMMON FOXGLOVE).—This is a well-known purple sort flowering from July to September, and growing 3–5 ft. high.

Perennial Border Species.—These are of the easiest culture in any good garden soil. They merely require to be kept clean by hoeing the beds and borders. Most of them may be increased by division of the roots in the autumn or spring, but all can be reared in quantity from seeds. Most of the perennial sorts are curious and interesting, though not so showy as the common Foxglove. We recommend the following selection :—

Digitalis ambigua (Syns. *D. grandiflora, Milleri,* and *ochroleuca*).—This bears large buff-yellow flowers, which may vary in their shades. The plant blooms in July and August, and grows 2–4 ft. high.

D. dubia.—A synonym for *D. media,* which see.

D. ferruginea (Syn. *D. aurea*).—This short-lived perennial bears very numerous small rusty brown flowers in July and August, on plants 4–6 ft. high.

D. laciniata.—This sort bears small yellow flowers in June and July, and grows 1½–2 ft. high.

D. lanata.—This sort bears brownish-white or grey flowers, with a white or pale purple beardless lip, from June to August. Its height is 2–3 ft.

D. lutea.—This bears numerous light yellow flowers in July and August, and grows 2 ft. high.

D. mariana.—This bears pretty rose flowers from June to August, and grows 1½ ft. high.

D. media.—(Syns. *D. dubia* and *D. minor*).—This bears large pale purple flowers in June and July. Height, 6–9 ins.

D. orientalis.—This species produces small white flowers in June and July, and grows 1½ ft. high.

D. Thapsi (MULLEIN FOXGLOVE).—This attractive sort bears large purple flowers with red spots within, from May to August, and grows 2–4 ft. high.

D. tomentosa.—This useful sort produces large red flowers from June to August, and grows 2–4 ft. high.—J. F.

See also *DIGITALIS, MEDICINAL HERBS,* and *WATER GARDEN: PLANTS FOR THE.*

FRAGARIA (Nat. Ord. Rosaceæ). From this genus have originated the delicious GARDEN STRAWBERRIES we are all so fond of. *F. elatior* is popularly known as HAUTBOIS, while *F. vesca* (Syn. *F. mexicana*) is the well-known WILD STRAWBERRY. For details of culture and varieties to grow see article on *STRAWBERRIES.*

FRAGRANT PINK (*Dianthus fragrans*). See *DIANTHUS.*

FRAGRANT ROSES.—See ROSES FOR FRAGRANCE in *ROSES FOR ALL PURPOSES.*

FRAGRANT TEA ROSES.—See under TEAS in *ROSES FOR ALL PURPOSES.*

FRAME CUCUMBERS.—See *CUCUMBERS* (*FRAME*).

FRAME MELONS.—See *MELON.*

FRAMES.—See *GARDEN FRAMES* and *GREENHOUSES AND FRAMES.*

FRANCOA (BRIDAL WREATH. Nat. Ord. Saxifragaceæ).—This is an acquisition to any greenhouse and of the easiest culture. Sow the seed in March in slight bottom heat. A dry sandy loam suits it best. Temperature required, 40–45° F.

Greenhouse Species. — *Francoa ramosa.*—Pure white blooms, freely produced on long branching spikes. Flowers from July to August. Height, 2 ft.

F. sonchifolia.—Purple. Flowers from July to August. Height, 2 ft.

FRASER'S SILVER FIR (*Abies Fraseri*).—See *TREES.*

FRAXINELLA (*Dictamnus.* Nat. Ord. Rutaceæ).—We do not know which is the most common name for this excellent hardy perennial, Burning Bush or Fraxinella. Botanically it belongs to the genus Dictamnus. An attractive plant at all times and specially when in bloom; it is inflammable, as many know to their cost who have thrown a lighted match, after lighting their pipes, into a clump or bed of this. We remember seeing a magnificent lot of it in St. John's College Garden, Oxford, when we were there last year.

Culture.—This is not a matter of any difficulty. The plants will succeed in any ordinary rich garden earth in a sunny or very lightly shaded spot. They dislike wet sunless spots, however. It is best to buy plants of them and plant them in February or March, as plants raised from seed are at least two years before they flower and sometimes take longer still. Propagation may be effected also by division of the roots, though this is not as easy as it is in the case of some plants.

What to Grow.—We recommend the following as being suitable sorts for the garden :—

Dictamnus albus.—This is a white sort blooming in May and June, not so showy as some, averaging about 3–4 ft. in height. The following are varieties of it :—

D. a. Fraxinella (FRAXINELLA).—This sort bears brilliant red or crimson flowers from June onwards, and averages about 1 yd. in height.

D. a. himalaicus.—This is a purple sort not as good as the former variety. It blooms freely, however, in May and June, and averages about 2 ft. high.

D. a. purpureus (BURNING BUSH).—This is probably the most popular and attractive sort of all. It bears reddish or purplish flowers throughout the summer, and these readily catch fire at night, if a spark falls on them. The plant averages about 1 yd. in height.

D. a. tauricus (Syn. *D. angustifolius*).—This is a very tall sort producing light purple flowers in May or June. It often exceeds 2 yds. in height.

D. angustifolius, *D. Fraxinella*, *D. himalaicus*, *D. Limolayensis*, *D. purpureus*, and *D. tauricus* are not now recognised as distinct species, but as varieties of *D. albus* above.

FRAXINUS.—For the best species see *TREES.*

FREESIA (Nat. Ord. Iridaceæ).

Freesias are bulbous plants with small sword-like leaves, and tubular flowers arranged in a row at right angles to the top of the stem. They come from South Africa and, like Lachenalias and Nerines, are just not hardy. They are, however, easily cultivated in pots in cool greenhouses, and as the greater number of the varieties are sweet-scented, they are highly prized either for cutting, or as pot plants for the house from Christmas to the end of March, which may be taken to be their normal flowering season under glass in the British Isles.

Since the Jubilee Exhibition at Haarlem in 1910, numerous coloured varieties have been placed upon the market. The present writer believes there is a great future before them, if, as seems likely, brighter and more decided colours can be obtained, and the delicious fragrance of the old *Freesia refracta alba* retained.

Culture.—Freesias should be potted between the first of August and the middle of September; after this date the results are never quite so satisfactory as from bulbs potted earlier. Any good, rich, light porous soil suits them, with plenty of drainage, and 5–6 inch pots are the most useful sizes. Plant the bulbs 1 in. apart each way, so that ½ in. of soil covers the top of the bulbs. Many growers when the potting is done early in August, stand the pots out of doors on a hard bottom, and only house them or put them in cold frames when frost comes. It is best, however, to put the coloured varieties at once in cold frames or in a cool greenhouse, as their bulbs seem to need just a suspicion of warmth to start them, otherwise some may remain dormant a whole year. Do not plunge the pots overhead in either fibre or ashes.

The temperature at which they do best ranges from 45° F. at night to 60° F. on a sunny day. They like plenty of air, and repay feeding once or twice a week with some weak stimulant, when the flower stems show themselves, but not before. This should be continued until the foliage starts turning yellow, after which water must be gradually withheld till the foliage is quite dead. The pots should then be put in some dry, sunny place to get the bulbs well baked. They may be shaken out and graded in July, ready for planting again in August.

Raising Seedlings.—This is easily done. The varieties cross freely with one another; but hand fertilisation is essential for the best results. The seed will be ripe in June, and may be sown in 7–8 inch pots in July or early August under glass, in gentle warmth if possible, giving abundance of light and air. Grow them on all the autumn and winter in the same way as other Freesias, but be very sparing with the application of stimulants, if any are used at all. Be most careful when shaking the little bulbs out to get all the bits that belong to each one together. To facilitate this, every seed when sown should be ⅛ or ¼ in. every way from its neighbour.

Varieties.—The following selection contains the best sorts, all of which flower freely from January to March:—

Freesia Abundance.—A mauvy-rose sort turning to rose with age, and growing 18–20 ins. high.

F. Bluebeard.—A soft bluey-mauve sort. Height, 15 ins.

F. Buttercup.—A deep yellow sort. Height, 15 ins.

F. Canary.—A pale yellow sort. Height, 15 ins.

F. Chapmanii.—A rich, deep yellow. Height, 15 ins.

F. Contrast.—A white sort with conspicuous orange blotch. A very attractive variety about 18 ins. high.

F. Dainty.—A tall rosy-mauve sort. Height, 18–24 ins.

F. La Chamante.—An apricot-rose sort. Height, 15 ins.

F. Leichtlini major.—A cream sort with yellow marking. Height, 15 ins.

F. Purity.—A pure white sort. Height, 15 ins.

F. refracta alba.—A white sort with yellow blotch. Height, 15 ins.

F. Rosa Bonheur.—A rosy sort. Height, 18 ins.

There are several people in

England now working on Freesias, so in a short time new colour varieties will be in commerce. Messrs. Herbert Chapman, Dalrymple, & Jacob have already received awards from the R.H.S. for their seedlings. Several firms sell seedlings in mixture. These, if a good strain is guaranteed, give pleasing results.

J. J. & E. T. E.

NEW VARIETIES.

Freesia Bartley Goldfinch.—A deep yellow sort with an orange blotch.

F. Bartley Mauve.—A deep mauve sort with dark veins.

F. Bartley Rose.—A bright rose sort with a white throat.

F. Chapmanii aurantiaca.—A rich yellow sort shaded with orange.

F. Excelsior.—An early variety with creamy-yellow flowers on which is a darker blotch.

F. La France.—An extra large mauve sort with a creamy-white throat.

F. Merry Widow.—A soft lavender sort with large flowers.

F. Miss Elwes.—Clear salmon-pink flowers.

F. Rose Beauty.—A deep rose sort with a white throat.

F. Sweet Lavender.—A pale lavender variety.—W. J. C.

FREMONTIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

FRENCH BEANS.—See CLIMBING FRENCH BEANS in *BEANS*.

FRENCH GARDENING.

With the help of standardised frames and lights, also of bell-shaped glasses or cloches and an ample supply of horse manure, gardeners can obtain from the last week in February to the end of the year a large succession of vegetables from a comparatively small area of ground, which rarely exceeds three acres.

The system consists :—

First, of a few varieties of vegetables grown together, and at the same time, either under glass or outside. They are so selected that one crop comes to maturity before the other requires more space for its natural development.

Secondly, of the planning of the year's work, so as to utilise constantly and to the best advantage right through the year all the frames and bell-glasses.

To do this the plan generally adopted is as follows : From August to December, plants of Cauliflowers and Lettuces are raised and grown to supply the requirements of the spring work, which begins with the new year by the making of hotbeds and cold beds for a supply of Carrots, Cauliflowers, Lettuces, Radishes, and Turnips for the market from the last week in February till late in June.

Early in May the frames and bell-glasses will be removed from the above-named crops, which will then complete their growth in the open air, and the material will be at liberty for such crops as Beans, Cucumbers, Melons, and Vegetable Marrows.

The vegetables grown under that system are divided in two classes :—

(*a*) "Main crops," such as Cabbages, Carrots, Cauliflowers, Cucumbers, Melons, Turnips, which require one to three months to fill up the room necessary to their full growth.

(*b*) "Catch crops," including Endive, Lettuces, Radishes, Spinach, which are either sown or set among the main crops, and are ready for consumption before these are fully established.

The success of French Gardening depends chiefly upon each crop being ready within its allotted time, or, failing this, it would mean the deterioration of the crop grown with it, and spoil the routine of the work for the season. Each crop must be

kept in perfect growth from sowing onwards, and is either transplanted or thinned out when it is needed.

Such results can only be obtained by great care in all practical details of cultivation such as: Ventilation, Sheltering, Watering, and above all scrupulous cleanliness in the work.

Material.—The chief appliances used in this method of gardening are:—

First, the Frames. These are shallow structures; the front is 7 ins. wide and the back 9 ins., made to hold 3 lights $4\frac{1}{8} \times 4\frac{1}{2}$ ft. They are easily portable and are always set in rows of five each.

Secondly, the Bell-glasses or Cloches are $18\frac{1}{2}$ ins. in diameter, and 126 set in three rows occupy the same space as a row of five frames.

Laying Out of a Garden.—The frame is the basis in the planning of the ground. This is divided in plots 65 ft. long, each being sufficient to accommodate rows of five frames.

The width of a plot rarely exceeds 60 ft., to save labour in the carrying, and a 4-foot path is allowed between each plot. It is essential to reserve a sheltered corner for the nursery beds for rearing all spring seedlings. The plot allotted for the hotbeds must be conveniently near to the manure stack, and it should be well drained. The quarters for the Cucumbers and Melons, and also the rearing of all Cauliflowers and Lettuce plants through the winter, are changed every year for the benefit of crops which will be grown subsequently in those quarters.

Manure.—The only manure suitable for this system of culture is horse straw manure. It is used: First, as a means of heat production for the benefit of the early crops in the spring. Secondly, after the decay has set in in the early summer it becomes humus for the crops from June till late in the autumn. Thirdly, during the winter it is broken up, and under the action of the weather pulverises into a fine compost, which is used as soil for the crops the following year.

The manure should be collected all the year round and put in stack. Care is taken to facilitate the escape of gases emanated through fermentation by placing long wood funnels in the middle of the stack. The manure in the stack gets quite dry, and when making the hotbeds it is mixed with fresh; the two together produce a steadier and more constant heat than fresh manure alone.

Hotbeds.—These beds are started from the middle of January; they are built with an equal quantity of dry and fresh manure, which should be well mixed together. Eight to ten tons are necessary to construct a bed 10 ins. thick, 5 ft. wide, and 67 ft. long, sufficient to accommodate five frames or one hundred and twenty-six bell-glasses. The inside of the frames is filled with the decayed manure obtained from the beds made the previous year. A 10-inch path is allowed for between each row of frames, and this is filled with fresh manure every fortnight to maintain an even temperature in the frames.

A different method is practised for Cucumber and Melon beds, as these are only wanted early in May. A trench $2\frac{1}{2}$ ft. wide and 8 ins. deep is dug out and filled next with good manure. The frames are then placed over the trench, and they are filled with the soil from the next row.

At the end of the season the manure in these beds is broken up two or three times till it is fine. Two-thirds of the quantity is kept as soil for the following year's work, and the remainder is available for manuring or top-dressing the beds in the open ground. It is a very

rich compost and quickly assimilable by all kinds of crops.

Cold Beds.—To obtain a constant succession of produce from a French Garden, one-third of the material is reserved for what is known professionally as *cold work*. On a plot of ground heavily manured and well dug before Christmas, frames or bell-glasses are set the same way as they are on the hotbeds. The same rotation of crops is sown or planted, and these receive similar treatment. Though the produce is later, it is superior in quality to that grown on hotbeds, and this is due to the plants growing more naturally. This method is very remunerative, and its success depends entirely upon the quantity of decayed manure available for filling the frames.

THE YEAR'S WORK.

The plan of work generally adopted by the majority of growers is as follows :—

August 1st to 8th.—Sow in the open Spring Cabbage and Onions. Sow in frames Little Gott Cabbage Lettuce for use before Christmas.

September 1st.—Plant Little Gott Lettuce in frames (150 plants to each frame).

September 15th.—Sow in frames Snowball Cauliflower for hotbed work and All Year Round Cauliflower for cold work.

October 1st.—Sow in frames All Year Round Cauliflower for growing in the open ground. Plant Spring Cabbages in the open ground.

October 5th.—Sow in frames or under bell-glasses Little Gott Lettuce for hotbed work.

October 8th to 12th.—Sow Passion Lettuce (Black Seed) for cold work, and Paris Grey Cos Lettuce for bell-glasses on hotbeds.

October 10th to November 10th.—Prick out all Cauliflowers in frames (750 per frame), and Lettuces under bell-glasses (30 plants per bell-glass), in their winter quarters.

November 15th. — Sow Passion Lettuce very thinly in frames for growing in the open.

November and December.—Break up all manure beds and prepare the ground for the cold work.

January 1st to 15th.—Sow broadcast in the cold bed Early French Breakfast or Wood's Frame Radish, also Chantenay Carrot, setting over Passion Lettuce (75 plants per frame).

January 15th to February 28th.—Make up the hotbeds for frames and bell-glasses. Sow broadcast Early French Breakfast Radish and Early Parisian Carrot in the frames setting over Little Gott Lettuce (150 plants per frame). Chantenay Carrot is sown on the beds for bell-glasses, and three Little Gott Lettuces and one Paris Grey Cos Lettuce are set under each bell-glass.

February 15th to March 15th.—Sow on hotbeds in the nursery quarters All Year Round Cauliflower and Chemin or White American Celery, also in cold frames Paris White Cos Lettuce for planting outside.

March 15th to 31st.—Plant Snowball Cauliflowers on the hotbeds (24 per frame), also All Year Round Cauliflower for the cold work (15 per frame). Sow Snowball or Half-long Turnip on hotbeds. (When Turnip is sown on hotbed a batch of Lettuce is first grown from plants set in January, and the Turnip is sown after the marketing of that crop.) Plant Passion Lettuce and Cos Lettuce outside. Sow the first batch of Cantaloup Melon and Tomato in the nursery beds.

April 1st to 15th.—Sow in drills Kidney Beans and Turnip in cold frames. Plant Cauliflowers outside. Sow the main patch of Cantaloup Melon, and also Vegetable

Marrow in the nursery beds. Sow the main batch of Cauliflowers and Broccoli for autumn supply outside.

April 15th to 30th.—Sow Beetroot and Turnip outside.

May 1st to 8th.—Sow the first batch of Telegraph Cucumber and the last lot of Cantaloup Melon in the nursery beds.

May 8th to 31st.—Make up and plant the Melon and Marrow beds. Prick out the Celery plants. Plant the spring sown Cauliflowers and also Tomatoes in their final quarters. Sow the last batch of Cucumbers in the nursery beds.

June 1st to 20th.—Plant the last batch of Melons. Make up the beds for Cucumbers. Plant the main batch of Celery in the open ground.

June 20th to 30th.—After the marketing of Cauliflowers grown on the hotbeds, the beds are forked over lightly and the space is filled with White Celery or another batch of Cauliflowers.

July 1st to 15th.—Plant the last Cauliflowers.

July 15th to 31st.—Sow Chantenay Carrot on the old bell-glass beds, also the last Kidney Beans outside; these will have the shelter of the frames to complete their growth early in September.

SOME PRACTICAL POINTS.

Experience has taught French gardeners:—

First: Cauliflowers must be sown in rich soil and not before September 15th, or they will show bud too early in the spring.

Secondly: If Cauliflowers are sown after May 8th they will not come to maturity before the frost.

Thirdly: Red varieties of Celery are unsuitable for planting on the old hotbeds.

Fourthly: Tomato plants must be stopped before July 15th in order to ripen all the fruits.

Fifthly: Turnip sown under glass must receive ventilation daily.

Sixthly: Turnip sown outside before April 8th rarely gives satisfaction.

Seventhly: Six weeks are necessary to rear Cucumber or Melon plants suitable for setting in their final quarters.

Eighthly: Endive must always be sown under glass before June 15th, and should germinate within 60 hours, or it will run to seed.

Ninthly: Bean seeds should hardly be covered to ensure an even germination.

Tenthly: When pricking out any kind of seedlings, all weak, drawn, or overgrown plants are disregarded.

DISEASES. — Vegetables grown under the French method are practically immune from most diseases and insects so prevalent in ordinary gardens: this is probably due to the constant activity of the plants and the high fertility of the decayed manure, which render them sufficiently strong to resist such attacks. Exception must, however, be made for the mildew, *Peronospera ganglioniformis*, which fungus destroys a large quantity of Lettuce plants in their winter quarters. No effective cure is known so far, but as a preventive, it is advisable to scatter ½ lb. of powdered Copper Sulphate to every bed (65 ft. long) a fortnight previous to the transplanting of the young seedlings. Should the disease appear, the attacked plants are covered with flowers of sulphur, and though it kills them, it checks the disease from spreading.

Lettuces set either in the cold work or outside outgrow the mildew, but care must be taken to set only healthy plants on the hotbeds.

FRITILLARIA. — See *CROWN IMPERIAL* and *FRITILLARY*.

FRITILLARY (*Fritillaria*. Nat. Ord. Liliaceæ).—Fritillarias compose a large family of bulbous plants with flowers of varied form, size, and colouring. The striking characteristic which runs through them all is their nodding or drooping bell-shaped and generally chequered flowers. The best and widest known species is the old *CROWN IMPERIAL* (*F. Imperialis*), on which a special article appears. *F. Meleagris*, the well-known SNAKE'S-HEAD FRITILLARY, is a native of Great Britain, and used to be abundant in the meadows at Oxford. Both it and *F. latifolia* have given rise to numerous colour forms. As a rule all the different varieties and species flower in April or May.

Culture.—Pheasants are very fond of the bulbs of *F. Meleagris* and other varieties: thus where these birds are plentiful, culture should not be attempted. Any good garden soil suits them. Some of the smaller ones, such as *F. armena* and *F. aurea*, are very useful for warm places in the rock garden. The varieties of *F. Meleagris* may be naturalised in thin woodland where the shade is not heavy. In such positions the bulbs should be put 6 ins. deep. The varieties of *F. latifolia* are nice in pots.

Species and Varieties.—Some of the best are briefly described below :—

Fritillaria armena.—This is a yellow-flowered species which blooms in April, and grows 6–8 ins. high. There is also a red variety.

F. aurea.—This bears rich chequered golden-yellow flowers, which open in April. It grows 8–10 ins. high.

F. latifolia.—This has broader leaves than *F. Meleagris*, otherwise it is very similar. The flowers are chequered and of some shade of green, yellow, brown, or purple. They appear in April or early May, on plants 10–12 ins. high. There are many colour variations of which some of the best are : *Beets* (bronze-red and yellow); *Erasmus* (yellow and brown); and *Lola Montez* (green and purple). The names, however, are very unreliable.

F. Meleagris (SNAKE'S-HEAD FRITILLARY).—This has chequered flowers which vary from a dull purple to pure white, and which are usually produced in April or early May. The average height is 12–15 ins. As in the case of *F. latifolia* there are numerous named colour varieties, but it is sufficient to mention by name *F. Meleagris alba*, which bears pure white flowers.

F. pallidiflora.—This bears pale yellow flowers in May, and grows 12–14 ins. high.

F. pudica.—This bears yellow

flowers in April, and grows 6 ins. high.

F. pyrenaica.—This is a handsome plant with rich plum-coloured chequered blooms which expand in May. It grows 15–18 ins. in height.

F. recurva.—This has orange-scarlet chequered flowers in May, and grows about 12 ins. high.

F. verticillata (Syn. *F. Thunbergii*).—This bears cream-coloured flowers in May, and grows about 12 ins. high.—J. J. & E. T. E.

FROG HOPPER.—See under CUCKOO SPIT in *INSECT PESTS.*

FROST GRAPE (*Vitis vulpina*).—See *CLIMBING AND TRAILING PLANTS.*

FRUIT BARK BEETLES.—See *INSECT PESTS.*

FRUIT BORDERS.

These should be thoroughly well prepared before any planting is done—the best mode of procedure being to trench them a yard deep. Plenty of old manure should be worked in well down, and artificials suitable for the season and soil (see article on *ARTIFICIAL FERTILISERS*) should be added to the two top spits.

Fruit borders outside fruit houses should be cropped very lightly, and certainly not with a gross-feeding crop such as potatoes. Hardy herbaceous perennials with fibrous roots may be planted thereon, also surface-rooting vegetable crops.

All fruit borders should have a heavy dressing of old manure lightly forked into them every spring and should be kept scrupulously free from weeds.

FRUIT BOTTLING AND PRESERVING. — The practice of bottling one's own fruit at home is an art which has, unfortunately, fallen almost into disuse in this country; but the past war has opened our eyes to the many economies hitherto little practised, and this is one of the operations which may well be revived. Much fruit has been wasted by lack of knowledge in this direction, and it is hoped that the hints which follow may prove successful in preventing waste, and be a means of providing fruit to all households in the winter and at times when it is most difficult and exceedingly expensive to buy. There are three essentials in this work: first, cleanliness; second, strict attention to details; and thirdly, common sense.

Everyone knows that fruit will quickly go bad if it is not consumed within a certain definite period, and most people know that if it is put into bottles in the ordinary way it will also go bad very quickly; but if the bottles are *sterilised*, namely, heated up to a temperature at which all the germs contained are killed, and so that the air is partly driven out, the fruit keeps perfectly, and it is on this principle that fruit bottling depends.

Apparatus Required. — The idea among amateurs that fruit bottling is very expensive has but little foundation in fact. Simple apparatus is required, and once this is obtained it will last for a long period. First of all, the purchase of proper vacuum bottles is found to be the cheapest and most satisfactory, as they last a lifetime. These are made in several patterns in glass, with lid and rubber ring held in place by a metal screw or clip.

When we have purchased our bottles we need what is called a *steriliser* in which to heat them. Now a proper steriliser, fitted with a false bottom, thermometer, etc., is a very useful possession, but where expense must be considered, a deep boiling-pan, fish-kettle, bucket, or laundry copper will do equally well, with one or two small

alterations. Whatever is used for sterilising the fruit, it should be deep enough to allow the bottles to stand upright and for them to be almost submerged in water. If the steriliser is a home-made one, the false bottom must on no account be forgotten, as otherwise the bottles are sure to crack. This is easily made by tacking together strips of wood and placing them on the bottom of the pan, to form a small platform, and thus the jars are prevented from coming into direct contact with the heated metal of the pan.

The next essential is the *thermometer*, and no fruit-bottling should be attempted without it. An ordinary dairy thermometer marked in plain English figures is the best, since no mistakes can then be made in reading it. A small hole should be cut in the lid of the steriliser, a cork fitted into this, and the thermometer let through the cork by means of boring. The thermometer should be let midway into the pan, so that it can be easily read without opening and thus cooling the contents of the steriliser.

Fruit Bottling in Water.— The first method of bottling fruit which may well be described, is the water method, and for this as for any other method the jars should first be washed, and placed side down in a vessel and covered with cold water. This should slowly be brought to the boil, and the sterilising continued for ten minutes, after which the bottles are dried and inverted. The fruit for this method, as for any other, should always be chosen when it is perfectly dry and fresh. It must not be overripe. Grading is advisable, and it is then packed carefully and tightly into the bottles, filling them right up to the top. When packing any hard fruits such as cherries or plums, one or two long pieces of blunt wood are used to reach the bottom of the bottles, and to press the fruit into position. No space is thus wasted, and the effect is an evenly packed jar. After filling the bottles, pour in clean cold water to overflowing point, put on the rubber ring and the glass lid, and then screw on the metal top loosely. After this stand the bottles on the false bottom in the steriliser, fill this with cold water until the bottles are almost submerged, put on the lid, and gradually heat till a temperature of 160° F. has been reached, which should be maintained for five minutes. Gradual heating is essential, and nearly two hours may well be taken to reach the maximum. After sterilising, remove the bottles one at a time, screwing up the tops immediately, and leave the bottles to cool. It is well to point out that hot bottles should be handled with a dry cloth, and never stood on cold metal surfaces or in draughts, otherwise they may crack.

Temperatures for Sterilising.— The following list gives the heats to which the various fruits should be sterilised. In the case of tomatoes the temperature should be maintained for fifteen minutes.

Apples	180° F.
Apricots	160° F.
Blackberries	160° F.
Black Currants	170° F.
Cherries	160° F.
Damsons	160° F.
Gooseberries	160° F.
Greengages	160° F.
Nectarines	160° F.
Peaches	160° F.
Pears	180° F.
Plums	160° F.
Raspberries	160° F.
Red Currants	160° F.
Rhubarb	160° F.
Strawberries	160° F.
Tomatoes	180° F.
White Currants	160° F.

After Management.—When the fruit has been bottled it is necessary to take care of it, and not merely to put it away on some shelf in the attic and never look at it from month to month. It is important to test the seals of the bottles to find out whether any air is being admitted. This is done by unscrewing the metal cap or by the removal of the clip, and if one can hold up the bottle by its glass lid, it is then firmly and tightly sealed, and the fruit will keep indefinitely. If not, further sterilising is advisable.

As regards the actual storage of the bottles, the best place is a dry room, away from any light, since the fruit then keeps its colour.

The opening of vacuum bottles is a problem which is sometimes difficult to solve. It may be done by forcing the glass lid up, but frequently the rubber band gets damaged in the process. A much better way is to place the bottle in a pan of tepid water and raise the temperature until it nearly boils, when the lid, if touched, will be found to be quite loose.

Bottling in Syrup.—This is undoubtedly the better way of working, since the fruit keeps its colour much better. The strength of the syrup to be used varies, the usual receipt being one pound of sugar to one pint of water. But now very good thin syrups are made by using only two to four ounces of sugar to the pint.

To make the syrup, boil the sugar and water for five minutes, stirring meanwhile, and then allow it to cool. Prepare the fruits in the usual way, packing them tightly into the bottles, and filling to overflowing with syrup. Then put on the lids, and sterilise slowly up to a temperature of 165° F., allowing as usual 1½ hours for the process. Fruit so bottled needs no more sugar, and, of course, requires little or no more cooking.

Bottling in Own Juice.—Raspberries and strawberries are very juicy fruits, and in bottling them the addition of water is liable to spoil their flavour. An excellent way, however, is to pick the berries, sprinkle them with castor sugar (or not), and pack them into bottles without adding any water at all. Put on the lids, screwing them loosely, and place them in a pan with cold water up to the necks of the bottles. As usual, heat the pan slowly to the temperature of 160° F., and by that time the fruit will have shrunk down considerably, and be covered with its own juice. Take out several bottles and fill up one from another, afterwards replacing the full bottles in the pan and re-heat for another ten minutes to 160° F. Screw the top down very tightly immediately each bottle is taken from the pan. In this way the full flavour of the fruit is retained. Blackberries, currants, and loganberries may also be bottled in this way.

Using Ordinary Jars.—If a supply of common glass jars is available, special vacuum bottles need not be purchased. To use these, scald in the ordinary way, fill them with fruit, and sterilise, afterwards sealing them with mutton fat, bladder, olive oil, or layers of paper.

The first method is easy. Have ready some of the melted fat, and cut a small piece of paper large enough to fit inside the neck of each jar; then as each jar is ready to be sealed up, dip the paper into the melted fat, and place it inside the neck of the bottle, pouring in immediately sufficient fat to form a layer half an inch deep. If not air-tight after the fat has set, pour a little more fat on, and tie down with paper before storing away.

Regarding the olive oil, heat some oil, and as each bottle is ready, pour on about three-quarters of an inch and tie with paper.

Bladder is one of the very best seals. The material is cut to the required size, soaked in tepid water, wiped dry, and as soon as each jar is ready, the bladder is stretched tightly across the neck and tied down with string.

Personally the writer has found layers of papers an excellent seal for hard fruits, but as they do not prove an efficient seal for amateur bottling, the method is not described here.

Preparation of Fruit. — Just a word before closing about preparing the fruit for bottling. Taking apples and pears first, these must be quickly peeled with a steel knife, halved or quartered, and packed tightly into bottles, previous to sterilising. To prevent the flesh turning brown, expose them to the fumes of burning sulphur for a couple of minutes in a covered jar.

Bilberries and cranberries may be prepared as for strawberries.

Blackberries and apples, if bottled together, make a delicious mixture. Wash the former, and cut the latter into thin slices, after peeling and coring. Fill the bottles with alternate layers, finally filling with cold water, and sterilise to 180° F.

Cooking cherries bottle readily. It is unnecessary to stone them, but all stalks should be removed after washing, and the fruit packed into bottles and sterilised as directed.

Damsons may be prepared as for plums.

Gooseberries should be bottled young. Top and tail them, and wash thoroughly. Pack tightly into bottles prior to sterilising.

Greengages may be bottled as described under plums.

Plums may be packed tightly or cut in halves, and each should be pricked with a needle to keep the skin from bursting badly.

Raspberries may be prepared in the way mentioned in the section on bottling fruit in own juice.

Rhubarb bottles very well, and ripe sticks should be thoroughly cleaned and cut into even lengths, to fit the bottle. Pack these very closely, afterwards proceeding in the usual way.

Strawberries should be gathered dry, and sprinkled with sugar prior to packing into bottles, as described in the section on bottling in own juice.

Tomatoes may be packed in several ways, according to the size and as to how they are to be used. Plunge the fruit into boiling water for a minute, in order to make skinning easy. Pack into jars either whole or halved, fill in the bottles with brine, allowing one teaspoonful of salt to one pint of water, and sterilise in the usual way. They may also be bottled without water, as recommended for raspberries and strawberries.—E. C.

FRUIT CANNING. — See *CANNING FRUIT.*

FRUIT CULTURE: ESPALIER MODE OF.—See *ESPALIER MODE OF FRUIT CULTURE.*

FRUIT CULTURE, HARDY: General Considerations. — Those who intend planting hardy fruit trees from November to March, should during the fruiting season, look over their gardens and note where improvements can be made to lengthen their supply, by adding early or late sorts; there are generally too many mid-season fruits; and these, as well as useless or old worn-out trees, should be marked for destruction. Notes of desirable varieties should be prepared, taking the lists given at the end of each

article as a guide. Orders should be sent in early to the nurserymen, who execute them, as far as possible, in rotation. Late customers may find certain varieties sold out, and thus a season might be lost.

Planting.—Fruit trees can, as already mentioned, be set at any period within the months named, if the weather is suitable and the land in good friable working condition. It is not desirable to purchase trees at auction sales, as they may prove second-rate varieties left over when all good trees are sold.

If possible, purchasers should visit the nurseries and see the trees in fruit with the various forms of growth and training, and give in their orders. Many growers have fruit rooms, where large collections can be seen, while doubtful varieties could be named for visitors, and advice be given to buyers on the spot.

If by delay in transit the roots are dry and shrivelled when unpacked, immerse them in water for twelve hours. Then taking the tree in the left hand, just above the collar, remove with a sharp knife all those downward thick anchor roots that can be spared, in order to prevent the roots striking too deeply into the lower soil. If the side-roots are few, shorten the anchor roots to one-third, and slightly tip the other roots, always cutting from the lower side. The tree is then ready for planting.

In heavy soils trees may be set almost on the surface, but in light land they should be set in "sunk" holes, which are simply holes made deeper than usual and not completely filled in. [Hints on the actual process of planting will be found in our general article on *PLANTING*. —EDITOR.] As a rule the trees should not be set deeper than they were originally in the nursery. The upper roots should be about 3 ins. from the surface, and the lower ones not more than 18 ins. It is important that Apples on the Paradise stock and Pears on the Quince stock should be so planted that the graft junction is 2 ins. below the surface. Should the early summer be dry, give each tree a pail of water frequently. The roots of trees which are waiting to be planted should, of course, be covered up to prevent the sun and wind getting at them.

Manure.—Ordinary garden soil is quite rich enough for all new trees; but where an old tree has been removed, the soil may be worn out, and here some old decayed manure will be useful in a limited quantity; but some good fresh top spit loam is even better, as it is not advisable for the trees to make a lot of coarse growth, since that prevents fruit spurs forming, and means later on the expense and trouble of root pruning, as well as a year's check to fertility.

Pruning.—In March newly-planted trees, such as Pears on the Quince stock and Apples on Paradise stock, may be carefully pruned down. Bushes and Pyramids should have their branches and leaders shortened to six or eight eyes of the previous year's wood, taking care to keep an even balance of branches on all sides. With Espaliers, if it is desired to increase the height of the side branches (tiers), the leading central shoot is cut back 18 ins. above the top tier of branches; from this cutting three to five shoots may arise, when three should be selected to form the next tier, tying them out laterally when 18 ins. long, and leaving the central upright shoot free. When the desired height is reached, then this central shoot can be cut out. Where Espaliers are planted to form a screen to the vegetable garden, four tiers are ample, but

where they are used to screen the back garden from the lawn, five or six tiers may be allowed.

Cordons will not need any pruning in March, as they are formed in the nursery, and the leader will set fruit buds in the summer. Tall standards being on free stocks—Apples, Pears, and Cherries—should have a year's growth without any pruning; but Damsons and Plums being wig-rooted, take to new soil freely, and can be pruned back to six eyes in March. For further notes on Cordons and Espaliers reference should be made to our articles on *Cordon Fruit Trees* and *Espalier Mode of Fruit Culture*.

Where there are Plums as fan trees, the shoots may be pruned back to eight eyes in March, when the roots are settled and active; but trained Pears are best not pruned for a year. Where Apples are on fences as Espaliers, do not prune them the first year, neither prune Cherries on walls the first year. Wall trees are further referred to in our article on *Garden Walls*.

Stocks Used.—Orchard Apple standards are worked on the Crab or free Apple stock (quite immaterial which). Standard and Espalier Pears are worked on Pear stock. Garden Pears are best upon the Quince stock, which induces early fertility. In the same way Apples on the Paradise Apple stock are best for gardens, as Bushes or Pyramids, as they soon commence to fruit.

The *Paradise* is noted for its fibrous surface rooting habit, which makes the roots respond both to the sun, warmth, and also to the rains, as well as to suitable summer surface mulching, watering or feeding, which should only be given to those trees that bear a full crop. The very best Apple stock, after years of trial in the writer's nurseries, is proved to be the true *Rivers' Broad-leaved Paradise*. He uses no other.

In small gardens tall standard forms of trees are out of place; but if they are desired they should be varieties that do not make much shade, such as *The Czar* and *Victoria Plums*, *Bradley's King Damson*, and *Morello Cherries*.

A pretty archway can be made by planting Cordons on each side of the path, and tying them over in arch form when they are long enough. They are beautiful objects in blossom; especially the Apples, and the fruit is again interesting to watch in development. Where Espaliers are planted they should be placed 2 ft. back from the paths, thus leaving a border for strawberries, parsley, or small vegetables such as radishes and lettuce, or even flowers. Cordons to be trained obliquely should also be set back 2 ft. from the paths.

Aspects for Wall Trees.—When facing south, Peaches and Nectarines, also late Pears, are suitable wall trees. The culture of the two former is dealt with in our article on *Nectarines and Peaches: Outdoor Culture*, and that of the latter is briefly outlined in our article on *Pear: Culture of*. The north is fit for stewing Pears and late Plums, such as *Jefferson* and *Belle de Louvain*; filling in between trees with trained Currants and Gooseberries for late supply, and Morello Cherries. Walls facing west suit Apricots, *Comice*, and *Olivier des Serres* Pears, also Plums and Greengages. When the two latter are planted, they frequently make very strong growths, which if left would become fruitless. It is, therefore, a good plan after two or three years' growth, to lift them bodily in October, cut away down-

ward roots, shorten side roots, and re-plant very firmly in the same position. No fresh soil or manure should be given, but if May is dry, water freely. They will then form fruit buds in abundance.

Walls and fences facing east take Pears and early Plums, such as *Dennistons, The Czar,* and *Oullins Gage.* Room should be found for a cordon or two of Apples, such as *Peasgood's Nonsuch,* to grow a few exhibition examples. Until the Wall trees meet, Cordons in pairs can be planted between each wall tree.

In the Northern Counties and Scotland many Apples are grown on walls. In this way *Cox's Orange Pippin* gives quite good fruit. Late keeping varieties do not complete full growth; they shrivel and become useless if not grown on walls. Apricots, early Peaches, and Nectarines often give quite good results in the north, on south walls.

Planting Distances. — Orchard Standards of the smaller compact growing kinds including such Apples as *Mr Gladstone, Worcester Pearmain*; Plums such as *The Czar, Prolific,* and *Victoria*; Pears such as *Louise Bonne of Jersey*; Cherries such as *Mayduke* and the *Morello,* can be planted 15 ft. apart. Plant stronger growers at 24–30 ft., Sweet Cherries at 36 ft., upright Cordons at 2 ft., Espaliers 15 ft., Wall Trees 15 ft., and Bush or Pyramid Trees about 10–12 ft. apart if possible. In small gardens they can be started at 6 ft.; and when they touch, every other tree can be taken out. In this way perhaps five or six years' crop can be gathered before they meet.

Low Cordons as edgings to paths are not advised, since they are seldom satisfactory, and do not pay for trouble in pruning. Two-branched (*pitchfork*) trees should have 2 ft. of space between each side branch, and three-branched (*gridiron*) trees the same. Apples and Pears are grown in this form, thus giving a great variety in a small space and adding to the interest of the garden.

All trees should be labelled with durable labels at planting time. The labels, which may be of zinc or wood, should be attached by wire to a stake, and not to the tree itself.

General Concluding Remarks.— There are several small details which may conveniently be summed up together here:—

PRICES OF FRUIT TREES.—These can be found in the nurserymen's lists. In consequence of the doubling of wages and extra cost of all materials, prices prior to 1914 are cancelled, and a fair advance is made from year to year.

POLLINATION.—In market culture this has to be carefully attended to by interplanting approved varieties for cross fertilisation; but in gardens where numerous varieties are grown, it need not trouble growers, as Nature will do the work.

SOIL CULTIVATION. — Digging among fruit trees and bush fruits should always be done with a fork; spades cut and injure the roots too much. At all times weeds and grass must be kept down by hoeing. This also acts beneficially in keeping a layer of loose soil on the surface, thus preventing rapid evaporation of moisture in hot weather. Soil stirring with either the hoe or the cultivator also lets in air and sun to warm the roots, and so helps to perfect the crops.

THINNING FRUIT.—Care should be taken to leave each fruit in its best position. Not more than two should be left together, and only one on each spur point if the tree is carrying a general crop. One to each 10 ins. of shoot is a good distance, though to some it may sound extravagant. Remove all imperfect

fruits, and those which are shaded by foliage in the centre of the tree. In the case of early Apples, the removal of fruit for use at various stages saves thinning.

TOP-DRESSING AND MULCHING.—If a tree sets a full crop, a dressing of liquid manure in May will do much good. The soil can then be covered with long strawy dung, and much valuable moisture will be conserved. Good winter dressings in alternate years are kainit, lime, soot, and basic slag, leaving the rain to wash them in.

TROUBLES AND DISEASES.—These are dealt with in other parts of this work under *INSECT PESTS* and *DISEASES OF PLANTS*. A special article will be found dealing with *APPLE DISEASES*. It is well to point out here that insect pests must be attended to immediately they appear, and diseases must be for ever watched for, since otherwise great damage may be done.

Varieties of Fruits.—With thousands of varieties to select from, this is a very difficult task, having regard to the climate of various parts of the United Kingdom. The trade catalogues confuse the novice, but the present writer brings sixty-five years of active work among fruit to bear on the question, and every planter can rest assured that the named sorts which appear in each separate article on the chief fruits are of the very best. If some old favourites are wanting, it may be concluded that they are bettered by more recent varieties.—G. B.

FRUIT: Grading and Packing.

Up-to-date grading and packing ensures successful marketing, and on the latter depends the profit or loss of the fruit farm. It is useless to grow high-class fruit and then market it in a bruised and unattractive condition, as the price it obtains will then be nearly as low as the poorest samples on the market.

As a general rule, insufficient attention is paid to grading and packing in this country, with the result that imported fruit finds a readier market and fetches higher prices than home-grown produce.

Care in gathering and storing is an essential preliminary to good packing, and provided these operations have been carried out properly, the actual grading and packing is a simple matter acquired with a little practice. For gathering and storing reference should be made to our article on this matter.

Grading.—Grading as applied to fruit does not end in sorting the crop according to variations in size, but includes the following points, which are of much greater importance :—

(1) Freedom from injury or blemish.

(2) Good colour.

(3) Ripeness and high quality.

For example, moderate-sized, well-coloured, ripe fruits of good quality, if free from blemish, are properly of first or fancy grade, and are of infinitely more value than very large fruit of indifferent colour and quality.

APPLES.—Large fruit does not keep so well as the smaller ones, and the crop should therefore be graded at picking into at least three sizes, *i.e.* 3 ins. in diameter and over, $2\frac{1}{4}$–3 ins. in diameter, and under $2\frac{1}{4}$ ins. in diameter. At the same

time all bruised or diseased specimens must be sorted out.

The operation can be carried out either by means of a grading machine, if large quantities have to be dealt with, or by hand for small quantities. In the latter case, the fruit are carefully emptied on to a special grading table, and the various grades are then placed in storing boxes or else packed for market.

Wire or wooden gauges of various sizes are sometimes used for grading, but these become unnecessary with a little practice.

PEARS.—The foregoing remarks are in the main applicable to these fruits also, but the choice varieties are much more easily bruised than apples, and therefore not only require more careful handling while gathering, grading, and packing, but must also be carefully watched for ripeness, since when once ripe they rapidly become overripe.

STONE AND SOFT FRUITS.—Grading may be practised also with advantage in the case of these, the finest specimens in all cases being sold in small packages, while the remainder are disposed of in bulk.

The price obtained, as the result of careful grading, nearly always pays handsomely for the extra labour and expense involved.

Packing.—Care in grading must be followed by care in packing if the fruit is to reach its destination with its market value unimpaired, and close adherence to the following points is essential :—

(1) Pack each grade in a separate package. No blemished fruit to be included in the first or fancy grade.

(2) Pack firmly; this prevents bruising during transit.

(3) Pack the choicest fruit in shallow packages wrapped in paper.

(4) Pack honestly as regards weight and quality. Never "top"[1] a package.

(5) Pack while the fruit is still firm and not overripe.

(6) Pack each fruit of fancy grade separately and in layers, if time permits.

Marketing Hints. — Much fruit grown in this country is marketed either in round returnable baskets, holding as the case may be a bushel, half-bushel, or peck, or else in oblong returnable hampers, called "pots" or "half-pots." These empties are usually supplied by the market salesman at a small charge for hire.

It is difficult to prevent apples and pears packed in these baskets from bruising, even though they are packed in layers. In any case the baskets should be lined with packing paper, and if available it is well worth the extra expense to line the sides with corrugated paper. A layer of woodwool or hay is placed both at the top and bottom of the fruit, the top layer being kept in place by packing sticks of hazel or some other easily bent wood. These packing sticks are placed across the top, and rammed in under the rim of the basket. Stone fruit and soft fruit are also packed in these empties, without the woodwool or hay but with the paper lining.

Cooking apples, especially for the northern British markets, are very usually forwarded in grape or sulphur barrels containing 56 or 84 lb.

Rectangular baskets known as "flats," fitted with lids, are some-

[1] A package is said to be "topped" when the bulk of the fruit in it is of indifferent quality, and the top layers are of better quality in order to give the purchaser a false impression of the value of the sample.

times used for high grade apples and pears, but the choicest samples of all should be packed in light wooden boxes known as "trays," holding one or two layers of fruit, each of which is completely surrounded with woodwool.

The practice of marketing carefully graded samples of apples and pears in non-returnable wooden boxes is becoming more and more general amongst those growers noted for high-class produce. There is much to be said in favour of a package of this description, as it opens up a class of trade formerly only catered for by imported fruit.

Soft Fruits.—Soft fruits for dessert purposes, and specially selected samples of stone fruits, are usually marketed in chip baskets or punnets, the former holding 4, 6, or 12 lb., and the latter ½ or 1 lb. of fruit respectively, although pecks, strikes, and half-bushels or sieves are also used. The punnets are used mainly for choice and very early fruit, and are sent to market in crates, each of which holds 32 or 48. Chip

Table of Fruit Marketing Packages

Bonnet . .	Veneer—N.R.	Stone and Soft Fruit	24 lb.	Round.
		Apples	20 lb. (approx.)	Round.
Bushel or Sieve	Wicker—R.	Apples and Pears	40 lb. (approx.)	Round.
Chip Basket .	Veneer—N.R.	Soft Fruit	4, 6, 12 lb.	Oblong.
Flat . . .	Wicker—R.	Apples and Pears	40 lb.	Rectangular.
Half-Bushel or Half-Sieve	Wicker—R.	Stone and Soft Fruit	24 lb.	Round.
		Apples and Pears	20 lb. (approx.)	Round.
Half-Pot . .	Wicker—N.R.	Stone and Soft Fruit	36 lb.	Rectangular.
		Apples and Pears	28 lb. (approx.)	Rectangular.
Peck . . .	Wicker—R.	Stone and Soft Fruit	12 lb.	Round.
Pot . . .	Wicker—R.	Stone Fruit	72 lb.	Rectangular.
		Apples and Pears	56 lb. (approx.)	Rectangular.
Punnet . .	Veneer—N.R.	Soft Fruit	1 lb. or ½ lb.	Rectangular or Round.
Standard Apple Box	Wood—N.R.	Apples and Pears	40 lb. (approx. cu. capacity)	Rectangular.
Standard Apple Half-Box	Wood—N.R.	Apples and Pears	20 lb. (approx. cu. capacity)	Rectangular.
Strike . .	Wicker—R.	Soft Fruit	12 lb.	Round.

baskets and punnets should be lined with white or blue packing paper, and the former should be covered either with paper or else cardboard lids. Dessert fruit forwarded in any of these packages should always be picked with the stalks; but jam fruit, which is marketed in tubs holding 28 or 56 lb., is picked and marketed without stalks, *i.e.* "plugged." Gooseberries and apples for jam are usually forwarded in 1 cwt. bags.

The preceding table indicates the chief packages used for fruit, the materials of which they are made, the kind of fruit for which they are used, the approximate weight of fruit they contain, and their shape. The letter R. denotes that they are returnable, and are used for several journeys, while the letters N.R. signify that they are non-returnable, and therefore used once only.

R. W.

FRUIT PESTS.—See *INSECT PESTS* and *ORCHARD: MAKING AND MANAGEMENT OF.*

FRUIT ROOMS AND FRUIT HOUSES.—When hard fruits are duly gathered in, the question of storage arises, and this is more important than many think. First let me describe "how not to do it," and then give a rational and practical procedure. One very elaborate and handsome structure I know is about 30 ft. square, built of concrete with an inner wall, leaving a 2-foot passage all round; thatched and perfectly finished in all ways. The centre has a bench with drawers below, on which show fruits are set out. There is a 3-foot walk round it. The sides to the ceiling have shelves at 3 ft. apart, set with bevelled slats, so that each fruit has a bed to itself. The slats sand-papered and finished, the floor tiled; here fruit keeps well; but the cost, £300, is altogether out of proportion to its value, as it is empty for some six months, whereas a more efficient house as described directly can be erected for £80.

In another case the room was quite correctly built, but the floor was paved with encaustic tiles, so that the place was too dry and the fruit shrivelled.

In a third case the room was placed against a brick wall, and you entered by two steps below the level; not easy for working! It was damp, clammy, and wanted proper ventilation; consequently, although the fruit kept, it lost flavour and quality. It is not at all needful or desirable to go below the surface.

An Ideal House.—Let me now describe the "Ideal Fruit House" as erected in my Allington Nurseries, where in the height of the season we can store 300 bushels of fruit, and examples of as many varieties of Apples and Pears. It is built on the flat, the corner and chief uprights being set on stone blocks (or concrete), secured by iron dowels let into the wood and stone to prevent slipping. It is then built in the usual way with quartering and stays, the roof being at an angle of forty-five degrees; at the gable apex of the roof, at each end, a hit-and-miss shutter is fixed upright, governed by a cord and pulley, to close the house in cold winds and frost. Outside this a sheet of perforated zinc is fixed to keep out wasps, etc., a 4-foot roll of 1-inch mesh wire netting is fixed to the framework, 1 ft. being sunk into the earth—this is to prevent the entrance of rats or pilferers. There are two windows on each side under the eaves, closed with shutters to exclude the light, and beneath these, 1 ft. from the level, sliding shutters are made to get air below the fruit; these are specially valuable at

gathering time to disperse the sweat which the fruit gives off when first laid in. The entire area of the house and roof are then covered by ¾-inch matchboard outside, and the place is then ready for thatching; if Reed (*Carex*) can be secured it is the most lasting—next stout wheat straw. A thin board is fixed for it to stand on 6 ins. wide, with 4-inch upright boards at the corners, over and round the doors and windows forming a bay to lay the straw in upright, about 4 ins. thick; it is then kept in position by long boards 6 ins. wide laid laterally, and a little taste in placing these gives the house a finished appearance when painted green. In thatching the roof the covering should be at least 18 ins. thick and overhang at the sides, sufficiently wide enough to throw the drip well away from the side walls. Both the roof and sides should be very firmly thatched. If heather is used on the roof, the pitch should be at an angle of fifty degrees. The doors at each end should be double, the stout outside one opening outwards and the inner lighter door inwards. The doors are not panelled.

We now come to the inside arrangements. Shelves should be 2 ft. wide round the outside. Start by placing uprights 2 × 2 ins. from the ground, fastened to the rafters at about 6 ft. apart, then arrange bearers 2 × 1½ ins. to the wall; upon these lay matchboard longways, leaving half an inch between each board. These side shelves start 1 ft. from the ground at 18 ins. apart. On each place a slight cover of clean wheat straw 2 ft. long, shortways; this prevents fruit touching the wood and being flavoured by turpentine; it will last for years. The shelves are not run across the side windows.

A central table is then made about 6 ft. wide: the uprights must be 3 × 2 ins., fastened to the rafters, and the bearers 3 × 2 ins. from side to side; the lower shelf 1 ft. from the ground, and the main central table 3–4 ft. from the ground. This, which runs the entire length, is of matchboard, with ½-inch opening between each board. On this heaps of the smaller dessert fruits can be placed, and it adds interest to the place if at the entry end a named collection of the finest examples are placed so that visitors can readily inspect the fruits. This is a pleasing feature now that nearly all employers take a personal interest in fruits and their names. Above this central table another floor is made with outside upright edge boards 3 ins. wide. Here apples can be laid in bulk, provision having been made to strengthen it by extra uprights in the centre of the table. The space below the show table is used to store baskets of odd sorts in a full year. For laying up fruits see a separate article on *Gathering and Storing Fruit*. The secret of success lies in keeping the natural earth floor always damp — not muddy. Always remove fruits that may decay at once. Store pears on the cool side of the house. Place the latest-keeping apples on the lower shelves. Our own house is about 60 ft. long by 16 ft. inside, and was erected by our men at a cost of £80.—G. B.

FRUIT TREES: Spraying.

Fruit trees and bushes have a great many enemies in the shape of insect pests and fungoid diseases, and the gardener who wishes to keep his trees healthy and produce clean fruit must be prepared to deal promptly with these troubles. In most cases the only possible treatment is to spray with a suitable insecticide or fungicide. Recent years have seen great development of the science and practice of spraying. The life-histories of the various pests and diseases have been studied, and many spraying-fluids introduced as remedies and preventives. The gardener may not look with favour upon spraying, but he has come to regard it as a necessary evil. Indeed, the up-to-date grower now considers it as part of the ordinary routine of fruit culture.

Winter Spraying. — The year's campaign may be said to start with winter spraying. The chief object of this is to rid the trees of mossy growth, lichen, and loose bark, which not only impede the healthy functions of the bark, but also serve to harbour hibernating insects and their eggs. This spraying is not required every winter. The time taken for the trees to become green with mossy growth varies with the district, but in most places it is desirable to spray every two or three years. Summer spraying does not remove these growths, because washes strong enough to do so would destroy the foliage, and can only be used whilst the trees are dormant.

There are many proprietary winter washes on the market, and most of these can be relied upon. A simple home-made wash is prepared by dissolving 2½ lb. caustic soda (98 per cent. purity) in 10 gals. of water. This solution will burn the skin, so gloves should be worn, and care taken not to let the spray blow on the face. Plain limewash is also excellent. To make this, 20 lb. of the best quality freshly-burnt quicklime in lumps is slaked in a tub by just covering the lumps with water. When slaked, more water is added very gradually, stirring to a smooth cream, which is finally diluted to make 10 gals. of wash. It must be passed through a fine wire sieve or piece of sacking, and coarse nozzles used on the spraying machine or syringe.

Winter spraying can be done at any time whilst the trees are dormant, but is usually left till February, by which time insect pests are showing signs of life and are more vulnerable. The only exception is plain limewash, which is often used much later, just before the bloom buds open, in the hope of killing the aphides (greenfly) which are then hatching, or of sealing up their eggs so that they fail to hatch.

Spring and Summer Spraying.— Round about blooming-time the grower should have his trees under constant observation, for it is then that numerous enemies make their appearance, and prompt action is more than half the battle. As soon as the first tender leaves expand, aphides, apple suckers, and various caterpillars are likely to be found. We cannot spray whilst the bloom is fully open, but we can whilst it is in bud form, and again as soon as the petals have fallen. The enemies to be dealt with at this time may be roughly classified as follows :—

(1) Leaf-biting insects, such as various caterpillars.

(2) Pests which live by sucking the plant's juices, such as the different aphides or greenfly.

(3) Fungoid diseases, such as apple and pear scab, brown rot, etc.

The first class, the caterpillars, are easily killed by poisoning their food. This is done with great certainty by spraying with arsenate of lead, bought in the form of paste, and dissolved in water at the rate of 1 lb. to 25 gallons.

The second class, the greenfly, etc., are more difficult to kill. Poisoning the surface of the leaves is of no use, as they pierce to the inner tissues of the plant to obtain the juices on which they live. We must therefore use washes which act directly on the insects. The best is nicotine (95 per cent. purity), 1½ oz. to 10 gals. of water; but it is expensive. A cheaper wash may be made from 1 lb. quassia chips, 1 lb. soft soap, and 10 gals. of water. Boil the quassia with half the soap in some water for an hour, then with the rest of the soap in fresh water for another hour. Mix the two solutions, and make up to 10 gals. with water. Whatever wash is used, the great thing is to spray promptly, as, once the pests get a firm hold, particularly when curled in the leaves, spraying is almost useless. It must be repeated as required.

When both caterpillars and aphides are present at the same time, arsenate of lead may be dissolved in either of the washes just mentioned, or in any other aphis wash, using 1 lb. of the arsenate paste to 25 gals. of the diluted wash. It should not be mixed with the wash whilst in concentrated form.

There are, of course, numerous proprietary insecticides on the market, some for greenfly alone, others for caterpillars as well; and many of these do excellent work.

We now come to the third class of enemies, the fungoid diseases, such as scab and brown rot. We must *not* wait for these to appear, as treatment, to be really effective, must be preventive rather than remedial. The state of the leaves and fruit in the previous year should be the guide. If they were diseased, the affected trees should be sprayed with a fungicide three times: (1) When the bloom buds show white, but before they open; (2) as soon as the petals have fallen; (3) about three weeks later.

The most commonly used fungicide is Bordeaux Mixture, which is best bought in the form of a paste and diluted according to the maker's directions. Lime sulphur wash is probably superseding Bordeaux, being less liable to scorch the foliage. Several makers offer it in concentrated liquid form. Directions are given by the makers for diluting for "winter strength" and "summer strength," for, used strong, this is an excellent winter wash.

Hints on Spraying.—Calm, fine weather should be chosen for spraying, and care taken to reach every part of the trees. Spraying machines of many types are on sale. A knapsack sprayer is convenient for the average orchard, but in a small garden the work can be done with a good syringe, provided that it be fitted with a proper spraying-nozzle, and not the usual perforated rose of the common garden syringe.

When spraying for insects, especially aphides, a fairly coarse nozzle may be used, and the trees thoroughly and forcibly wetted. When using a fungicide, however, it is most important to apply it as a very fine mist-like spray, and never to play on the trees till the wash drips off the points of the leaves, or there is likely to be scorching.—E. M. B.

See also *SPRAYING MIXTURES AND FUNGICIDES*.

FRUIT: Weight of Bushel of.—See *WEIGHTS AND MEASURES*.

FUCHSIA (Nat. Ord. Onagraceæ).

Florists' section, half-hardy shrubs, 2–3 ft. high, succeeding in a soil of good turfy loam 2 parts, and 1 part each of old manure and leaf-mould, with a sprinkling of old mortar rubble. They are propagated by seed and by cuttings, the latter being the usual method.

Culture.—Old plants that have rested over the winter, placed in a warm house in February, will soon make new growth. When the young shoots are about 2 ins. long, they can be taken off and placed in pans or pots of sandy soil, where they will form roots in a few weeks if a temperature of say 60° F. is maintained. By April they will be ready for shifting into 3- or 3½-inch pots, and at this stage should be kept near the glass to encourage sturdy growth. If intended for summer bedding, the plants will be nicely established for planting out by the end of May. Those meant for conservatory decoration should be re-potted into 6-in. pots, or even those of larger size if specimen plants are required. The leading shoot is retained its full length, but judicious pinching of the side-growths will tend to form a shapely and pyramidal bush.

Fuchsias are often used as dot plants for summer bedding, but they reach their greatest perfection grown in pots under glass, some of the species with pendulous growth making admirable subjects for hanging baskets. They all flower over a long period.

Varieties. — *Double.* — Avalanche, Ballet Girl, Duchess of York, Lena, Molesworth, Phenomenal, Sensation, and Sylvia.

Single.—Beauty of Trowbridge, Benita, Gertrude Pearson, Marinka, Mrs Marshall, Mrs Rundle, Swanley Yellow, and Titian.

About 1905 a new batch of seedlings, derived mostly from *Fuchsia triphylla*, came from the Continent. The best of these are Clio, Coralle, Eros, Fürst O. von Wernigerode, Gartenmeister Bonstadt, and Gotingen.—J. L. G.

See also *SHRUBS*.

FUCHSIAS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING*.

FUEL ECONOMY.

Various suggestions have been made from time to time for the economical using up of the smaller portions of our fuel, and we are advised to mix it with peat, clay, lime, or other materials. The best idea appears to be to make a mixture of equal parts cinders, small coal, coal dust, or coke, watering the material generously meanwhile with the strongest brine. The mixture can then be shovelled into the greenhouse furnace as it is, or sugar bags can be filled with it and one of these put in as required. The last idea gives the best results, as the heat of the furnace causes the material to congeal together into a solid mass which will take many hours to burn through. Where pitch is available a tenth part of the solid after being finely crushed can be mixed with the cinders, etc., instead of watering with brine, and will give fairly satisfactory results. In colliery districts old pit props are often available cheaply for use as fuel. The ash from these is, of course, of extreme value for digging-in purposes.

FULHAM OAK (*Quercus Cerris fulhamensis*).—See *TREES*.

FULLER'S TEASEL (*Dipsacus Fullonum*).—See *DIPSACUS*.

FUMANA.—Now included in the genus *HELIANTHEMUM*.

FUMARIA (FUMITORY. Nat. Ord. Papaveraceæ).—Most of the plants known as FUMITORIES are now included in other genera such as *CORYDALIS* and *DICENTRA*, upon

each of which separate articles are devoted. The species retained are hardy annuals and hardy annual climbing plants, merely requiring to be sown where they are to bloom in good garden soil. The best of the first are *F. densiflora*, *F. officinalis* (the COMMON FUMITORY), and *F. spicata*, while *F. capreolata* (Syn. *F. media* of some authorities) is the best climber. All bear pale pink flowers in July, and average 1–4 ft. in height.

FUMIGATING.

The best method of destroying insect pests, such as Black Fly, Green Fly, Red Spider, and Thrips, on fruit trees and plants of all descriptions growing under glass, is by fumigating with smoke fumes. There are various compounds for vaporising which can be bought from any nurseryman ready for use. The old way of fumigating was chiefly with paper and rags soaked in tobacco juice and afterwards dried for use, as ordinary smoking tobacco was rather expensive for such purposes. If the system of using brown paper and rags is to be continued, material of the best quality should be used, as good plants may be injured or killed by the effect of the smoke fumes of bad material. The best quality of tobacco paper can be bought from any nurseryman ready for use.

When to Fumigate. — The best time to fumigate glasshouses or frames is a dull, damp, calm evening, as then the smoke will not escape so quickly. The foliage of the plants must be thoroughly dry at the time, otherwise it is sure to get scorched. The amount of smoke to be used depends on the class of plants that are to be fumigated, and whether the foliage is tender or hardy, and also if the plants are flowering. A gardener must judge for himself from the class of plants that he is going to fumigate as to whether they are tender subjects or not, and use the amount of smoke accordingly. Never fumigate in the morning, for the sun may come out very brightly at any moment, and the plants would be destroyed or very badly scorched on account of being in a house full of smoke fumes.

Fumigators. — To fumigate with the least trouble a proper fumigator should be purchased. These are manufactured in various kinds, and it would obviously be out of place to name any one make here. A satisfactory substitute frequently used by gardeners in large establishments for tobacco paper is a 9-inch flowerpot inverted upside down, a 1-inch sand-riddle being put on the top of the pots, with a shovel of red coal cinders in the centre of the riddle. Then the tobacco paper is put over the cinders, and the whole covered with damp sphagnum moss. It is advisable to see that no flames appear, and to avoid this the moss must be kept damp by the use of a watering-can with a fine rose. The writer always finds it best, after the houses are washed out in spring and plants sponged over, to give the house a slight fumigating occasionally as a preventive to the increase of insects.

Ferneries must be fumigated very slightly, as the majority of ferns are very tender and easily scorched. On the day the house is to be fumigated refrain from damping paths or foliage. Greenhouses with plants in full flower must also be fumigated very lightly, otherwise the blooms will be spoiled, but fumigation may be as frequent as you like. A greenhouse containing but one variety of plants is, of course, much easier to fumigate than a house of mixed plants.

There are, as already mentioned, a great number of fumigators on the

market at present, and they are all very good, though some are easier to use than others. The type with a glass-bottle lamp which burns methylated spirits through a round wick is the most satisfactory. There are also various compounds for vaporising obtainable in different sized bottles. The house to be fumigated will require to be measured in order to estimate the cubic feet of space. (See *ARITHMETIC AND GARDENING.*) This done, you can easily judge the quantity of the vaporising compound required, as directions are usually given on the bottle as to how much is required to fumigate each 1000 cubic feet. If carefully done, it will destroy all pests without doing the slightest injury to the most delicate foliage, flowers, or fruit.

For destroying Red Spider, Thrips, etc., on vine foliage in a large vinery, use sulphur mixed in a can of buttermilk and worked into a fine paste. Take a whitewash brush and, having the hot-water pipes well heated, close all the vinery ventilators and doors, and then paint the pipes all over with the sulphur paste. A dull, damp evening is best to paint the pipes, in order to be certain that the sun will not come out brightly after putting the sulphur on the pipes. The sulphur will not require to be taken off the pipes the following day; it can be left on, and will keep a nice sulphur fume all through the house each time the house is damped or closed.—J. C.

FUNCTIONS OF ROOTS.— See *ROOTS OF PLANTS : THEIR FUNCTIONS.*

FUNGI : Edible and Harmful.

It is to be hoped that, ere long, our acquaintance with the physical properties of Fungi will be analogous to that we now possess in regard to common fruits of the garden and orchard. As stone-fruits, for example, differ considerably in size, shape, colour, taste, and economic value, so our common fungi exhibit variations even more striking in their characteristics. Some are designated as "edible," others as "poisonous"; but these terms are comparative, and do not necessarily divide all fungi into useful and useless types. Just as some well-known fungi are more appetising than others, so are there specimens more intensely poisonous than their harmful relatives. In short, the 2000 fungi found in our woods and meadows grade themselves naturally from the most toothsome and nourishing down to the most repulsive and nauseous.

How can we distinguish the edible from the harmful? Simply by improving our knowledge of the commoner types. So-called "rule-of-thumb" methods are obsolete, useless, and may be disastrous. Formerly it was assumed that a fungus was edible if the skin peeled easily from the cap, and that any poisonous fungus—or "toadstool"—would immediately stain a silver spoon if brought into contact. These old-fashioned ideas have no foundation in fact. Indeed, it is impossible to frame any such rules for guidance in determining the nutrient qualities of fungi.

The safe-and-sound method may be more tedious, but it invariably produces the best results, and seldom brings any casualty in its train. By this method we study the best-known "edible" mushrooms first,

and become thoroughly grounded in their physical aspects, such as size, colour, contour, smell, and special characteristics. Having mastered about thirty types, so as to be able to identify them at any time and anywhere, we may delve into the "harmful" variety, noting their contrasts, lurid colours, evil odours, and any other peculiar features that bar them from table patronage. Thus, from a definite acquaintance with each kind of fungus, we gain that certainty of identification which distinguishes an apple from a pear, or a Blusher from a Grisette.

In the following notes the word "pileus" is used to denote the cap or crown of the fungus supported by the stem. "Cuticle" refers to the outer skin or covering of the pileus. A "volva" is the wrapper, bag, or sheath enclosing certain fungi in their earliest stage; as growth proceeds, the volva is pierced by the cap, and its remnant is left round the base of the stem.

Herewith we give details of the more common types of edible and harmful fungi:—

EDIBLE FUNGI.

Anisette (*Clitocybe fragrans*) is, as its name implies, a fungus of fragrant odour, smelling strongly of anise. The pileus or cap is greyish-white, translucent in wet weather, but opaque when dry. It is convex, spreading to a plane, with margins thin and transparent. The stem is naked, slender, stuffed with pith, and becomes tubular. Anisette is common in fields and on the borders of woods from July to November. It often survives the withering frosts of late autumn, and may be gathered on a mild Christmas Day.

Bleeding Agaric (*Agaricus hæmorhoidarius*) is unmistakable. When crushed it exudes blood-red juice. The brownish cap is tinged with red or purple; gills are bright-red to purple; the flesh of cap and stem is white and solid; when bruised or cut this instantly becomes red. The ring round the stem is prominent and elastic. Bleeding Agaric abounds under pine trees in September and October. As an esculent it is held in high repute.

Blewit (*Tricholoma personatum*) was once very popular, and sold readily with the common Mushroom (*Agaricus campestris*). The cap is pale yellow or tannish, with margins incurved and slightly downy. Gills are crowded and greyish-white; they retain this colour permanently, never changing when cut or bruised. Stem is stout, solid, and tinged with lilac; the flesh, too, when cut, bears trace of the same tint. Blewit is common in grassy woodlands and open spaces.

Blusher (*Amanita rubescens*) is found in summer and autumn under oaks and beeches. It averages 3–6 ins. high, with a cap 2–5 ins. wide. This cap is reddish-brown, spotted with small portions of the volva, and is globose when young, but becomes nearly flat with age. The gills are white or blotched with brown. The stem, too, is whitish; but when bruised or cut the flesh "blushes" to a pale-red tint. This feature is characteristic of the fungus. The ring round the stem is large, flabby, and bears a delicate pink tinge.

Chantarelle (*Cantharellus cibarius*) appears plenteously in beech woods in early autumn. The yellowish-brown caps are discovered in groups among the short grass and mossy undergrowth. The pileus, 2 ins. wide and 1–3 ins. high, is divided into unequal lobes with a smooth, wavy surface. The gills are distinct, not crowded, and pass down the stem, which is funnel-shaped. When

dry, the Chantarelle has the odour of a fresh apricot.

Dainty Bolet (*Boletus edulis*).—Of the many bolets growing in British woods and pastures in late summer, the "Dainty" is most popular. Like all other bolets, the under surface of the pileus is crowded with pores, resembling a pin-cushion well perforated. The cuticle is velvety, of a brownish-buff tint, and the pores become yellowish-green with age. The stem is thick, solid, and smooth, with a fibrous network on the upper portion; it is 2–4 ins. long. The flesh is white, and does not change colour when cut or bruised.

Great Puff-Ball (*Lycoperdon giganteum*) is identified at first sight. As an irregular white ball, 5–9 ins. in diameter, fluted towards the root, it thrives splendidly in autumn in rich meadows or on the borders of woods. At first, the skin is tough and smooth; with age it peels away and becomes watery. The fungus assumes a yellowish tint, the inner part becomes powdery, and the plant is then unfit for food.

Grisette (*Amanitopsis vaginata*) grows luxuriously in the neighbourhood of pine woods in autumn, scattered and in groups. The bell-shaped pileus, with grooved margin, varies in colour from livid white to light brown; it is smooth first, then scaly, and is covered with patches of the volva. This root-sheath is very prominent, sometimes covering one-third of the stem, which extends from 4 to 6 ins., and is attenuated towards the pileus. Gills are persistently white; they do not change to salmon, blue, or other colour.

Helvel (*Helvella crispa*) is quite distinct from other species, with crisp, wavy, white, yellowish, or flesh-coloured cap, which clings to the stem at first, then becomes free. The stem, which is tinted like the cap, is furrowed and hollow, narrowing towards the top.

Horse Mushroom (*Agaricus arvensis*) is often cooked with the common Mushroom as an agreeable mixture with stronger flavour. It ranges from 2 to 6 ins. high, with a pileus from 4 to 9 ins. wide. It is white, or tinged with yellow. The flesh is solid, white, strong-smelling, and does not turn brown when cut. The large white gills change to brownish-purple; the stem bears a loose, broad ring.

Morel (*Morchella esculenta*) enjoys an excellent reputation, and is quite unique in form and structure. In spring and early summer it appears on limy and clay soils in hedgerows and in meadows. The cap is hollow and is divided into a network of polygonal cavities with a velvety spore-shedding surface. The stem is also hollow, slightly fluted, and bulbous at the base. Morel is grey, buff, or tawny, and about 3 ins. high.

Mushroom (Common) (*Agaricus campestris*) has distinct features that are well known. Mistakes occur, and "somewhat similar" fungi are gathered instead. The Mushroom bears a white cap, ball-shaped when young, convex or plane on maturity, with portions of the ring clinging to the margin. Gills are light-pink, then reddish-brown, and ultimately brownish-black, watery, and deliquescent. When cut or bruised the white flesh changes to a dingy brown. The stem has a prominent fringe near the cap. [For cultural details see our article on *Mushrooms*.—Editor.]

Oak-Tongue (*Fistulina hepatica*), also known as Beefsteak Fungus, grows rapidly in autumn on living elms and oaks. It extends, tongue-like, with little or no stem, from the trunk 4–18 ins., with a thickness

of 2–4 ins. It is blood-red, soft, pimpled, flabby when old, and bears on its lower portion a mass of salmon-coloured pores. The taste is slightly acid and vinous.

Red-Milk Fungus (*Lactarius deliciosus*) is one of the most fragrant of esculents, abounding in fir, pine, and larch woods, where its orange-red cap may be seen well distributed. The cap is viscid, strong, and develops greenish zones on the cuticle. When cut, the pale flesh freely exudes saffron-red milk—a distinct feature of this fungus.

Shaggy Caps (*Coprinus comatus*) grows in dense clusters on waste-heaps, roadsides, and hedgerows throughout the summer and autumn. The pileus quits the ringed stem and becomes cylindrical, dingy-brown in colour, with a peeling cuticle that gives it the well-known shaggy appearance. The gills are white, changing to pink and black, eventually melting into an inky fluid. The stem—4–6 ins.—is slender, hollow, and bulbous at the base.

Urchin-of-the-Woods (*Hydnum repandum*), known also as HEDGEHOG FUNGUS, has its sporing surface composed of spines instead of gills or pores. The smooth pileus—2–4 ins.—is reddish-yellow; spines and stem have a paler tint. The spines are crowded, very brittle, conical, and emit a slight acid odour. The flesh is white, solid, and does not change colour when cut. The fungus appears in groups, in grass, and among ferns, preferably in clay soil.

HARMFUL FUNGI.

Arch-Bane (*Amanita phalloides*). —Of all British fungi this is the most deadly in its poisonous effects. Known also as DEATH CAP, it contains toxic *phalline*, which acts rapidly, and generally with fatal results. Unfortunately, it grows among edible mushrooms in open fields and woods, and may be innocently gathered with them. The cap is yellowish-green, viscid when wet, and bears small patches of volva. The gills are white, and remain so; they never turn pink or purple like the edible Mushroom. The stem is white and smooth, with a large ring-frill round its upper part and a thick, yellowish-white volva about the base. The fungus emits an unpleasant odour, especially when fully grown.

Hairy Foot (*Marasmius peronatus*) is very common in fields and meadows during the autumn. Its pale, tan-coloured pileus and thin, naked stem, with base swollen and covered with a crowd of hairy filaments, are easily recognised.

Liberty Cap (*Psilocybe semilanceata*) abounds in open grass-land and hedgerows from spring to the end of autumn. The conical pileus amply illustrates the common name of the fungus. The gills are first brown, and change to purple-black. Stem is slender, naked, and 2–4 ins. long.

Panther Cap (*Amanita pantherina*) is often mistaken for Grisette or Blusher. It differs from Grisette in having a prominent ring-fringe on the stem, and a decidedly bulbous base. In Panther Cap the gills and flesh remain white; they do not "blush" or turn pink when cut or bruised, as is the case with *Amanita rubescens*.

Scarlet Fly-Cap (*Amanita muscaria*) has such a brilliant scarlet cap, sprinkled with white patches of the volva, that it cannot be confounded with any other fungus. It is common in pine and birch woods. The gills and flesh are white; its stem is 4–6 ins., swollen at the base, with a white ring-fringe near the pileus. The fungus is very poisonous.

Sickener (*Russula emetica*) haunts open woods and meadows in late autumn. The cap is bright-red, becoming more lurid, then turning pale after maturity. The cuticle will strip. Gills and flesh are white, brittle, and often snail-eaten. The stem is 2–3 ins., and bears no ring.

Slayer (*Lactarius rufus*) is a common and dangerous fungus growing in most pine and fir woods, and often in small plantations. It is confounded with Red Milk (*L. deliciosus*), being somewhat similar in size and colour. The cap and stem are chestnut-red, the gills being slightly paler. No green zones appear on the pileus. Flesh is pale-buff, and when cut or broken exudes *white* milk—not red.

Sorceress (*Amanita mappa*).—This very poisonous fungus grows in woodlands, fields, and parklands from August to November. The cap is whitish to sulphur-yellow, and is sprinkled with loose warts. Convex at first, it becomes flat on maturity. Gills are clear-white and crowded. Stem, too, is white, and bears a loose ring-frill. The base is bulbous and covered with a loose volva. Odour is unpleasant.

Sulphur Tuft (*Hypholoma fasciculare*) will be recognised in dense clusters about decayed tree-roots and stumps. A cluster may contain hundreds of sulphur-yellow fungi bundled together in mass. Cap, gills, stem, and flesh are all yellow. Spores are purplish-black. The stem is slender, hollow, brittle, puffed at the base, and bears a slight ring. This fungus is dangerous, and emits a repellent odour.

Verdigris Fungus (*Stropharia æruginosa*) appears in damp woods, fields, and pastures during autumn, with a slimy, green pileus sprinkled with greyish-white warts. The green slime washes away, leaving a dirty-yellow tint. Gills are white, then brown, and turn with age to a purple colour. Stem is hollow and smooth above the ring; below the ring it is slimy and covered with scales. In the "button" stage the fungus is bright-green.

Woolly White Lactar (*Lactarius vellerius*) grows luxuriantly in pine and beech woods, singly and in small groups, and sometimes measures 4–9 ins. wide. The pileus is chalky-white, with a woolly cuticle spattered with soil. At first, the cap is convex, then it flattens and becomes funnel-shaped, with the margin curving under. Gills are white, broad, not crowded, and run down the thick, white, naked stem. The flesh is white and solid; when cut or broken it exudes white milk, which acquires a yellow tinge and is certainly harmful.—J. H. C.

FUNGI IMPERFECTI.—A group of fungi. See *FUNGOUS DISEASES*.

FUNGI PARASITES.—These are referred to under *FUNGOUS DISEASES*.

FUNGICIDES.—See *SPRAYING MIXTURES AND FUNGICIDES*.

FUNGOUS DISEASES.

As in the animal world the greater number of diseases are now known to be due to the action of parasites, mainly bacterial, so in the plant world diseases are also very largely of parasitic origin, mainly fungal, though there are a considerable number also of bacterial diseases. In addition there are the so-called physiological diseases, where the physiology of the plant is deranged, but not through the agency of a parasite.

Since fungi are devoid of chlorophyll (the green colouring matter in plants), none of them are able to obtain their organic food-supply from the air as can ordinary green plants. As a consequence they

live either on dead organic matter, when they are called *saprophytes*, or on living organisms (plants or animals), when they are termed *parasites*. By far the larger proportion are saprophytes, which, while living on dead leaves, branches, etc., are at the same time performing the useful service of bringing about the decay of dead vegetable matter. The number of parasites is, however, very considerable, and is increased by those potential parasites which as a rule live saprophytically, but under certain conditions become parasitic and attack living tissues.

Fungous diseases cause great losses year by year to English agriculture and horticulture—the great epidemics that sweep over Canada and the United States are here more often represented by the insidious daily toll that is taken by all the more common diseases. Nevertheless it is no exaggeration to say that several millions of pounds are lost yearly, and that this loss is to a large degree preventable. A vast proportion is represented by the damage done to corn and potatoes.

The fungi can be divided into four groups as follows :—

(1) **Basidiomycetes.** — The distinguishing feature here is that the final spore is borne on a special body termed a *basidium*. The mushroom and all the toadstools belong to this group. Some of the latter are parasitic and attack trees (*e.g.* Beech Root Rot and Silver Leaf of Plum). The timber-destroying fungi, *Polyporus* and *Fomes*, likewise find a place here, and also the notorious Dry Rot fungus (*Merulius lacrymans*), which, however, confines its attack to worked or stored timber. Although not typical members, the Rusts and Smuts may also be assigned to the Basidiomycetes (see *Rust Fungi* and *Smut Fungi*).

(2) **Ascomycetes.**—This division is characterised by the fact that the final spores are borne in a sac or *ascus*. Other spores may be formed at the earlier stages apart from these sacs, and these are usually termed *conidia*. The group is a large one and contains several very destructive diseases, including Apple Canker and several other cankers, the true mildews (apple, rose, gooseberry, etc.), and many others, amongst which Cherry Leaf-Scorch, Peach Leaf-Curl, Sycamore Blotch may be taken as examples. For treatment, reference should be made to our articles on *Apple Diseases*, *Diseases of Plants*, *Rose Diseases*, etc.

(3) **Fungi Imperfecti.** — Another large group, which consists to a considerable extent of imperfect forms of one or other of the above group, and whose exact position therefore is difficult to assign. Many, however, such as most of the moulds, are quite independent. Conidial stages of the Ascomycetes are amongst some of the most general and injurious of parasites, *e.g.*, Apple Scab, Cucumber Blotch, Potato Dry Rot, Rose Blotch, and Tomato Canker. Parasitic moulds are less frequent, but the fact that Cladosporium and the ubiquitous Botrytis are ready, if suitable conditions are only present, to attack almost any plant, may be cited as examples. For treatment of these, reference should be made to the articles above mentioned.

(4) **Phycomycetes or Lower Fungi.** —These are mostly minute fungi of simple organisation, resembling in structure some of the lower algae. Like them they require much moisture, and many have motile swimming spores. Wart Disease of Potatoes, the Downy Mildews (*e.g.* Onion and

Wallflower Mildews), and the notorious Potato Blight, belong to this group.

Predisposing Causes and Treatment.—The conditions determining the intensity of a fungus attack are numerous, and interact with each other. Weather is undoubtedly the most potent, the amount of moisture and degree of temperature being as a rule the decisive factor in favouring or checking an attack by fungi or an epidemic outbreak. Of cultural factors the amount of manure has probably the greatest influence, heavy dressings of nitrogenous substances undoubtedly rendering plants more susceptible. The special methods of control are indicated under each disease dealt with in this volume, many of the less important being included in the article *Diseases of Plants*, whilst others will be found under the names of plants which they attack. With regard to general treatment, if the following rules are attended to, disease would be much less prevalent than it is: (1) avoid overcrowding; (2) never allow diseased and dead material to accumulate, but burn all rubbish at frequent intervals; (3) keep down weeds; (4) do not overmanure; (5) do not neglect to lime (quicklime or chalk); (6) tackle the disease early, as soon as it is seen; and (7) rotate the crops.—A. D. C.

FUNKIA (Plantain Lily, or Plantation Lily. Nat. Ord. Liliaceæ).—The family takes one of its English names from the resemblance of its foliage to that of the common Plantains of our meadows and roadsides. As a rule the flowers are of small decorative value, and it is because of its ornamental leaves that the plant finds a place in our gardens. In several instances these are beautifully variegated. Although one of the Liliaceæ, the root system is more like that of an herbaceous perennial than what is usually associated with the lily tribe.

Culture.—Ordinary good garden soil and a sunny position suit Funkias very well. Propagation by division in March is easy. They may be grown in pots for conservatory or winter-garden decoration. In this case they should be wintered in a cold frame until they are brought into a cool greenhouse. Funkias thrive and do well in town gardens where few other plants will grow.

Species and Varieties.—The best sorts are:—

Funkia lancifolia.—This has pale lilac flowers and green foliage. It blooms in July or August, and grows about 10–12 ins. high. The best sub-varieties are *albo-marginata* with pale green leaves margined white, and *undulata* with waved foliage.

F. ovata.—This has lilac flowers and handsome glaucous foliage. It grows about 1 ft. high. A pleasing variety is *aurea maculata*, with golden or golden-edged leaves.

F. sieboldiana.—This has beautiful bluish-green leaves and bears pale lilac flowers in July. It grows 12–18 ins. high.

F. subcordata (Corfu Lily).—This bears white flowers in August, and grows about 1 ft. high.

J. J. & E. T. E.

FURNITURE FOR GARDENS.—See *Garden Furniture*.

FURZE.—A name applied to the genus Genista. See *Shrubs*.

FURZE.—The genus Ulex. See *Shrubs*.

G

GAGEA.—See *YELLOW STAR OF BETHLEHEM.*

GAILLARDIA (BLANKET FLOWER. Nat. Ord. Compositæ). — The ANNUAL SPECIES of this genus are very bright useful plants, carrying gaily coloured flowers on long stems which make them excellent for cutting. As, however, they dislike over-wet winters, autumn sowing outside is undesirable, though if raised from seed sown in July and August and wintered in a frame, a useful stock for planting out in April is obtained. More often they are raised by sowing in gentle heat in February or March, namely, by treating as half-hardy annuals. The best sorts are briefly described below :—

Gaillardia amblyodon (Syn. *G. scabrosa*).—This bears bright crimson flowers from June to October, and grows 2 ft. high.

G. bicolor. — See *G. pulchella* below.

G. Drummondii.—See *G. pulchella picta* below.

G. picta.—This sort, so often offered, is the variety *picta* of *G. pulchella* below.

G. pulchella (Syn. *G. bicolor*).—This species bears immense yellow flowers from June to October, and grows 2½ ft. high. Many varieties of it are now on the market. The best are : *Coccinea* (deep crimson and gold) ; *lorenziana* (double, red and yellow) ; and *picta* (Syns. *G. Drummondii* and *G. picta*), which has crimson and golden-yellow flowers. *The Bride* is a charming white hybrid.

Perennial Border Species.—These include some of the most attractive of all hardy perennials, exceedingly useful for the perennial border and for cutting as they are of exceptional beauty. There are a good number of lovely hybrids offered by the trade, and striking new sorts of even greater beauty are sure to follow. The perennial species succeed best in a warm sunny site protected from cold winds, and in exposed northern districts where snow and sharp frosts are abundant, it is well to lift and winter them in a light frame. They may be successfully raised from seed sown in the usual way for hardy perennials in the summer, and propagation by division of the roots in October or November is not a matter of much difficulty. The best time to plant them is in early March. The following is a selection of the best species and hybrids :—

Gaillardia aristata.—This popular species bears orange flowers in July and August, and grows about 2 ft. high.

G. hybrida.—The sort named thus by nurserymen bears flowers of various yellow shades from June to September, and grows about 2 ft. high. It is probably a seedling variety of *G. aristata.* Some of the best of the numerous named sorts classed as hybrids but probably further seedlings of *G. aristata,* which bloom at the same period and average 2–4 ft. high, include : *Aurora* (orange-yellow) ; *Gladys* (yellow) ; *grandiflora* (a strong-growing sort with yellow flowers) ; *James Kelway* (bright red) ; *John Stormonth* (large red flowers edged yellow) ; *Lady Exeter* (yellow with chocolate brown centre) ; *Lady Gay* (yellow marked deep red) ; *Lady Rolleston* (bright golden-yellow) ; *Mary Fergusson* (yellow and pretty rose centre) ; *Masterpiece* (bright crimson-red and narrow ring of

yellow); *Moonlight* (yellow with red zone); *Rownham Queen* (bright carmine with pale yellow ring); *Sunset* (brilliant crimson-red with yellow margin); and *William Clibran* (orange-yellow).

G. lanceolata.—This beautiful species bears yellow or orange-yellow flowers from June onwards throughout the summer, but it must not be regarded strictly as perennial. It averages 1½ ft. in height.

GALANTHUS.—See *SNOWDROP.*

GALASIA.—Now included in the genus *SCORZONERA.*

GALATELLA.—Now included in the genus *ASTER.*

GALAX (FAIRIES' WAND. Nat. Ord. Diapensiaceæ).—A beautiful shade-loving plant for the border or rock garden, with large, round leaves becoming tinted in autumn. It is propagated by division in spring. Only one species need be troubled with :—

Galax aphylla.[1]—An evergreen creeping plant. Flowers white in long dense spikes. Soil peaty. Flowering Period, all the summer. Height, 1 ft.

GALBANUM PLANT (*Ferula galbaniflua*).—See *FERULA.*

GALEGA (GOAT'S RUE. Nat. Ord. Leguminosæ).—This is an eminently desirable, hardy herbaceous perennial in every way, provided it is given plenty of room. It is useful for the wild garden, herbaceous border, mixed border, or shrubbery border, and highly attractive with its small pea-like flowers. Established plants form large bushes, which are completely covered all over with bloom. Sprays of this are useful for cutting or for forming bouquets.

Culture.—The plant is one of the very easiest of all perennials to grow; it will succeed in town or country; in hottest sun or in light shade; in soil of sand, or in strong clay; and it is not in the least particular as to manure, provided that such nitrogenous fertilisers as Calcium Nitrate, Calcium Cyanamide, Sulphate and Nitrate of Ammonia, and Nitrate of Soda and Potash do not come its way. It may be successfully planted any time from October to March, but requires staking early and securely in the growing season. No watering or feeding is necessary save in the hottest summer. The plants may easily be propagated by seeds sown in the usual way, as described in our article on *PERENNIALS: GENERAL CULTURE OF*; they may also be increased by division of the roots in the autumn or early spring.

What to Grow.—There is no great abundance of sorts, but we recommend the following :—

Galega Hartlandii.—This, in reality a variety of *Galega officinalis*, is usually offered as a species, and is probably one of the most popular sorts. Its flowers are pale blue and white, unspeakably lovely, and produced with glorious profusion. The blooming period is a long one; often the first flowers open about the end of June, and the last one not until the end of September. The height averages 4–5 ft.

G. officinalis.—The type plant, or WILD GOAT'S RUE, is blue. The varieties of this, *alba* and *carnea plena*, are white and double pink respectively, and are more beautiful. They all flower from June onwards to the end of the summer, and range in height, according to circumstances, from 2½ ft. to 5½ ft.

G. orientalis.—This blue-flowered sort is not much grown. It flowers from July onwards, and is not so tall

[1] The CARPENTER'S LEAF of Kew.—EDITOR.

as the rest, its greatest height being 1 yd.

GALEOBDOLON.—Now included in the genus *LAMIUM.*

GALEOPSIS (HEMP NETTLE. Nat. Ord. Labiatæ).—This is a genus of troublesome, hardy annual weeds which should on no account be cultivated, though they are not infrequently offered in catalogues. Several species are grown at Kew, of which perhaps the most notable is *G. Tetrahit,* the BEE NETTLE.

GALINGALE (*Cyperus longus*).—See *CYPERUS.*

GALIUM (BEDSTRAW. Nat. Ord. Rubiaceæ).—This is a genus of hardy annual and hardy perennial plants which are strong-growing weeds, and quite unsuitable for cultivation in gardens. *G. Aparine* is the weed GOOSEGRASS, described under that name in our article on *WEEDS.* A large number of species are grown at Kew. Of these we may mention *G. Cruciata,* the CROSSWORT BEDSTRAW; *G. Mollugo,* the HEDGE STRAW; and *G. verum,* the LADIES' BEDSTRAW.

GALL WEEVIL.—See under TURNIP AND CABBAGE GALL WEEVILS in *INSECT PESTS.*

GALTONIA (Nat. Ord. Liliaceæ). *Galtonia* (Syn. *Hyacinthus*) *candicans* is a fine, hardy, bulbous and August blooming plant. The pendulous bell-shaped blooms are white, and are borne on tall stems about 2–4 ft. high, according to the soil and position. They look well when associated with the scarlet *Gladiolus brenchleyensis.*

Culture.—Any ordinary soil suits the plant. The bulbs should be set in October, and slight protection given during the first winter, after which they will take care of themselves. Galtonias are splendid as pot plants for the conservatory.

J. J. & E. T. E.

GALVANISED WIRE NETTING.—See under WIRE NETTING in *GARDEN NETTING.*

GANDAVENSIS GLADIOLI. — See *GLADIOLUS: CULTURE OF.*

GANYMEDES.—Now included in the genus *NARCISSUS.*

GARDEN ACCOUNTS. — See *ACCOUNTS: GARDEN AND ALLOTMENT.*

GARDEN ALTERATIONS.

As the autumn and winter seasons approach, a good many gardeners become mildly excited in anticipation of the work before them. "Here's another chance to alter things," they say, and they look forward to a fine time, making all manner of unnecessary alterations in a vain attempt at improvement.

It is about this craze for garden alterations that I want to speak in this article, in the hope that some of those who read may have mercy on their gardens, and spare their own hands.

The craze for constant alteration is really a very foolish one. It is childish. A child, especially a little girl, can never leave things alone. It always wants to be altering things, and at length it manages to spoil them utterly, and then begins to cry. Its mother is naturally cross with it for spoiling something pretty.

And the present writer, who is privileged to visit many gardens every year, is more than cross when he sees what was a beautiful garden last year spoilt and ruined this year because of the childish craze for alteration. A child can be smacked if it is naughty enough wilfully to spoil something beautiful, but alas, the gardener or innovator of these new uglinesses, the spoiler of all that is fair and lovely, the man who is crazy on garden alterations, cannot be treated similarly. One has to

grin and bear it. True, one can protest in words; but what is the use? The deed is done.

One wonders where the pleasure of these constant alterations comes in. Certainly it ought not to be a pleasure to pull to pieces what has been a lovely picture during the past summer. If it is, there is surely something radically wrong, and the gardener would be well immediately to consult his doctor. If I were his medical adviser I would certainly prescribe a dose of quinine, or some other equally nasty physic!

But, joking apart, gardeners really ought to try to leave alterations much more alone than they do. In this quickly-moving age there is little sympathy with Nature; man thinks he can do all, and that Nature can do nothing. He is very wrong, however, and he knows it in his heart, yet to prevent Nature calling him to order, and toning down his horrors with her own sweet beauty, he must for ever be rushing on, doing one thing and then another, making some new scheme to-day, and being ready to pull it to bits to-morrow, all because he fears Nature will show her hand, and make his garden what it might be—"a thing of beauty and a joy for ever."

A day of reckoning will come, though sometimes it tarries longer than most true garden lovers would wish. That gardener who has gone "the whole hog" and indulged to the full his passion or his craze for alteration, will wake up one morning with his eyes newly opened. He will look out of his window and, instead of seeing what yesterday he believed was pretty, he will see nought but the intense ugliness which now exists. He will rub his eyes as a schoolgirl does when she has woken up from a dream, and he will wonder indeed why he has been such a true fool. Dame Nature chooses her own time to open his eyes, wily old lady that she is, and instead of letting him see aright just before the time for alteration commences, she opens his eyes three months in advance.

So this gardener is punished month by month, day by day, hour by hour. He has to own the terrible results of his own work—brought on by an insane desire to alter. And his punishment is greater still. A specialist is called in, and says it will be almost impossible to make that garden lovely again.

Readers, I have painted a dark picture, I know, but I have painted it purposely. I want to see this craze for thoughtless garden alteration curbed, and curbed by every gardener. Think before you act, plan before you plant, study ere you sow, or sooner or later you will be punished.

Nature is merciless in the end. She lets you go as far as you like up to a point, and then she steps in. You realise too late what you have done, and she laughs at your chagrin.

And now for a practical conclusion to all this talk. Observation has proved that it is utterly impossible to know the results of any new plan, alteration, or scheme within the first year in which it was carried out. Man does the rough work, but Nature tones it down, and one cannot ever be certain, till at least two years have passed, as to whether one has increased or lessened the beauty of the whole.

One must think and watch and plan. Dame Nature in her many moods *must* be studied if alterations are to produce any results worth attaining. One must foster a passion for loveliness and learn the magic of colour and the glory of form, and to study Nature in her many moods.

If we don't, we shall suffer. Should there be the slightest doubt of the desirability of making any single garden alteration in the gardener's mind, it is best to leave it completely alone until such a time as we are convinced of the wisdom of undoing what has been done in the past with Nature's help.—E.

GARDEN APPLIANCES.

In purchasing garden appliances, the main things to consider are utility and the effects of their use. The garden ought to be made productive at the least cost, and with a minimum of manual labour. Economic labour-saving contrivances are therefore valuable accessories. The following appliances will be found most useful, and in their possession and use in every way helpful, giving better results and greater pleasure than by "making shift" with less handy or less effective tools:—

Barrows.—Barrows should be very strong, and are better painted, as they are often exposed to the damp, and are used for wet earth and watery manure. A good class is that made with elm tops and ash wheels. Light barrows are made of galvanised iron with wrought-iron frames and wheels. Two very useful sizes are 28×23 ins., and 30×26 ins., both larger and smaller sizes being obtainable. Another variety is an "easy tip" barrow with rounded ends, and highly useful when trenching ground or wheeling manure up into a hotbed frame.

Cultivators.—Although cultivators are by no means essential, they are decidedly useful to the gardener, for they save time, and by their construction prevent much waste of labour. For instance, single-wheel cultivators fitted with a pair of 6-inch hoes and cultivator teeth are handy. What are known as the "Planet-Junior" garden implements are useful appliances; one of the larger of these tools, including a pair of 6-inch hoes, a pair of ploughs, two pairs of cultivators, and a pair of leaf lifters, is exceedingly handy.

Garden Rollers.—Single and double cylinder rollers are sold for garden purposes, the latter being much the best for even small lawns and paths, since they admit of being turned the more easily. The handles should be well balanced and the bearings accessible for oiling. A further kind have hollow cylinders which can be weighted by filling with water. Water-ballast rollers are very good for large lawns and for cricket pitches. Weights vary; the amateur is, however, recommended to use a roller which can be drawn or pushed with comparative ease. Frequent rolling does much good to young lawn grass, and spreads the roots, especial benefit ensuing in the early spring, when the lawn requires well rolling to press down upheavals caused by worms and other creatures, and generally get it into good condition for the lawn-mower. The best time to roll is after rain, when the ground is moist. Garden walks also can only be kept in good condition by frequent rolling.

Hose Pipes.—Hose pipes should be of good rubber strengthened in various ways. The strength is denoted by the number of layers of insertion placed in the material to preserve the rubber resistance, and also to afford the proper stiffness to maintain a steady flow of water, the makers terming this as one-, two-, or three-ply. Another make of rubber hose much favoured for use on rough and uneven lawns and ground is ribbed; and a type further strengthened by the use of wire in the coils is known as armoured hose—the better qualities being tested to withstand pressure of about 250 lb. A seamless woven cotton hose, rubber lined, stands very high pressure, some of the pipes being tested to 1000 lb. pressure. Hose pipes are usually made of best grey rubber, but red rubber has been much favoured for garden purposes. The hose is supplied in lengths of 60 ft. or 120 ft., the most convenient sizes being ½ in., ⅝ in., and ¾ in. in diameter.

Hose Pipe Fittings.—Fittings for all the regular sizes of hose pipes are sold by ironmongers and sundriesmen; these include brass tubes for attachment to taps, and provision for the use of several kinds of jets and sprayers, the ends being threaded and easily inserted in the pipe, to which they may be attached by a little copper wire firmly bound. On the inlet end of the hose pipe patent tap unions are needed; by these the water supply from the ordinary taps is secured without any waste or leakage. The various jets and spreaders include sprinklers, and copper delivery nozzles for filling cans, barrels, etc.

Hose Reels.—There are two kinds of

reels on which rubber hose can be safely kept without any fear of breakage or "kinking." These are the circular reels, cheap, and easily handled or carried, and the larger reels, wound by a wheel with a handle and run on a wheeled carriage of suitable size.

Mowing Machines.—Much might be written about the different classes of lawn mowers, English and American. It would, of course, be invidious to select any one make for special mention, but the buyer is recommended to purchase a modern machine made by a well-known, old-established maker, for in these things it is the little improvements added from time to time which go towards securing a good and reliable grass-cutter. An all-round machine for lawns should have a movable grass collecting box, in order that the grass may be left lying on the lawn or not at will. The English machines have several knives upon the barrel and a strong cutting blade underneath. Some machines with fewer knives are apt to leave ridges upon the lawn, especially if it is at all uneven. Screw adjustments regulate the depth of cut, and raise or lower the back roller. Some machines are fitted with ball-bearings, which make them run very smoothly. Strength and lightness are the two greatest attributes. The two chief types are those with chain or gear drive. All machines are made in sizes varying from 8 ins. to 14 ins. cut. For small gardens, machines with 10 ins. or 12 ins. cut are most suitable. Larger machines are fitted with ropes for pulling, and there are arrangements for pony and horse draft. A mower driven by motor power will be needed for very large areas. *Lawn Sweepers* are useful on large lawns and grounds. An edge-cutter attachment which can be guided with ease is a useful addition to the machine. The bearings of both mowers and sweepers easily clog if not cleansed and well oiled, so the machines should have this little attention immediately after use.

Propagating Frames.—It is not necessary to describe here the larger kinds of frames, lean-to greenhouses, and other structures which belong more to the professional gardener than to the amateur. It is, however, essential that propagating frames and hand-lights should be used to secure the full economic benefit of gardening, and the rearing of plants for bedding out and potting. The open-roof frames with hinged lights on both sides are useful, and even the smaller sizes made from packing cases and old glass come in handy, where there is not much spare space. Cap glasses with zinc frames are also useful, the best sizes being those with diameters varying from 18 ins. to 21 ins. Oblong hand-lights 25×18 ins., 32×20 ins., and 36×24 ins., are recommended. A useful addition to these small frames or hand-lights is a miniature heating apparatus easily made by using a pan to hold water, some slates to cover it, and a lamp underneath in a box helping to heat it. Provided ventilation of the bottom chamber is arranged for, no harmful fumes will reach the frame above. This contrivance—most useful for striking all manner of cuttings quickly—is known as a *Propagator*.

Seed Protectors.—The small wire arches known as "seed protectors" are very useful indeed to keep off the birds when the young seeds are springing up. They should always be used for peas to preserve the plants, and secure the continuity of the row. The protectors are made in standard sizes, 36 ins. long by 6 ins. wide, and ends are also provided to prevent the birds from entering the row.

Sieves.—These are useful for providing the fine soil so necessary when sowing small seeds. Mould sieves have strong iron wire meshes and oak rims. The best have two or four meshes to the inch, the usual sizes being 14 ins. and 18 ins. in diameter. Sieves for sorting seeds and separating seed potatoes are also obtainable. Sieves for gravel and stones are made with strong wire, the meshes being ¼ in., ½ in., and ¾ in., and the sieves about 20 ins. in diameter. They are also known as *Riddles*.

Sprinklers.—There are some very profitable sprinklers on the market which can be moved about and handled quite easily; they are mostly of galvanised iron, and often on frames of cast iron, supplied with revolving arms and heads, the better ones being nickel-plated, rustless, and preferably fitted with ball-bearings. The *Garden Shower* is a circular ring with no loose parts, and is readily attached to the pipe; it is a capital and inexpensive invention for a small lawn.

Syringes.—Syringes of metal and of brass are much used in gardens and greenhouses for spraying roses and other plants; all the better kinds are

of brass, but the cheaper ones are made of zinc or other metal. Some are made with fluted cylinders and are very strong. Two or more roses of different fineness are supplied with the more expensive kinds, and in some instances sprayers are also available. The ordinary types are about 16–18 ins. in length, and vary from 1¼–1½ in. in diameter. Among the favourite specialities are patent drip-preventer syringes; others have special spraying nozzles for spreading insecticides. The *Dewspray Self Container Syringe* is a capital invention, most useful to rose-growers. Another little syringe, mostly for ladies' use, is the *Baby*, a pretty syringe for destroying insect pests on roses and other plants. Syringes should be cleansed frequently, and if necessary the "tow" on the plunger renewed and tallowed to make it run easy.

Thermometers.—A thermometer of some kind is an absolute necessity to all gardeners. The common boxwood variety serves some purposes well enough, but a registering thermometer is necessary to record the fall of temperature during the night or in very cold weather. Some for greenhouse use are made with cast-iron frames, and those with opal scales are the more easily read as well as more lasting. Special instruments are made for testing the heat of hotbeds and frames. These are usually in a long wooden frame.

Water Barrows.—A water barrow is in many places a necessity, especially where there is no town supply of water for the hose pipe. Water barrows should be made of galvanised iron, and should have strong wrought-iron frames and riveted rims, and run freely on large wheels. The usual stock sizes hold respectively 12, 20, 30, and 40 gallons. What is called a *Garden Engine* is a water barrow to which is attached a force pump with sprayer and rose—an exceedingly handy contrivance in a fruit garden.

Watering Pots.—The ordinary watering can or pot is well known. Such cans are made of galvanised or black iron, and preferably painted; they should also be fitted with brass or copper roses. There are several sizes, varying from 3–12 pints or more for light work; heavier and stouter cans holding from 1½–4 gallons, though the last named are too heavy when filled for amateurs' use. The short-spouted variety are mostly favoured, but for watering plants in greenhouses and on shelves those with long, and extra long, spouts are recommended. What is known in the trade as a lady's can, holding about 1 quart, is a useful appliance in a small conservatory. Among other varieties are strawberry water pots and the nurseryman's can with a very long spout, fitted with two or more roses to suit special work. A 6-quart can is in our opinion the most handy size.—F. W. B.

GARDEN CHEMICALS : List of.

Although the gardener would have to set up a druggist's store if he were to keep all the chemicals in the list below by him, he should nevertheless keep by him small quantities of the more important and useful chemicals which are marked with an asterisk. The quantity he will want will vary from an ounce or two in the case of Hellebore Powder to a hundredweight or so of such as Nitrate of Soda. The chemicals in the list are mostly given under their true chemical names, but a few popular names such as Liver of Sulphur (Potassium Sulphide) are included. It is assumed that the reader is aware that Nitrate of Potash is the same as Potassium Nitrate, Nitrate of Lime the same as Calcium Nitrate, Nitrate of Soda the same as Sodium Nitrate, and so on. It should, however, be specially noted that "Chloride of Lime" is not Calcium Chloride but Calcium Hypochlorite, an oxidised and lower grade compound.

List of Garden Chemicals.

Acid Sodium Phosphate.
Alum.
Aluminium Metal.
Aluminium Sulphate.
Ammonia (Liquid).
Ammonium Carbonate.
Ammonium Chloride.
Ammonium Chromate.
Ammonium Hydroxide.
Ammonium Molybdate.
*Ammonium Nitrate.
Ammonium Phosphate.
*Ammonium Sulphate.
Ammonium Sulpho-cyanide.
Aqua Fortis (Nitric Acid).
Arsenic (*White*).
Barium Carbonate.
Barium Chloride.
Basic Slag.
Bees' Wax.
Benzine.
Beta Naphthol.
Blue Stone. (See Copper Sulphate.)
Bone Ash (*Black*).
Bone Ash (*Purified*).
Bones, Degreased.
Boracic Acid.
Borax.
*Bordeaux Mixture and Paste.
*Burgundy Mixture.
Calcite.
Calcium Carbide ("Carbide").
Calcium Carbonate (Chalk).
Calcium Chloride.
*Calcium Cyanamide (Nitrolim).
Calcium Fluoride.
*Calcium Hydroxide (Slaked Lime).
*Calcium Hypochlorite (Chloride of Lime).
Calcium Mono-orthophosphate.
Calcium Di-orthophosphate.
Calcium Tri-orthophosphate.
*Calcium Oxide (Quicklime).
Calcium Sulphate (Gypsum).
Calcium Sulphide.
Carbide. (See Calcium Carbide.)
Carbolic Acid.
Carbon bi-sulphide.
Carborundum.
*Caustic Alkali Washes.
Caustic Paraffin Emulsion.
Caustic Potash.
Caustic Soda.
Chalk (*Precipitated*).
Charcoal (*Animal* and *Wood*).
Chile Saltpetre (Sodium Nitrate).
*Chloride of Lime (Calcium Hypochlorite).
Cobalt Nitrate.
*Condy's Fluid.
Copper Aceto-arsenite.
Copper Arsenate.
Copper Carbonate.
Copper Nitrate.
*Copper Sulphate (Blue Stone).
Copperas. (See Iron Sulphate.)
Corrosive Sublimate. (See Mercury Chloride.)
*Creosote.
Cupram.
Emery and Emery Paper.
Epsom Salts. (See Magnesium Sulphate.)
Ferric Chloride.
Ferricyanide. (See Potassium Ferricyanide.)
Ferrocyanide. (See Potassium Ferrocyanide.)
Ferrous Ammonium Sulphate. (See Iron Ammonium Sulphate.)
Ferrous Sulphate. (See Iron Sulphate.)
Fluor Spar.
Formaldehyde.
Formaline (similar to Formaldehyde).
Freezing Salt.
Gaslime.
Green Vitriol. (See Iron Sulphate.)
Guanos (Various).
Gunpowder (for squib-making in the destruction of Wasps' nests).
Gypsum. (See Calcium Sulphate.)
*Hellebore Powder.
*Hydrochloric Acid (Spirits of Salt).
Hydrocyanic Acid.
Hydrofluoric Acid (too dangerous to keep).
Hydrofluorsilicic Acid.
Iodine.
Iron Ammonium Sulphate.
Iron Sulphate (Green Vitriol).
*Kainit.
*Lead Arsenate.
Lead Carbonate.
Lead Nitrate.
Lead Oxide (especially the kind known as Red Lead).
Lead Sulphate.
*Lime. (See article on *LIME*.)
Lime Sulphur Wash.
Limestone (crushed grit or powdered).
Linseed Oil.
Litharge (Lead Oxide).
*Liver of Sulphur (Potassium Sulphide).
Magnesium Ammonium Phosphate.
Magnesium Carbonate.
Magnesium Chloride.
Magnesium Sulphate (Epsom Salts).
Mercury Chloride.
Mercury Sulphide.
Methyl Alcohol.
*Methylated Spirits.
Microcosmic Salt.
Muriate of Potash (Potassium Chloride).

Muriatic Acid (same as Hydrochloric Acid).
*Naphthalene.
*Naphthalene-Paraffin Emulsion.
*Nicotine Washes.
Nitrate of Lime. (See Calcium Nitrate.)
Nitre (same as Potassium Nitrate).
Nitric Acid (Aqua Fortis).
*Nitrolim (same as Calcium Cyanamide).
Nitro-sulphuric Acid.
Orthophosphoric Acid.
Oxalic Acid.
*Paraffin Emulsion.
Paraffin and Naphthalene Emulsion.
*Paraffin Oil.
Paranaph (same as Paraffin and Naphthalene Emulsion).
*Paris Green.
Pearl Ash.
Permanganate. (See Potassium Permanganate.)
Petrol or Petroleum.
Phosphoric Acid.
Plaster of Paris.
Potash. (See Potassium Carbonate.)
Potassium Carbonate.
Potassium Chlorate.
*Potassium Chloride.
Potassium Chromate.
Potassium Cyanide.
Potassium Dichromate.
Potassium Ferricyanide.
Potassium Ferrocyanide.
*Potassium Hydroxide (Caustic Potash).
Potassium Monosulphide.
Potassium Muriate (same as Potassium Chloride).
*Potassium Nitrate (Saltpetre or Nitre).
*Potassium Permanganate.
Potassium Sulphate.
*Potassium Sulphide (Liver of Sulphur).
Prussic Acid (same as Hydrocyanic Acid).
Pyrethrum Powder.
Quassia (not, strictly speaking, a chemical).
*Quicklime (Calcium Oxide).
*Red Lead.
*Salt, Common Kitchen (same as Sodium Chloride).
*Saltpetre (same as Potassium Nitrate).
*Saltpetre, Chile (same as Sodium Nitrate).
Shellac.
Silver Nitrate.
Soda Emulsion.
Soda Lime.
*Soda, Washing (same as Sodium Carbonate).
Sodium Ammonium Hydrogen Phosphate.
*Sodium Carbonate (Washing Soda).
*Sodium Chloride (Common Salt).
*Sodium Hydroxide (Caustic Soda).
*Sodium Nitrate (Chile Saltpetre).
Sodium Orthophosphate.
Sodium Phosphates.
Sodium Pyrophosphate.
Sodium Silicate.
Sodium Sulphate.
Sodium Sulphide.
Soft Soap.
*Soot.
*Spirits of Salt (same as Hydrochloric Acid).
Sulphur (*Black*).
*Sulphur (*Flour of*).
*Sulphur (*Liver of*).
Sulphuric Acid.
Sulphuric Ether.
Sulphurous Acid.
*Superphosphate.
Thomas' Slag. (See Basic Slag.)
Tobacco Powder.
*Turpentine.
*Vaseline.
Vitriol, Oil of (same as Sulphuric Acid).
*Washing Soda (same as Sodium Carbonate).
*White Lead.
*Whiting.
Zinc Carbonate.
Zinc Sulphate.—E.

GARDEN CHEMISTRY.—See *CHEMISTRY FOR GARDENERS.*

GARDEN CRESS.—See *LEPIDIUM*, also under MUSTARD AND CRESS in *SALAD PLANTS.*

GARDEN DESIGN ON MODERN LINES.—Gardens vary in extent from a few rods to many acres of ground, and are infinitely varied in outline and circumstance. No single book can therefore deal with every problem connected with the subject of garden arrangement and design.

It may be possible, however, to summarise in a short article a few leading ideas serviceable to the amateur who is interested in planning what may be described as an "average" garden.

Zeal without discretion accounts for a good deal of the disorder into which many gardens drift. When

no definite idea has prevailed, a day is sure to arrive when it is found desirable to pull things together into one coherent scheme. Unfortunately it is often too late then, unless one has the courage to sacrifice some treasured possessions.

When a practised designer begins to plan a garden the first thing he does is to collect and tabulate his data—even though he may do so unconsciously. He next establishes in his mind those matters which he considers essential to the case. He then allows his imagination to play round what is desirable, and finally he adjusts to the hard facts of practicability what he would wish to do if he had a free hand.

With regard to data—the first thing required is a plan of the site showing things exactly as they are. The plan should be to a conveniently large scale, and if the contour of the ground is uneven, levels should be taken and figured on the plan. The ground plan of the house should be accurately indicated with all outbuildings. The positions of all doors and of the windows of important living-rooms must be marked on the house plan.

The site is next carefully examined, and the most extensive and picturesque vistas as seen from the house, are noted; existing trees and other features worth preserving or offering a possible nucleus for characteristic development should be carefully observed—a wet ditch may be such an instance. Consideration must be given to positions exposed to cold or rough winds and undesirable objects, either on the site or beyond the boundary which require screening—or there may be some attractive vista or feature outside the garden worth incorporating into a view.

The ground must be carefully studied for the purpose of ascertaining the most sunny, shady, or unfavourable spots, the need for drainage, the nature of the soil and subsoil, the resources of the site (stone or gravel, for instance, may be valuable, and excavation may give an opportunity for an interesting sunk garden or diversity of level), the kinds of trees and shrubs best suited to the locality, and other similar matters.

All the foregoing points will be kept at the back of one's mind in working out the scheme of the garden. In considering necessities I place first the absolute importance of planning a garden within the capacity of the owner, not only in respect of original expenditure, but in the cost of maintenance. It is fatal to efficiency to overburden the garden staff with work beyond their power. It results in certain disappointment to the owner and disheartens the men. Essentials vary according to circumstances, but a few requirements are common to every garden.

A point of real importance is the matter of access to the front door. Bad judgment in the arrangement of carriage drives spoils the best possibilities of many gardens. The manner of approach is the first thing to consider in any garden plan. This road or path is used more than any other in the garden, and deserves to be made as attractive as possible—not merely walled off by dull high hedges. A carriage drive should not be unnecessarily long, or useful garden ground may be wasted. A forecourt should not be made at all if it cannot be sufficiently large for its purpose. For a small house where carriage or car are rarely used it is better to have simply a wide path to the front door. Separate and private access to the back door is, of course, necessary, and the arrangements

for connection with stable or garage must be as convenient as possible.

With regard to garden paths which are bare necessities, one would first consider those required for circulation round the house, if the word may be used in connection with paths that should be straight and parallel to the main walls of the building. Broad terrace paths on the principal garden front or fronts are of chief importance. They form the bases of the whole garden plan. A simple principle is to provide one continuous walk round the gardens affording the longest and most complete tour of inspection of all the chief features of attraction. Of course, additional paths are generally wanted, but gravel paths should be reduced to a minimum—grass walks being much more pleasing. Stone paving or brick paths (placed on edge) are attractive. A novice generally enjoys working out ingenious designs for a formal garden patterned in gravel. It is a phase through which most garden designers pass. Sooner or later experience and observation invariably bring home the truth that simplicity of outline and directness of plan afford the best results when one has to rely upon a natural medium such as plants for picture effects.

Referring again to what is necessary, dry access must, of course, be given to the vegetable garden from the kitchen.

A kitchen garden is now essential so far as space permits. It will need a favourable but inconspicuous position. The size must be determined by the probable needs of the household and the proportions generally of the whole garden. The kitchen garden may be intersected by flower borders or a pergola and be thus brought into relation with the pleasure garden.

If the area does not suffice for planting an orchard, fruit trees may be placed on the lawn or grass for decorative effect. The bloom of apple, plum, or cherry trees is quite as beautiful as that of kindred trees grown only for their flowers.

If glass is required, a really suitable position should be reserved. A lean-to greenhouse should face due south; a span-roof structure should run north and south if possible. A greenhouse or conservatory is never a picturesque object in a pleasure garden.

In certain parts of the garden planting for the purpose of shelter and screening may rank as necessities. It will assist in shaping the framework of a design if such positions and the situation of the other details already referred to are provisionally marked on the plan.

Important details often overlooked until the need arises are positions for potting shed, tool houses, etc., and rubbish heap. Every well-ordered garden *must* have a convenient place for waste purposes, kept, of course, well out of sight.

We now come to the crux of the affair—the question of design.

Still following the matter on lines of common sense, one will first consider what features are particularly desired. These may include all or any of the following: croquet, tennis, or other playing lawns; Rose Garden; Gardens for annuals or other favourite flowers, such as Tulips, Iris, or Lilies; Rock, Water, or Bog Gardens; herbaceous borders; garden house; Pergola, or special sections for climbing plants; Specimen shrubs; and many other features which may be fancied.

The earlier study of the site may go far towards dictating or suggesting the best situation for any one or

other of the details named, and the skeleton of the scheme is advanced a stage by again indicating provisionally the area required and the positions (positions not yet the design) upon the plan.

The decisions already arrived at are, however, merely so many dry bones, which can only be brought to life by the quickening power of imagination. This is a power which may be stimulated, but cannot be conveyed from one person to another. No one can be taught how to design. The would-be designer must teach himself by applying lessons learned patiently from the best examples and expressing them by the force and fertility of his own imagination.

The chief aim in modern garden arrangement is pictorial effect combined with interest in detail. Fortunately these are both best served by designs which are simple in principle. The first objective in a picture is good composition, and the elementary principle of good composition is the achievement of what is called unity—that is the predominance of one object or point of importance to which all other parts and details are subordinate. The determination of this object or point is the first step towards making a design of the whole or of any part of the garden. Every subordinate garden complete in itself must have a similar focal point or chief object of interest.

It will probably be agreed that the most desirable gardens are those which contain the largest possible number of charming pictures. These pictures should be arranged to be seen from the most important points on the house fronts, and at changes of axis in the garden.

Intricate elaboration in design is far from necessary for pictorial effect. It is in fact confusing and detrimental unless carried out by a master hand. The beauty of a garden is determined by what one sees in elevation, not by the excellence of a design as it appears on paper. A garden is made beautiful partly by the things that are planted in it, but chiefly in consequence of the positions they occupy in relation to each other.

Any garden which is planned sensibly to the ordinary mind, logically in so far that a reasonable justification can be made for everything that is done, and unaffectedly in harmony with the purpose and pretensions of the house, is well designed. Such a garden can generally be made charming by a person who has a good eye for a picture, a sound knowledge of the resources of horticulture, and a feeling for nature.—E. W.

[The article just given is full of sound advice, and should be useful to any gardeners whether young or old. So much nonsense has been talked about Garden Design that it is a real relief to read the remarks of one who is such a sympathetic expert in his subject. The three possessions summed up in the last sentence need special comment.

Gardeners should cultivate an eye for a picture. They should by study be able to tell more or less at a glance what is so "radically wrong" with any badly designed gardens they may enter. This will only come with study, but it is worth the study, and an eye for a picture will largely prevent failure or disappointment in garden design.

Secondly, a sound knowledge of the resources of horticulture is absolutely essential to be a successful garden designer. We must know the greatest and the smallest possibilities of every plant or tree we propose to use. If not, we shall be riding for a fall. Such knowledge

can only be acquired by a good deal of patient study and by constant observation.

Thirdly, sympathy with or a feeling for nature is essential. Feeling of any kind in these twentieth-century days is, if shown, mocked at or considered childish, and we Englishmen are becoming experts at curbing every atom of feeling that there may be in us. But why? Feeling is not given us for the purpose of being for ever held back, for ever curbed or thrust aside. We are all of us human beings and not machines. But if we are continually curbing our feelings we can soon kill them, and then we are merely human machines. To revert to our point that a feeling for nature is essential to the successful garden designer, we may say that it is the fashion to do one's best to kill this. A gardener, instead of cultivating this beautiful human passion, cultivates a stern matter-of-fact manner instead. He leaves it to his employers, schoolgirls, or grown-up ladies to gasp, "Oh, how lovely!" when they see a beautiful flower or a sheet of bloom in garden or wood. But let him not ban feelings, for if he has not a feeling for Nature in all her moods he cannot hope to use her resources successfully for his garden design.

Lastly, the gardener should surely keep his eyes open wherever he goes. He should deign to study other gardens, instead of despising them, or deciding, as he so often does, without the slightest reason, that "they are not so good as ours, and so are not worth troubling about." He should view every garden he may have a chance to enter with an open mind, and analyse it critically in his mind. He will then see not only its failures, but its many successes—little beauty spots of which he had no idea will seem to spring up and dance before his eyes. It is very likely that he will learn something of great use to him when it comes to modifying the design of his own garden, which up to now he considered faultless. —EDITOR.]

GARDEN DESIGN ON OLD-FASHIONED LINES.—When considering the older gardens in relation to those of quite modern times we note that, except in special cases, they were much smaller in size, and for the most part closely walled or fenced. In the early Middle Ages the largest gardens were those attached to the religious houses, almost entirely for food production, with a few flowers only for ceremonial decoration. With few exceptions it is not till Tudor times that we know of gardens purely for pleasure, but then, with the new security of the country and the building of noble houses of the palatial, and many more of the manorial classes, the need was felt for gardens for delight, and every house must have its suitable accompaniment of flowers and blossoming shrubs and trees. The earlier gardens were nearly always of square form, and enclosed by wall or moat, for though the actual need of means of defence no longer existed, the feeling of a desire for safety and seclusion remained, and deer and wolves were still at large. Whether the house was large or small, it was usual to have a quiet forecourt between it and the road, with a paved path to the door passing between plots of grass to right and left, but without any special display of flowers; and perhaps no pleasanter way of access to a house has ever been devised. A large place would sometimes have two such forecourts with a handsome

gatehouse between the two. The flower garden was on the farther side of the house, with a wide terrace running close to the building and overlooking the parterre. It was usual for this garden to be on a level a few feet lower than that of the house, with either a central flight of steps, or steps down at each end of the terrace. Later, in Stuart times, came ornaments in stone, marble, and lead. The lines of the garden were kept straight and orderly, and those gardens that remain or that have been designed with the same intention have a kind of homely dignity that accords well with our national character and our English landscape, as also with the houses to which they belong. Such gardens are specially suitable to the dignified style of building of the eighteenth century, when they had settled down into a character that may be described as having the qualities of sanity, serenity, and sobriety. For all good gardening has its foundation in common sense. The old designer accepted the conditions of the place, and moulded them to the most reasonable form; he avoided anything of strain or affectation, and drew no line that was not to some good purpose or definite intention. It is true that, when our gardening began in Tudor times, various accessories were employed that we should now consider frivolous and unworthy, such as gilded bird-cages and hanging objects of coloured glass to flash in the light. But as our gardening grew to more definite form these were cast aside, and our English garden went on its own quiet way, avoiding also in later times the lavish over-adornment of the French, and the petty intricacies of the Dutch styles. It would be well in these days, when gardening possibilities are so vast and the designer may be tempted to run wild, that he should restrain himself and strive to regain the older simplicity and charm, remembering that the first purpose of a garden is to be a place of quiet beauty such as will give delight to the eye and repose and refreshment to the mind.—G. J.

GARDEN DIARY: THE KEEPING OF A.—One of the very biggest mistakes the gardener can make is not to keep any record of his work in the form of a Garden Diary. The practical value of such a diary, if properly arranged, is very great indeed, and by means of its Index, or its Sowing Table, the gardener can turn up anything he happens to want in the course of a minute or two. The diary is a great aid to successful gardening—greater than can easily be explained in a few words. An example of its use will be found below:—

March 15th.—Sow seed of Godetia The Bride.

April 3rd.—Sow more seed of Godetia The Bride.

April 15th.—Those plants of Godetia The Bride sown March 15th look small and spindly. Probably I sowed them too early.

April 21st.—Godetias sown March 15th look very poor and spindly, but those sown April 3rd very strong and healthy.

May 30th.—Pretty certain I sowed that Godetia The Bride too early (March 15th), for that sown April 3rd is far better.

June 15th.—Yes, I did sow that Godetia too soon, for the plants sown on April 3rd opened their first flowers to-day.

June 30th.—Remark on June 15th about Godetia The Bride sown on March 15th confirmed to-day, when

it flowered for the first time—a fortnight *later* than that sown on April 3rd, and even now the flowers are very poor, hardly worth gathering in fact.

An example of the Sowing Table is now given :—

PART OF SOWING TABLE, 1919.

NAME OF CROP.	WHEN SOWN.	REMARKS LATER AND DURING SEASON.
Artichoke, Jerusalem	March 20th	Sown too late. Another gardener put his in on February 20th, and got much better crop.
Carrots . . .	March 3rd	Splendid crop.
Parsnips . . .	March 30th	Too late. Must sow at least a month earlier next year.
Salsafy . . .	March 15th	Good crop.
Swede Turnips .	April 3rd	Poor crop. Am told they should have been sown early in February, hence probably my failure.

The examples just given will show the practical value of such a Garden Diary. Besides recording failures and successes, and being used as a means for deducing the reasons for such, it forms a very useful reminder of what work should be done at what time. Nobody's memory is infallible, and indeed, such important operations as the sowing and planting of seeds at the proper time should not be trusted to the memory. By experiment the gardener finds out at what time it is best to do certain things in his district, but when once he has found them he ought to record them, for they are easily forgotten.

There are two features which should not be omitted from the Garden Diary, and these are pages for Items of Interest and pages for Notes on Plants. The gardener often reads in the papers little tips which may be very useful to him. These should be jotted down in the Garden Diary and looked through occasionally. This tends to make the gardening more successful. About the Notes on Plants, the gardener very often will see a plant he would like to grow, in some friend's garden. If he takes down its name, height, colour, and period of flowering in his Garden Diary, he will be able to get that plant at a nursery in the autumn.

Indexing.—This appears to be the only difficulty in the keeping of a satisfactory Garden Diary, but it is essential, since without an Index nothing can be found easily. We consider the best plan is first of all to page the book, and reserve a twentieth part of its total number of pages for Index at the end. Cut these and mark them A B C and so on, on the edges, as is done in the case of "Where is it?" books, and construct your Index as you go along. If your diary is in 4to. pages (and this is most desirable), each page will carry two columns of Index. When you write up your diary and put dates of sowing artichokes, put the word "Artichoke" and its page number

under "A" in your Index. Likewise, when you write Notes of Interest or Notes on Plants, put the headings down in your Index as you go along. If this is done the work is simple, but if a diary has to be indexed at the end of the year, the task is a mammoth one.—E. T. E.

GARDEN EDGINGS.

Hundreds of gardens are utterly spoilt owing to the supreme ugliness of the edgings used for separating the borders from the pathways. And it is time indeed that a protest was made against some of the more striking productions known as "Edging Tiles." Three of the worst of these types are pictured at Figs. 1–3, and it is an astonishment to us that anyone artistic or inartistic can tolerate them as an edging to flower borders for a minute. Ugly, highly-coloured slabs of earthenware they frequently are, suitable enough for foreign gardens, but entirely out of place in homely English gardens where true beauty of form and flower should be the first considerations.

Fig. 1.

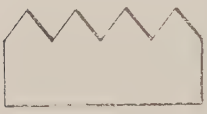

Fig. 2.

Fig. 3.

The edging for the garden should be as plain and as unobtrusive as possible. This can be managed by using the plain stone slab shown at Fig. 4. This is about 1 ft. deep and about 15 ins. in length. The slabs can easily be obtained in most districts, for they are abundant in many beds of "laminated" sandstone or limestone.

Fig. 4.

If the borders are made to be absolutely permanent features of the garden, the question of putting down the edgings in a permanent manner becomes imperative. Edging stones of the kind just described are apt to sink, and it is then a difficult matter to raise them satisfactorily. If, however, the border is only temporary and further alterations contemplated in three or four years' time, it is quite sufficient to beat the soil in the edging trench firmly and set them in this, ramming material as hard as possible on both sides of them.

Permanent edgings must be laid differently. Fig. 5 shows the best way of laying them. A trench is got out and two lines of bricks laid down along it, as represented by AA and BB. These lines are left 3 ins. apart. The cavity between them is filled up with concrete, and should the soil not be solid the bricks themselves should be laid on a 3-inch bed of concrete. The edging stone is then inserted between the top two bricks, and made firm with cement.

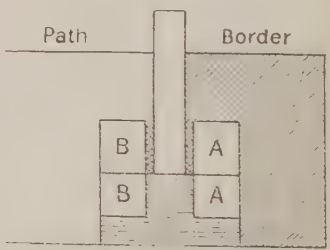

Fig. 5.

An alternative method is shown at Fig. 6. A trench is got out, as before, and a 3-inch bed of concrete laid down. Before this has com-

pletely hardened, the edging stones are put in and set in more concrete.

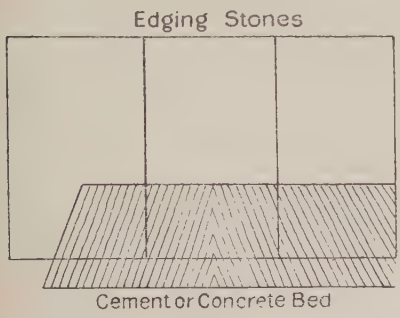

FIG. 6.

The soil on both sides is beaten as hard as possible.

Where the family are fond of dwarf rock garden plants as edgings to the perennial border, no trimmed stone should be used to separate this from the path. Instead, roughly shaped boulders and irregular rockwork stone should be used, as is pictured in Fig. 7, for the border

set in concrete if they are sufficiently large and heavy. Edging stones of any kind should never protrude more than 4–5 ins. out of the path or border. If they do they give the garden an appearance too ugly to be described. See also the article on *GARDEN PATHS*. For the plants to use for edging, see the article on *EDGING: HARDY PLANTS FOR*.—E.

GARDEN ENEMIES.

By garden enemies we mean what are generally known as the animal enemies of the gardener. Another contributor is dealing with garden pests, namely, with the insect side of the subject.

Probably the enemies of first importance to the gardener are:—

Stray Cats and Dogs.—These, as is well known, can spoil a beautiful border in half an hour by tearing it up or rolling on it. There are one or two well-known methods of

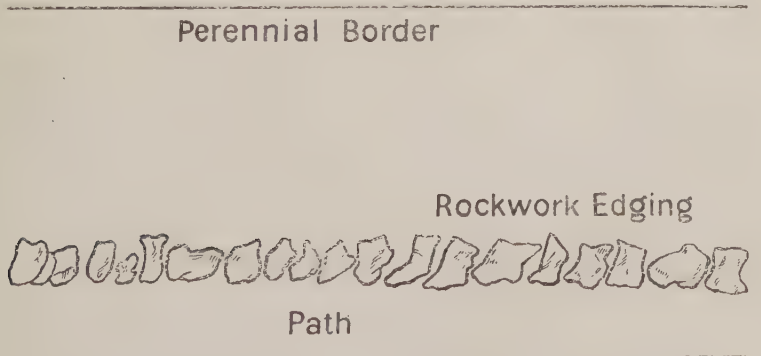

FIG. 7.

side, and a plain edging to separate the other side of the path from the rose garden. The plants can trail over the "Rock Edging" as it is called, and make the border look most beautifully natural. In this case the stones will not need to be

dealing with them which must be mentioned. The first of them is to half-cut some tempting pieces of meat and put a big dash of cayenne pepper in them, leaving these pieces about the borders where the creatures come. They soon learn

a lesson not to visit the garden again, after tasting one of these titbits. One of our esteemed friends tells us that he sinks bottles in his borders and puts a little strong ammonia into them. One good sniff is enough to send these animals bounding over into the next garden ! It is not legal in most districts to put poison down, but if the animals can be caught and chastised, they will probably return to their own masters and mistresses in a different frame of mind.

Mice.—These are often very troublesome, both in the garden and in the gardener's storehouse. The wood and spring metal traps are the best means of catching them, and after they have been in use they should be scalded and scrubbed, or they will cease to be effective. The traps should be put about the borders and amongst the foliage, as well as on the potting-shed floor. They should be examined daily.

Moles. —These pests are terribly troublesome in the garden. We have seen glorious gardens on light, sandy land completely spoilt by moles burrowing in them and casting up mounds. It is little use setting mole traps in the smaller runs made by these pests, for the chances are ten against one that not a single mole will be caught. In the case of the main runs the matter is very different. Provided that the traps are set firmly and well concealed, also as long as they are not touched with the naked hands, there is no reason at all why a mole a day should not be caught. A better plan still is to follow the main runs to the "earth," and dig this out and destroy the pests. Poisoned worms are not much good.

Rats.—These are great pests, though, fortunately, not over-abundant. Rat poison is good, but must be of a kind which is harmless to human beings and other animals, otherwise in most districts the authorities will not allow it to be put down. The big wire rat-traps are effective but unsightly, and should only be used in the worst cases.

Garden Robbers may also be considered the direst garden enemies, but as they are a different kind of enemy to any of those named above, they are treated of in a separate article of that name.—E. T. E.

GARDEN ENGINE.—See under WATER BARROWS in *GARDEN APPLIANCES*.

GARDEN EXPERIMENTS.

In a recently published book[1] the writer spoke briefly on the subject of "Experiment in Gardening" in one of the concluding chapters, and as it seems that the Dictionary would be incomplete without a little essay on this subject, he takes up his pen to write again on a topic in which he has always had great interest.

British gardeners as a general rule seem terribly afraid of experimenting. Some of them undoubtedly think it is pure waste of time, but for the most part it is simply ignorance of its great and frequently profound value which keeps them from the work. This is not the case with gardeners in France or in many other countries ; most gardeners of other nations are very quick to realise the great value of experiments, and make them accordingly. In England, alas, we depend on the Royal Horticultural Society, and on other similar organisations, for carrying on this work ; they are already overburdened with it, and many promising side-lines have to be left un-

[1] *Jottings of a Gentleman Gardener.*

investigated or the work would never end. This state of things would never arise if British gardeners would carry out experiments for themselves, instead of putting them on to the organisations just referred to.

British gardeners have got the reputation of being behindhand in respect of experimental work, and this reputation, though well deserved, is not a pleasing one. It will, of course, take some years to live down, but the sooner British gardeners wake up and realise the need for, and the intense value of experimental work, then the sooner this ugly reputation will disappear.

There are plenty of subjects awaiting the experimenter. There are, for example, diseases for which there is no real cure known, as in the case of Wart Disease of Potatoes. If a number of practical gardeners would give attention to this matter, a cure would probably be found during the next few years, whereas it might take a single experimenter at one of the gardening colleges, for instance, a much longer period to solve the problem, for he would be working alone. The comparing of notes is of great importance, and this is best done in the correspondence columns of gardening papers.

Besides trying to obtain cures for diseases by experimenting with various mixtures or chemicals, there are plenty of other fields for this work. We shall see one point in this connection in the article on *Iron and Iron Compounds*. There are scores of chemicals which must have value as fertilisers or fungicides, if it was only known, and the way to find out is, of course, to try them by experiment.

Many things of great value have been discovered by experiment. Certainly the value of sulphate of iron was found out this way, and so also was the value of carbonate of soda (washing soda), as a fertiliser for growing good onions. People saw the chemicals and tried them; they found they were good. It is for us to do similarly with other chemicals and see what they are worth.

It may be said that such experiments often involve great risk. If some poisonous compound be hit upon during the research, the plants may be killed.

That is true, of course, but it seems a cowardly thing to do to omit experimenting because there is a little risk. Foreign gardeners take risks; they do not fear them, so why should we?

A perfect plant-food for each of the five different kinds of soil recognised by gardeners remains yet to be discovered. It will probably need hundreds of experiments to solve this problem in a satisfactory manner. Again gardeners can help. If a single thousand out of the hundreds of thousands of gardeners there are in England would do one careful experiment on this point, and contribute details of their experiments to the gardening papers, we should probably have the answer to the problem within two years' time instead of having to wait the two hundred years which one prominent private experimenter has predicted will be needed. Is not this worth trying for? Would it not be a blessing? Our catalogues could then be cleared of all the patent fertilisers they now advertise, many of which are of such poor value.

Many other important matters open for and awaiting experiment might be mentioned, but we must say a word or two on the subject of

How to Make Experiments.—Mr Fred Chittenden, V.M.H., the director of the Royal Horticultural Society's Garden and Experimental Station at Wisley, a man who has probably conducted and superintended more experiments than any other man now living in this country, told us the secret of carrying out successful experiments in a word or two. He said that the secret was "to have two or, if possible, many more plots, the condition and nature of which was identical except for the particular dressing to be tried."

Thus if a reliable experiment is to be tried we will say, for instance, with potassium pyrophosphate—a chemical the value of which as a fertiliser nothing, we believe, is known,—two plots at least, the soil of which is in an identically equal state as regards nature, condition, and fertility, are selected. The plants are set out on the same day, by the same person, at the same time, at the same distance apart, and the same number of plants set on each plot. They are given the same amount of water, at the same time, by the same person. Their cultural treatment is precisely the same. The crop is gathered on the same day, by the same person, at the same time, and weighed on the same day, at the same time; and, in a word, everything is done in the same way, by the same person, at the same time, to the plots, with the exception that one of them is dressed with potassium pyrophosphate and the other is not.

To get very accurate results the land should have all been treated in the same manner for the last six or seven years, or if that is not possible, the experiments should be conducted on plots freshly dug out of grass land in order that there can be absolutely no loop-hole or different conditions. This is the way experiments should be done,—the only safe way,—the only way of being certain of getting accurate results.

When experiments are done with spraying liquids,—insecticides or fungicides,—great care should be taken not to let any of the liquid be blown on to the plot or plots supposed to be left without a dressing. As it is frequently impossible to avoid this in the ordinary way of working, precautionary steps must be taken. At any rate the plots should be 4 ft. from each other; and if the liquid must be applied during windy weather, direct the nozzle of the machine in the opposite direction to the way the wind is blowing. Where, however, the experiment is very delicate, and it is of vital importance to omit getting any single trace of the liquid on the control plots, some arrangement such as a screen or a temporary wall should be put up, and then there is no chance of the liquid straying.

It is, of course, of extreme importance to make detailed memoranda of observations gained from both the treated plot and the control plot from the very day on which the experiment was started. In this connection nothing should be considered too trifling to set down. Trivialities—as they appear to be—may be the kernel of the problem. We need not press this beyond this point.

Many other practical points might be described in detail. But in our present limit of space we must confine ourselves to what appears above. If any gardening author should perchance to read these lines with more care than other people, we might say that a simple book on "How to Experiment

in the Garden" is very badly wanted. Perhaps he will oblige us by writing it,—we hope so anyway. There will be no difficulty to find a means of distributing it to gardeners.—E. T. E.

GARDEN FENCES.

A garden, large or small, is incomplete without a fence of some kind. In providing fences for the various phases of the garden, for utility and appearance, special circumstances have to be taken into account. For a kitchen garden there is no fence equal to a wall, be it brick, stone, or a composition.

Not only is this more substantial than any fence could be, but it is so useful for the cultivation of fruits and choice climbing plants.

It would be difficult to suggest any particular subject to make a fence for any special site, as circumstances on the spot must determine the best type to be employed; suffice it must to name some of the many subjects adaptable for this purpose.

Deciduous Subjects.—Of these, none can compare to the white Hawthorn, commonly known as Quicks. These not only provide good shelter, but also a guard against cattle of all kinds without any danger to the animals, as in the case of yew for example. A Quick fence can be grown to any height, and can easily be kept in good condition if the foundation is properly laid. By two annual cuttings an established fence can be kept very neat, and quite impervious to cattle. It is a moot point whether the Quicks should be planted singly or in a double row. Both methods produce a good fence if the plants are cut hard back the same season of planting, and not allowed to run up too quickly afterwards. Bear in mind if height is quickly obtained it will generally be at the expense of a thin base, and when once this error is made it is difficult to correct it, except by drastically cutting down the fence to within 1 ft. of the base; whereas if the foundation is properly laid there is no need for that. For a single row of plants three to 1 ft. should be allowed. For a double row 10 ins. between the rows, and also between the plants, should be the distance apart.

Deeply dug, well-manured soil, weed-free ground for some years afterwards is important, since the shrubs cannot progress properly when the soil is robbed of its food, and the roots almost choked by weeds.

Beech and Hornbeam make a capital fence where cattle are not allowed, as they are apt to eat the young shoots in spring, which naturally does harm to the fence.

Myrobalan Plum is in places much employed for its quick growth, but such fences are not so closely grown.

Living Fences.—These can be plentifully provided; the quickest growing subject is *Cupressus macrocarpa*, but it is subject to suddenly dying in places, and if not properly pruned, the plants are liable to blow over. Where, however, an extra quick growing subject is required, this subject is desirable.

For a fence 10–20 ft. high *Thuya Lobbi* is probably better than anything else. Its growth is so rigid, and does not occupy more than a yard width at 20 ft. high. For sheltering an orchard this is the subject to plant, but not near the sea where the site is windswept; stout plants 3 ft. high, put in 1 yd. apart, quickly adapt themselves to the site.

English Yew provides a neat fence, high or low, of any width. It requires very little attention when

established beyond once clipping during the year, and August is the best month for this operation. [On account, however, of its leaves being poisonous, it must never be planted within the reach of animals.—EDITOR.]

The most serviceable evergreen fence of all is the common Holly (*Ilex Aquifolium*), and it is quite impervious to cattle, absolutely wind-proof, and gives little trouble beyond needing an annual clipping. The first week in April is the best time to plant.

Another cheap, quick growing fence plant is found in Evergreen Privet (*Ligustrum vulgare*). This gives good shelter, and is neat though not attractive beyond its deep green leaves.

Common Laurels (*Laurus rotundifolium caucasica* and *colchica*) also make capital fences or screens, which are neat and serviceable. The plants grow rapidly and are easily managed. One cutting with sécateurs is sufficient; this gives the fence a more natural appearance than when the ordinary garden shears are employed, which invariably cut the leaves and rob the plants of their natural appearance. The common Euonymus makes a capital fence, especially near the sea.

For some sites coloured fences are desirable, and such may include *Aucuba japonica variegata*, golden Holly, golden Privet, *Retinospora plumosa aurea*, and golden or silver Euonymus.

There are various flowering subjects that can be appropriately employed. *Berberis Darwinii*, with its attractive orange-coloured blossoms, and *Escallonia macrantha*, near the sea, are two of the best subjects imaginable; and so neat in growth. The Tamarisk, too, near the sea, is valuable.

Preparation of Fence Sites.—No matter what subject is employed, its ultimate success is largely governed by the preparation of the site. Where the soil is light in character, preparation is simple; deep digging and manure will quickly produce a desirable fence. Where the soil is stiff, with a stiffer subsoil, especially if very wet, much more preparation is then required. Without due regard to this foundation success cannot be achieved, or at least it is much hindered. All sites a yard wide in such soil should be trenched at least 2 ft. deep, an ample supply of manure being incorporated in the first spit of soil to encourage free root action, which means extended branch growth. The plants growing in trenched soil do not suffer nearly so much in dry weather as those in stiff, impervious soil: the trenching conserves the moisture.

Early autumn planting generally succeeds better than at any other period, except for some few evergreen subjects which are best put in in early April.

Artificial Fences can at times be advantageously employed. For instance, if a herbaceous or rose border is arranged in the centre of the garden on each side of a grass path, some screen is required to give effect to the border and shut out the view of the vegetables behind. For such a site rustic larch poles 10 ft. high, with the side spurs 8 ins. long, if left on the poles, provide an attractive fence, and a good support for rambling roses. A yard apart is close enough for the poles. They are easily fixed in the soil by the aid of an iron bar, and if not less than 4 ins. in diameter at the base, they last a long time and are easily replaced. Rustic oak or ash branches answer the same purpose.

For a low, wind-proof fence to shelter vegetables or flowers in frames or in narrow borders, a good contrivance can be made with evergreen branches, such as spruce and Scotch or Austrian pines. Stout stakes are driven into the ground on each side of the fence 2 ft. or so apart, the fence being made not less than 1 ft. wide and of the height desired. Between the stakes lay the branches neatly and securely, making them fast at the top with a strand of wire. Where rats are troublesome, close-meshed wire should be fastened to the fence on either side, or the rats will quickly spoil its appearance, and become a nuisance also. If the wire netting is fixed firmly in the soil on each side, the branches can more easily be arranged. Hedge trimmings, especially evergreen subjects, can be utilised for such fences.

Temporary shelters for seedling vegetables can be made easily with wire netting and straw packed between about 1 ft. thick, but these, naturally, will not last long; such structures may serve a useful purpose in the raising of seedling flowers or vegetables.—E. M.

[It should be noted that the names of the subjects suitable for fences are those by which they are generally known, and do not necessarily correspond with the new nomenclature adopted at Kew.—EDITOR.]

GARDEN FOES.—See *GARDEN ENEMIES, GARDEN ROBBERS,* and *INSECT PESTS.*

GARDEN FOLIAGE PLANTS.— See *FOLIAGE PLANTS FOR ALL PURPOSES.*

GARDEN FRAMES.

No garden large or small, not even excepting the cottage garden and allotment, should be without at least one frame. It is of immense value in connection with the greenhouse, the vegetable garden, the flower garden, and, to a more limited extent, for fruit.

There are several types to suit different conveniences. For practical purposes we may class them thus—the heated pit, the hotbed frame, the cold frame, and the skeleton frame. Then there are different shapes such as the double span, and the single span, the latter form being decidedly the more general and, all things considered, the more useful.

The Heated Pit is usually built of bricks, the bottom being below the level of the surrounding ground. A single row of 3-inch piping along back and front, heated with hot water, will supply a steady heat for the vast majority of purposes to which it is likely to be put. In a pit of this description there is also the opportunity of partly filling the frame with leaves and stable litter, thus adding to the heat.

The Hotbed Frame. — This is usually a one- or two-light wooden frame, sometimes with span lights. It is put on the top of a bed of manure and used for raising half-hardy flowers and early vegetables. See article on *HOTBEDS.*

The Cold Frame or Pit.—If a portable frame be used for this purpose, it should be set in a position where it will get the fullest amount of sunshine and preferably on a hard, dry bottom. If it is to be used for pot plants or plants in boxes, there should be a layer of coal ashes or shingle at the bottom to a depth of at least 2 ins. If seeds are to be sown, seedlings pricked off, or cuttings inserted directly into the frame, it will be necessary to make up a bed of soil. This may be done by spreading a layer of leaves over the bottom

and covering this with at least 4 ins. of sandy soil and leaf-soil passed through a ½-inch sieve. In all cases the soil should be made firm, especially around the sides; and after this has been done and the surface levelled, a thin layer of sharp sand should be spread over the surface.

The Skeleton Frame is simply an open arrangement of wood so arranged as to support mats or the lights or sashes from other frames. A sheltered though not shaded position should be chosen for this, and a hard, dry level bottom surfaced with 2 ins. of ashes. A similar arrangement might be erected over a plot of ground set apart for pricking off seedlings. It is used simply as providing slight protection during severe weather. Additional protection may be given by tacking canvas around the sides.

The VEGETABLE GARDEN may benefit considerably by using the frames for forwarding plants during the early months of the year, and planting them in the outside garden (after gradually but thoroughly hardening them in the skeleton frame) in late March, April, and early May. The following subjects are amenable to this treatment: Beans (broad, dwarf, haricot, and runners), Broccoli, Brussels Sprouts, Cabbages, Cauliflower, Celeriac, Celery, Cucumbers, Globe Beet, Leeks, Lettuces, Marrows, Onions, Peas, and Tomatoes. These should be sown preferably in a heated frame or, failing that, in a cold frame several weeks before they would be sown in the usual way outside.

Forced vegetables may also be procured by means of heated frames of such subjects as Asparagus, Beans (French and haricot), Carrots (Short Horn), Cauliflowers, Cucumbers, Endive, Globe Beet, Lettuces, Marrows, Melons, Mint, Mustard and Cress, Peas, Potatoes, Radishes, Rhubarb, Seakale, Spinach, Tomatoes, and Turnips. A commencement may be made in late autumn and continued until the produce is available from outside sowings.

The FLOWER GARDEN may benefit from the use of frames by the propagation of all kinds of half-hardy subjects, such as Ageratum, Alyssum, Alternanthera, Calceolaria, Fuchsia, Heliotrope, Lobelia, Marguerite, Pelargonium (Geranium), Pentstemon, Viola, and similar well-known bedding plants. Practically all kinds of rock plants may be propagated from cuttings in a cold frame in the summer months. Frames may also be used for the sowing, pricking off, and hardening of Alyssum, Antirrhinum, Asters, Clarkia, Lavatera, Petunia, Stock, Verbena, Zinnia, and practically every hardy or half-hardy annual which will bear transplanting.

Carnations, Dahlias, Early-flowering Chrysanthemums, *Lobelia cardinalis*, Phloxes (herbaceous), Roses, Salvias, Shrubs, and Sweet Peas may also be propagated in frames.

The GREENHOUSE will benefit largely and in innumerable ways from the use of frames for purposes of propagation by means of seeds, cuttings, and layers, for giving cool condition during the summer and ample protection in the early months of autumn. A list only of greenhouse plants which spend part of their career in a heated or cold frame would more than fill our available space. A frame built against the low wall of the greenhouse proves a great blessing for such purposes.

The essentials of a good frame are that it be rain-proof, the glass being firmly bedded in putty. The wood should be coated with three coats of good white lead paint, especially

where it rests on the ground. [Green can be used for the outer portions except the lights.—EDITOR.] If the frame be portable it should not be too large. For a two-light frame, 8 × 6 ft. should be the maximum size.

SHADING for a frame may be provided by covering it with canvas, tiffany, or mats, or if a permanent shading is preferred, a cheap mixture is lime made thin with sour milk or buttermilk. This may be painted over the glass, and can easily be washed off with hot soapy water.

VENTILATION may be provided by using small blocks of wood cut into steps, so that more or less air may be admitted as desired. This is by far the most convenient method, though bricks or stones may equally serve the purpose.

PROTECTION FROM FROST is best provided for by means of Archangel mats augmented during severe frost by a layer of litter, straw, hay, or bracken. The sides may be protected by banking soil, ashes, or heating material against them, keeping it in place with boards or wattle hurdles.—W. F. R.

GARDEN FRIENDS. — See *INSECT FRIENDS.*

GARDEN FURNITURE.

It would appear that the beauty of the garden has at all periods been enhanced, and its pleasures increased, by the addition of "furniture." Old gardens show traces of the use of portable furniture, but oftener still they contain the remains of the solid and permanent character of the arbours, summer-houses, rustic seats, and stone or lead figures once so prominent in old English gardens. To-day the furniture is of a less substantial character; it is, however, none the less useful, and adds to the beauty of the garden or lawn upon which it is shown.

Reminding readers of the more important furniture suitable for use in the garden, the chief divisions are as follows :—

Chairs and Awnings.—Large seats, usually 6 ft. long, are used in parks and conveniently distributed in large gardens. Iron ends and frames, frequently painted, are the best, the laths should be of wood, painted green or grained; if of oak or pitch pine, they must be well varnished. Single and double seats, with or without arms, are also made in a similar way. Those in general use are folding, and are easily carried about. Lounge chairs, covered with striped canvas, the larger ones preferably with awnings, are useful. Among other varieties are folding cane garden or deck chairs, so-called lawn or beach rests, and folding stools. (See also paragraph on SEATS.)

Flower Stands.— There are many places where fixed or portable wooden flower stands can be erected; painted green, and furnished with a plentiful array of plants in bloom, such stands are an attractive feature in the garden. Wire stands are useful in conservatories, and some of the portable types are suitable for the garden also. In the form of baskets too, wire work is a nice addition to the garden, and makes suitable receptacles for hanging plants, etc. (See article on *BASKET PLANTS.*)

Folding Furniture.— Folding chairs (to which reference has already been made) may be supplemented by tables, lawn settees, and camp furniture. Folding tables are easily erected on the lawn, and can be readily removed; the frames should in all cases be of hard wood, and, preferably, polished self-colour.

Footstools.— In damp weather a supply of footstools is invaluable; they should be made of laths on short legs raising them well out of reach of the damp grass.

Hammocks.—There are many types of hammocks which can be slung from trees or supported by specially made folding legs or sticks; the ideal hammock has an awning over it, and is furnished with comfortable cushions. As in so many other garden furnishings colour adds to the beauty and attractiveness of the hammock. The best position for a hammock is in a shady spot in full view of gay flower borders.

Leaden Figures.—Leaden and stone figures were among the garden ornaments of olden times, and modern replicas of old styles are favourite adornments of the garden planned on antique lines.

Rustic Furniture.—Rustic seats, and ornamental arches and trellis, are described in other articles; they may be supplemented by chairs, seats, small tables, and numerous furnishings in this very attractive style—one in which the amateur can score.

Seats.—The permanent seat of wood and stone is an excellent architectural addition to the garden. Such seats can be constructed round large trees, in suitable corners, or cut into a hedge, shrubs and evergreens being trained to form overhanging canopies. The surroundings of garden seats should be in harmony, and good garden work in conjunction added to secure restful seclusion. Some seats may well be in full view of colour borders and pleasure grounds, while others may be hidden away in arbours for those who want rest and quiet talks.

Summer-houses. — The summer-house is, of course, structurally a work of greater magnitude than the mere arbour or seat contrived in wall or fence. Many summer-houses are large and roomy, and require a certain amount of furnishings—seats, tables, and the like. Care should be taken in selecting a suitable location, which ought not to be too much exposed to the sun in summer or to the east winds in winter. Their decoration, including coloured glass and blinds, should not clash with the surrounding foliage or blooms. (See also article on *Garden Summer-house.*)

Sundials.—The old sundial is a relic of days gone by; it is, however, one that is clung to as being an ornament, and a reminder of the old English garden in which it once was considered a necessary feature. Many modern replicas of old dials with their quaint mottoes are now made, and their instalment in a garden modelled upon old-fashioned lines is a desirable addition.

Tables.—The tea-table is a necessary fitment in a modern garden, and a small work table is useful in a summer-house. There are round, oblong, and fancifully shaped tables of wood available, and some with ornamental iron frames; others are made in rustic wood, and many charming little drawing-room tea-tables are equally suitable for garden use.

Tents.—Garden tents vary from the small shelters from sun or rain to marquees accommodating large numbers of people. Lawn Tents with woodwork painted green, and covered in with striped canvas, with extensions, are made in several stock sizes. There are also Tennis Tents with open fronts erected on jointed poles, with brass mountings and complete with adjustable centre tables; and Umbrella Tents and Bell Tents in endless variety, all adding to the delights of garden or park.

Vases.—Vases mounted on pedestals, replicas of ancient Greek types, were formerly made chiefly of lead, but latterly of terra-cotta or other less costly materials. When filled with flowering plants they are pleasing additions.

Wicker Work.—Garden furniture of every description is made up in wicker work, and furniture of this kind is probably the most welcome. It is light, portable, and inexpensive, and, when duly cared for, lasts many years in garden or summer-house.

F. W. B.

GARDEN GATES.

Gates for dividing portions of the garden, used in connection with trellis and other fencing, may be made of similar materials. Such work can be performed by an amateur—indeed the gardener or amateur carpenter is generally more successful in making appropriate gates and fences from a rural standpoint than the professional workman.

Solid wooden gates, unless used in conjunction with a close-paled fence, should be avoided. Light frames of wood, with feather-edged pales placed a few inches apart, look very well, and the upper portion can, if desired, be raised by a light trellis of laths, either in square form or diamond-shaped to correspond with an adjoining fence. Rustic fencing is much favoured, and gates to correspond can be made quite easily. In some instances where bamboo trellis is used, gates of the same material answer very well, in which case all the joints should be firmly wired and screwed. When the gate is at the end of a path it should, of course, be the same width

as the path, although when an entrance to some other portion of the garden is needed in a continuous fencing on the lawn or approached by a narrow side path, it can be made wide enough for the purpose for which it is required. It is advisable to remember that the gardener may want to use the gate for his lawn-mower, roller, or water-barrow, and any knocking of the posts or gates should be avoided.

There are several points to observe when hanging gates, the most important being the strength and rigidity of the posts, which last, according to the weight and size of the gates, should be sunk deep into the soil, that portion below ground being well tarred. If the soil is light, some stones and a little cement or concrete should be well rammed round the stumps, which some say should be placed upon half a brick to prevent sinking. The posts must be perfectly upright, and the gates hung preferably with hooks and bands, and fitted with a good catch. A very slight tilt might with advantage be given to cause the gate to close naturally, but if it is important that it should close tightly a spring must be added.

The size of the garden gate is, of course, governed by circumstances and surroundings; a gate giving entrance to the garden from the yard or street ought to be at least 4 ft. wide; a smaller gate leading from one part of the garden to another may be smaller, preferably about a yard—a good width for a path.

Gates should be painted or stained to match the fences. If painted, "garden green" is most appropriate, but if a gate is inserted in a privet fence, or in conjunction with iron or wire fencing, stained and varnished oak is recommended.

Iron gates must be made by a smith, or they can be purchased ready for attachment with bolts and nuts to wood posts or continuous iron fencing. Frequent painting of these in industrial districts is essential, otherwise they will be quickly rusted and ruined.—F. W. B.

GARDEN GEOLOGY.

The thickness of the soil and rocks with which the gardener is concerned is insignificant as compared with that of the underlying strata. The soil may be made more or less independent of the mass beneath in so far that its mechanical and chemical constitution can be varied by the addition of manures and by drainage. It is, however, distinctly related to the substratum; in many cases the soil has been derived directly therefrom, and is dependent on it for its supplies of moisture. For this reason, then, in estimating the suitability of ground for horticultural purposes, we have to consider, as regards the substrata, certain factors that are the least likely to change, and that are, consequently, the most worthy of attention.

The layers of deposits at the earth's surface are acted upon continuously and in varying degree by meteoric agencies (frost, heat, rain, etc.), with the result that a subsoil and a soil are formed. (For an account of the manner in which these are produced, see article on *SOILS: THEIR ORIGIN AND NATURE.*) The soils that cover the surface vary in nature from light sands, through loams, to stiff clays; but their boundaries are not so sharply defined as those of the subsoils and the strata beneath them. It is within the province of geology to determine the nature and extent of the beds that come to the surface in all parts of the country. A geological survey of a district, moreover, includes details of the arrangements of these beds, and determines whether they are tilted or folded or broken by faults; and in addition, notes their mineral character. Results of such surveys are recorded on maps, of which the great advantage is that all the features of any area can be reviewed at once. Moreover, as they are published officially and on uniform scales, they afford a trustworthy basis for investigation, and so save much individual labour.

Drift Geology.—The arrangement of the beds, to which we have just alluded, constitutes what is known as the *solid* geology of a district, and maps recording their features are called "solid" maps. There is, however, an important series of superficial deposits which owe their origin to processes that took place comparatively late in the history of the earth. Such are the gravels brought down by rivers, and boulder clays resulting from glacial action, included under the general name of *Drift*. These deposits, masking the underlying solid rocks, often cover extensive areas; the maps that represent them are accordingly termed *Drift Maps*. *Drift Geology* is, therefore, of the first importance to the horticulturist, for in no country have the actual soils been mapped. At best, a Drift map is to be regarded as a subsoil map, and in the case of "sedentary" soils necessarily affords direct indication as to their nature. In other cases it can, with careful interpretation, give much useful information as to subsoil, water, and drainage. The details of topography included in the Drift map must be taken into account in judging the character of soils, for the configuration of the ground is intimately related to geological structure. Thus, hard rock-bands tend to stand out prominently on the surface, and the softer beds to be worn away to lower levels. The soil on hard beds is almost always thin, partly because it is dispersed to lower levels and accumulates at the bottom of slopes. Over large areas of generally uniform level, such as tracts of alluvium and plateau country, the soils are, as a rule, of a "sedentary" nature. In general terms, the formation of a soil in a given area depends on the relationship between weathering and transport.

Permeable and Impermeable Beds.—It is not necessary to consider in detail the mineral character of all the prevailing rock-masses. Although numerous varieties of both crystalline rocks and stratified formations may be recognised, the soils to which they give rise are few in number, and the rocks themselves, for our purpose, need to be considered simply as permeable or impermeable. Soils resting on sand, gravel, chalk, or other permeable beds are warm and well drained, while those resting on clay, marl, brick "bind," or other impervious material are cold, and apt to be water-logged. Moreover, formations distinct geologically may give rise to soils almost identical; on the other hand, sedentary soils originating in the same formation may alternate between sand and clay, or may be calcareous in one part and non-calcareous in another. The geological status of a formation is, therefore, of far less importance than its mineralogical character. But, however rich a soil may be in plant-food, it will be rendered useless by a superabundance or lack of water. Since the fertility of a soil obviously depends largely on water-supply, geology is of prime importance as yielding information concerning the beds that underlie the soil, and their respective value as water-bearers.

Kinds of Rocks.—We will now review briefly the salient features of rocks and their arrangement. The term "rock" in geology is used for all constituent masses of the earth's crust, whether hard or soft, loose or compact; and includes, therefore, limestones, clay, gravel, sandstone, and sand, as well as the crystalline rocks made up of aggregates of minerals, *e.g.* gneiss or granite. Three broad divisions of rocks are recognised: the *stratified* or *sedimentary* rocks, *i.e.* those laid down by water and wind; the *igneous* or crystalline; and the *metamorphic*, those that have been re-formed by the agencies of heat and pressure. The igneous rocks have welled up in a molten state from the deeper portions of the earth's crust, sometimes filling fissures in the rocks that they have invaded. Heat, moisture, and gases proceeding from them have altered adjacent rocks, and the effects of these, subsequently enhanced by the pressure attending the crustal movements of the earth, have caused the formation of metamorphic rocks.

By far the greater part of the surface of this country is occupied by the stratified or sedimentary rocks. These were originally deposited in layers, one above another, but where, as commonly, their approximately horizontal position has not been maintained, they are tilted or arched, or folded in basin-shaped structures. Often, owing to surface wear and tear, only the upturned edges of the beds are exposed. In some places the rocks constituting hill-tops form "outliers," *i.e.* surface erosion has cut them off from main masses some dis-

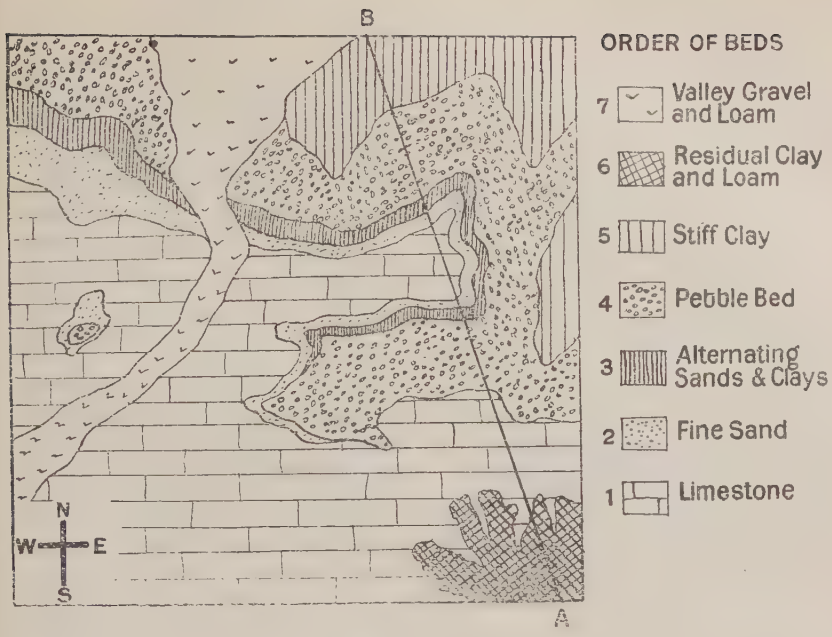

FIG. 1.

EXPLANATION OF MAP.

Underlying the whole area, and coming to the surface in the south, is a thick limestone, which slopes or dips towards the north. This is overlain in the northern part of the area by a thin bed of fine sand, above which is a series of clays and sandy beds. Above these is a thick pebble bed, which extends over their edges on the south, and rests eventually on bare limestone (see section). In the north-eastern part of the area this is overlain by a stiff clay. The surface of the south-eastern part is occupied by a residual clay (formed by the dissolution of the limestone) which contains stony fragments of other beds. On high ground towards the west is an " outlier " —a patch isolated from the main mass ; and extending north and south is a tract of valley gravel and loam left by a stream that formerly flowed through the country. The relations of the beds are represented on the diagrammatic section along the line A–B. (See Fig. 2.)

Springs are thrown out along the line of the lower clayey beds (3), but on the south side of the pebble bed (4) the water soaks directly into the limestone, leaving the surface dry. The water falling on the pebble bed sinks through and leaves a stony surface of barren ground. The limestone is porous and dry, its soil being a thin, friable loam. The overlying sand (2) forms a thin, light, and productive soil, loamy in parts. Around the high-lying outlier the soil is sandy and dry. The upper clay (5) forms rolling ground, with a thin, cold, limeless clayey subsoil. Rich, moist, loamy soil is found on the tract of the valley gravel. A thin capping of stony clay and loam marks the area of the residual clay, and forms a sharp contrast with the surrounding limestone.

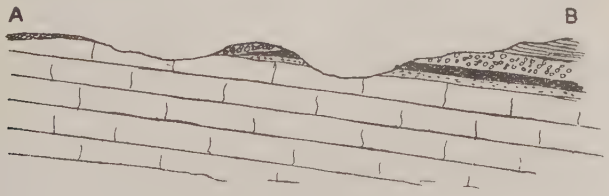

FIG. 2.—Section along line A–B.

(The vertical scale is exaggerated.)

tance away; or the removal of the upper portion of an arched series of formations has exposed the older beds within a ring of the newer, thus forming an "inlier."

Water-bearing Rocks.—The arrangement of beds must be considered in its relation to the water-bearing capacity of rocks. The water in rocks is derived originally from rainfall, and the amount that percolates into the ground depends on the texture of the soil, and the disposition of the underlying geological formations. Loosely aggregated beds, *e.g.* sands and gravels, absorb a large quantity, while the more or less impervious beds throw it off the surface, whence it flows to join streams and rivers. The absorbed surface-water sinks until it reaches an impervious stratum, or arrives at the level of underground saturation (the water-line). The inclination of an impervious stratum

FIG. 3.

1. Superficial gravel. 2. Sands. 3. Stiff clay. 4. Coarse pebbles. 5. Sandstone. 6. Soft limestone. 7. Marl. 8. Sand. 9. Clay. 10. Sandstone. Water-table indicated by - - - - - - - - -. Springs are thrown out at the places marked × ×. On bed 1 is a "perched" water-table.—C. P. C.

often results in water being thrown out at a lower level in the form of springs. Thus a thin parting of clay, marl, or other only slightly penetrable rock may have a marked effect upon the distribution of moisture, and it must be carefully borne in mind that these partings are often irregular or discontinuous, and may be intercalated in beds of generally pervious rock; thus a thin layer of marl may be found to run through a great thickness of chalk, and layers of clay through Tertiary sands. Places where such an arrangement of beds obtains are usually marked by distinct types of natural vegetation.

The application of the general principles of geology even on a small scale can be of great assistance in the laying out of a piece of ground. As an illustration we will consider the area represented on the accompanying map (p. 399).

Choice of Sites.—We can now discuss in a general way the requirements of gardens in their relationship to geological features as read from a map, or as ascertained from actual observation. Probably the least desirable sites of all (except perhaps for the rose garden) are those where clay uncovered by superficial deposits such as brick-earth or gravel comes close to the surface over extensive areas, the soil being wet and cold, and the subsoil very thin. In some cases, however, *e.g.* the Gault vale between the slopes of the Chalk and Greensand of the South of England, the clay often presents a covering of sand and limestone fragments brought down from the higher ground near by, and an effectual system of drainage turns the clay to good account. Thick sandy beds are impoverished for plant growth by water passing through them, but they are improved where they thin out, because, by mixing with fragments of the neighbouring strata, they are provided with the elements that they lack. Consequently, at or near the junction of a sandy stratum with other beds, an increase in the depth and productiveness of the subsoil is usually noticeable, and such a site would be most suitable for the vegetable garden if the family is fond of deep-rooting crops. The subsoil everywhere acts as a regulator of the amount of water contained in the surface layer, that which percolates into it during rainy periods being given up again by capillarity to the surface soil during periods of drought. A subsoil at a suitable level, and containing a fair proportion of loam, offers a good promise of success in kitchen gardening. Where a bed of sandy rock forms the substratum is found the place suitable for a wild garden, and in sites where the rock is exposed a rock garden should be made.

In hot weather porous beds are, as

a rule, moister than clays, and a soft limestone, *e.g.* chalk, is generally sufficiently moist to keep a lawn fresh, although the grass on subsoils above other rocks may suffer. For a fernery a shady place at the junction of permeable with impermeable beds provides an ideal situation.

Superficial Deposits.—We have already alluded to the superficial deposits, and to their great importance in relation to subsoils. Of these, two principal classes may be recognised; the *residual* and the *transported*. The former class are chiefly the result of weathering, and include such beds as high-lying gravels and clays. Such a deposit, for instance, as the clay-with-flints and accompanying loam, resulting from the dissolution of chalk, has a widespread range, and is found to exert a marked influence on the vegetation in contrast with the surrounding porous chalk. The most extensive of the superficial deposits are the valley gravels and loams, the soils of which have benefited in fertility by the thorough mixture of their constituents in transit, and are fairly uniform in depth. Their position causes them to be well supplied with subsoil water, and the loams afford valuable sites for market gardens.

C. P. C.

[A word more may well be said on the matter of water. If the gardener, for instance, wants to make a pond or other ornamental piece of water, he should choose as a site for this not the wide tract of porous limestone so abundant in the central and southern portion of the map, or he will have to put a very thick "puddle" of clay all round and over the base of the proposed pond. The ideal site would be in the stiff clay bed in the north-east and east portion of the map, for here very little puddling would be needed.

Again, if he wished to bore for water, it would be foolish indeed to start boring in the limestone in the south-west corner, for he would have to go very much deeper, until he came on some impervious bed. He should, of course, start his boring anywhere in the pebble bed; if he starts just north of the band of alternating clays or sands before it bends south, he will come to water very soon. Should he start farther north-east in the pebble bed, he may have to go deeper, and if he starts in the stiff clay in the north-east corner, he will have to go through this and through the pebble bed before he comes to water. Water could be easily obtained by boring through the pebble bed in the north-west corner of the map, but it would be waste of time to start in the fine sand below the band of clay on which the pebble bed rests. The natural springs issuing from the base of the alternating bands of clay and sand make such positions ideal for water gardens, and by a little arrangement such springs could be made to drain into the northern portion of the valley gravel to make it suitable for moisture-loving, hardy, herbaceous, and other plants.—EDITOR.]

GARDEN HEDGES.

While some people in regard to garden hedges seem to have no ideas beyond Green or Golden Privet, it still remains an actual fact that the material available for hedges presents a very wide range, offering suitable subjects for every position. There is no reason, consequently, why any proposed hedge should not be made a beautiful garden feature. Even to ensure privacy, ugliness need not and should not be tolerated. If Privet *must* be employed, the golden form is a thousand times better than the green, and can be grown equally as dense. Only, to maintain the bright colouring of the leaves, refrain from making the ground over-rich. If everybody agreed with the writer, the majority of the green Privet hedges would soon be scrapped.

A warning, however, should have gone in front of all this. Hedges *are* grave concerns. Overhaste to plant them is to be deplored. Hedges are the curse of thousands of tiny gardens—front and back. In such there is so little space to utilise for flowers that it is positively sinful to occupy it with a permanent hedge that represents so much waste opportunity, robs the soil of nourishment, and also starves the smaller plants of light and air. If there were fewer hedges in our villa and

cottage gardens there would be more room for and more possibility of beauty, and a considerably reduced demand for plants for shady situations. Plants now languishing under the worst possible conditions would take a new lease of life, and a hundred flowering subjects might perhaps be added where now, maybe, there are less than a dozen. If we have to do without, say, Roses and Chrysanthemums, surely that is too great a price to pay for privacy. In such gardens as those described, to add a hedge to the boundary walls or fences is usually a grievous error. Where it is added, it should generally be restricted to the height of the said wall or fence. Against an open fence of wood or iron, an uncommon subject to plant is the Laurustinus (*Viburnum Tinus*), a handsome evergreen, with, from autumn to spring, trusses of dainty white buds tinged with pink. In good soil this can be grown to form a very compact hedge, either low or tall. It does well by the seaside (south and west), and also in the district around London.

Evergreen Hedges.—These are, of course, to be preferred. For a strictly utilitarian purpose, such as barring cattle, there is perhaps nothing better than a combination of Hawthorn and Beech or Hornbeam, the Hawthorn on the danger side or next to the field or common. Holly is not being forgotten. Indeed, it might stand first were it less expensive and if it succeeded in every position. It may be regarded either as strictly utilitarian or as useful and ornamental. Other subjects that are classified in the latter fashion are Yews, *Cupressus lawsoniana* and *Cupressus nootkatensis*, *Thuya gigantea*, *Thuya occidentalis*, and *Thuya orientalis*, Laurels, Golden Privet, Box, and many varieties of *Euonymus japonicus*, all of which are evergreen. *Thuya occidentalis*, the American Arbor Vitae, is generally esteemed for the deep bronzy tint of its foliage in winter. *Thuya Lobbi* might also be mentioned. Fast-growing, it quickly makes a hedge over 12 ft. high, and will likewise soon become thick if frequently cut. *Cupressus lawsoniana* is another rapid grower that will also make a close hedge. For low, compact hedges, select *Retinospora squarrosa* or *Retinospora plumosa*, and *R. plumosa aurea*. These give little trouble once they get into growth. Of Laurels, the Caucasian form is specially hardy, and the Portugal Laurel will make dense growth; but these are more utilitarian than decorative, and for this latter quality we must go to the variety *Prunus Laurocerasus*, the Cherry Laurel.

Planting, etc.—From March to April is about the best period for planting hedges of evergreens. To ensure good growth, thoroughly prepare the ground, digging it 2 ft. deep and working in plenty of manure. Nothing less than this will suffice if the hedge is to "carry on" for years. Two specimens to a yard will be sufficiently close. If dry weather follows planting, the ground should be soaked with water twice a week. In May it is desirable to surface the ground about the plants with a layer of manure 2 ins. thick, put down after a good watering, and left throughout the summer. Prune Laurels in February and August, Yew in August, Conifers in September or October, Privet whenever it has grown in the least degree untidy, Holly in July, Beech, Hawthorn, and Hornbeam in mid-August. As far as possible use a pruning knife. Clipping with the shears mutilates many of the leaves left behind, causing much

disfigurement. Holly ought to be allowed a certain amount of freedom.

Decorative Hedges.—To conclude with purely decorative hedges, which may or may not be permanent, according to requirements, there is nothing better for these than such Roses as the Common China, the beautiful Penzance Briers, and, for greater height, Wichuraiana Roses and *Rosa rugosa* in variety. The majority of these are of rampant growth, but easily trained, requiring nothing more than stakes and wire for supports. The best time to plant is in late October or November, pruning, according to class, in the following March. Spring planting is also permissible, but new growth will be much later in starting. Ground preparation must be precisely as usually recommended for Roses. Lavender, our last shrubby subject for a decorative and permanent hedge, will be highly appreciated. Plant in September. For temporary hedges, often required to provide a screen during summer and autumn, there are Sweet Peas, Scarlet Runner Beans, Morning Glory Convolvulus, Canary Creeper, tall Nasturtiums, and Minas. Plants of all these are easily raised from seeds sown in spring, and, being of an *annual* character, die down and are no trouble to clear away in autumn.

W. F. M.

GARDEN LABELS.

Sometimes we go round other people's gardens with a view to studying the rare plants they have taken their lifetime in collecting. It is always a great disappointment, not to say annoyance, to us when we find the plants are there without labels.

We consider that labels are a necessity in every garden where choice plants are grown. And what garden is there that cannot at least boast of half a dozen or so choice plants?

Three simple types of labels are shown below :—

FIG. 1.

FIG. 2.

FIG. 3.

FIGS. 1, 2, 3.—Garden Labels. The first is undoubtedly handy for hanging on to fruit trees. The second and third are very useful in the rock garden (especially the second) or in the general garden.

Labels should not be too large or too small. The one depicted in Fig. 2 will not be less than 4 ins. in total length, and the wooden tally shown at Fig. 3 should, as the case may be, be from 4–8 ins. long. Shrubs and roses require big labels, rock plants small ones.

The writing on labels should be large, clear, and easily readable. The label shown at Fig. 2, being faced with zinc, is written with special ink. Wooden tallies such as Fig. 3 should be lightly rubbed with white paint, and written with a hard indelible pencil while still wet. Wooden labels need renewing nearly every year, or at any rate they need scraping, repainting, and rewriting. The zinc ones last much longer, but need cleaning from time to time.

Care should be taken when working in the rock garden, shrubbery, or on the borders not to displace labels, or if they are by accident removed, to replace them properly without delay.

Indelible Ink must be used on all metal labels exposed to the air, as ordinary ink would not show up enough and would "run" at the first shower of rain. Various prescriptions have been suggested, but no ink is better than that made by dissolving two well-heaped tablespoonfuls of copper sulphate in a pint of writing ink. The mixture should be kept well corked up, and be thoroughly shaken before and during use, as with some makes of writing ink the copper forms a sediment. A moderately thick and fairly soft nib gives the best results, and labels so written should be allowed to dry thoroughly before being put in the open.

Ink Stains may easily be removed as follows:—See that the hands do not get really wet while the stains are upon them, and taking a piece of ordinary common soap, moisten it very slightly, and rub it until quite dry on the hands. Repeat the process a second and third time, and when nearly dry, well rub the hands together so that the soap gets into the skin. After a few minutes put the hands under the tap and rinse them slightly with warm water, rubbing them together meanwhile. If all the ink does not come off immediately, dry the hands and repeat the soaping in the same way as before. Hands so treated will be fit to use for greeting one's friends in a very few minutes, whereas if they are washed in the ordinary way the stains may stick on for many days.

GARDEN LITERATURE.—See *LITERATURE OF THE GARDEN.*

GARDEN LORE.

To the inquiring mind there is no branch of garden literature more fascinating and in a measure more instructive than Plant and Flower Lore, with its quaint medley of fact, fancy, and fiction.

It is a subject far too complex and of too great a volume for us to deal with it *in extenso* in these pages. But the curious in such matters will learn much concerning the myths, superstitions, folk lore, reputed curative properties, and other attributes of, and relating to, the various objects in the vegetable kingdom, by consulting some of the authorities who have written on these matters. They are many and diverse. We do not pretend to give a complete list of such works, but merely a selected one which will be helpful to the reader who may develop an interest in this department of horticultural literature.

The old herbals are brimful of reputed cures for every ill that flesh is heir to; some of them, it must be confessed, requiring great faith in these later days, and are of undoubtedly overrated efficacy. In other directions Garden Lore furnishes abundant evidence of the simplicity and gullibility of human nature. Quaint customs are sometimes associated with plants and flowers, which also form emblems and symbols in certain circumstances. The Lily was long associated with the Royal Family of France; the Rose, in the days of the Wars of the Roses, bore a significance long since lost; the modest Violet was the chosen emblem of Napoleonic sympathisers.

So the reader in the following works, outside practical gardening, will discover much of this peculiar knowledge that will entertain and instruct him:—

Deas, Lizzie. *Flower Favourites: Their Legends, Symbolism, and Significance.* 2nd ed. 1914.

Dyer, Thistleton. *The Folk Lore of Plants.* 1883.

Folkard, Richard. *Plant Lore, Legends, and Lyrics.* 2nd ed. 1892.

GARDEN MEASURES.—See *WEIGHTS AND MEASURES.*

GARDEN MINT.—See *MENTHA*, and under PEPPERMINT in *POTHERBS.*

GARDEN NETTING.

Netting of some kind is absolutely essential in gardens where much in the way of small wall fruit, bush fruit, or choice vegetables are grown. It is of various kinds, and some of the most important are mentioned, with their uses, below :—

Fish Netting.—This is usually cheap in most fishing towns, and is effective for general garden purposes. It can be used for protecting seed beds from birds, for keeping birds off wall fruit, and for many other purposes. The gardener should not buy it in bagfuls as he is so often asked to, but by the piece, and should see that none of the cords are broken or greatly worn, otherwise the netting will not last long.

Ordinary Garden Netting.—This is made of string or cord in various meshes and qualities. It is exceedingly useful for temporary work over fruiting bush trees or wall trees to keep the birds off them. As a rule it is not very strong or durable, and should be kept as dry as possible. It should always be spread out for a day or two in full sun to dry before being put away.

Peach Netting.—This is a name often applied to the little bags of muslin or other soft white material which are hung up on Peach trees and Nectarines in July for the fruit to drop into. Without its use the fruit would be damaged to a large extent by falling on hard stagings or floors. WASP NETTING, to protect ripening fruit from wasps, is often made of similar material.

Tanned Netting. — This and TARRED NETTING are the two most useful materials of all. They can be used for every purpose to which netting is applied. A few of the most important uses are as a protection for wall, small, and bush fruits; for keeping birds from seeds; for keeping birds out of frames; and even for training runner beans and climbers as a kind of trellis. STRAWBERRY NETTING, the use of which is so well known, is of this class.

Wire Netting.—This, which is made in various classes and of widely varying meshes, has many important uses in the garden. It is most useful for training climbing plants such as Nasturtiums up to form a quick growing, attractive screen. It is useful for training many summer flowering plants outside, or for the more fragile plants in the greenhouse and conservatory. If cut into strips about 18 ins. wide, and a little wire twisted over the cut ends, the strips can easily be bent into half-moons to form what are known as SEED PROTECTORS, which are more fully described in our article on *GARDEN APPLIANCES.* If narrow-meshed wire netting is sunk all round the garden a foot or so below the surface and the same distance above the ground-level, the garden will be protected to a large extent from rodents and other vermin. What is known as GALVANISED WIRE NETTING is quite the best. This lasts for a very long period, instead of rusting away directly as ordinary iron wire netting would do. It should, however, always be well painted before use as a training medium, since otherwise the surface zinc upon it is certain to injure the plants, and may considerably retard their growth.—E. T. E.

GARDEN PAINT.—See *PAINT IN THE GARDEN.*

GARDEN PATHS.

The pleasure of a garden depends in no small measure on its paths. If they are badly made, loose and soft and wet, it is impossible to get about

without discomfort after rain or during a thaw. But proper construction is not the whole of the matter: they should also be in the right positions. In some gardens, especially small ones, there are far too many of them; they occupy so much ground that the area available for cultivation is seriously diminished. Every path should have a definite object. It should lead from the road to the house, from the house into the garden, or from some particular part of the garden to another. There should never be a doubt as to its *raison d'être*. If one will serve two objects, it is a mistake to go to the trouble and expense of making another, and by so doing reduce the space for flowers and vegetables. [A small point, but very important.—EDITOR.]

It would seem to follow that paths should be straight in order to serve their objects in the shortest time; and in the utilitarian part of the garden, where fruit and vegetables are grown, they nearly always are straight. But in the more ornamental parts of the grounds, among the flower borders and close round the house, other considerations prevail. The paths in Nature are never straight. They wind up the hills and down the valleys and meander through the woods, perpetually diverted from the direct line by some obstacle, such as a tree or a bank. The result is charming. There is no monotonous regularity, and the view, instead of being exposed all at once, is unfolded before the eye in a series of pictures. Here, as always, the gardener should endeavour to imitate Nature. He must plan out his paths in curves pleasing to the eye, and, in order not to irritate those who have to use them by sending them needlessly out of the straight line, he must have an obvious reason for every divergence. If a sufficient reason is not already in existence, he must supply it by planting a tree or a group of shrubs. A flower-bed is not a sufficient reason, for it might just as well be anywhere else. Even a lawn between the entrance-gate and the house is hardly a sufficient reason for sending the path round instead of across it, especially as it may tempt many persons to make a short-cut across the grass and so to wear an unsightly track. Hence in such cases the usual tree or group of shrubs at the entrance from the road.

After the paths have been planned, their positions being marked with sticks along which the garden line can be laid, the next thing is their construction. Those between the road and the house which may have to bear heavy traffic should be stronger and broader than any intended merely for foot-passengers and an occasional wheelbarrow. The breadth of the entrance-drive should not be less than 8 ft., and it would be better 10 ft., which is the ordinary width of double gates. It should increase around the front door of the house sufficiently to let two vehicles stand side by side, and, if there is only one set of gates, sufficiently to allow of turning. In the garden itself the breadth need not exceed 4 ft., though grass paths, being considered ornamental as well as useful, are often a good deal more.

Construction. — One method of construction is to excavate to the depth of about 18 ins., making the bottom slope downwards from both sides to the middle. The soil taken out can be used for forming a bank or for altering the level of the ground elsewhere. Along the middle, 3- or 4-inch drain-pipes are arranged; over them is placed a layer 1 ft. deep of broken bricks or large stones which are rammed down

firmly, then a 3-inch layer of coarse gravel rising 2 ins. from the sides to the middle to form a "crown," and finally a 3-inch layer of fine gravel, raked smooth and rolled down hard. The result depends a good deal on the gravel. Some kinds — those obtained from the seashore, for instance—always remain loose. Others are kept firm with very little difficulty, the reason being that they contain an admixture of clay which binds the stones together. When a loose gravel must be used, some dry clay should be procured if possible and sifted into it.

It was contended by MacAdam, however, that an elaborate foundation was unnecessary. If, he said, the surface was made impervious to rain, the natural earth underneath must always remain firm and dry; and all macadamised roads are constructed on this principle. Comparatively little excavating is done; there is no deepening in the middle and no drain there; the lower layers of bricks and stones are much reduced in thickness, but the surface is made as hard and smooth as it can possibly be made, and the "crown" is sufficiently pronounced to run all water away to the sides. In light land this water will soon sink into the ground, but if it collects at particular spots a few "soak-aways" should be made. This is done by digging square holes, lining them with loose bricks, and covering them with iron gratings laid about 1 in. below the level of the path. In heavy land it may be necessary to lay down drains at the sides, and at intervals to make "soak-aways" with pipes leading down to the drains. In such cases the upper end of each pipe should be slightly above the bottom of the "soak-away," so as to trap any mud washed down and to allow only the water to escape. This mud should be cleared out occasionally before it reaches the top of the pipe. In suburban districts the drains can usually be connected with the main drainage from the house, but in the country they must be run into a ditch or into a pond, which may have to be dug for the purpose if nothing of the sort exists.

Further Materials.—Other materials of which paths are sometimes made besides gravel are coal ash, asphalt, stone, and turf. Coal ash and asphalt are not ornamental, and if used should be confined to the kitchen garden. Even there they have disadvantages, for asphalt is apt to get very soft and sticky in hot weather, and an ash surface breaks up badly after frost. Flat pieces of stone are popular, especially for paths in the rock garden. They can sometimes be obtained very cheaply when streets are being repaired. They should be laid down in an irregular patchwork. In the spaces between, dwarf Thyme and other similar plants may be grown.

In the flower garden no kind of path looks better than one made of turf. As the majority of new houses are built on grass-land, all that has to be done in such cases is to mark out and dig the various plots and to leave the turf where paths are wanted. Probably the grass may seem to be hopelessly rough and weedy, but an astonishing change can be effected by cutting and rolling, the worst weeds being taken out completely with an old knife. If seed has to be sown, the procedure should be exactly the same as in making a lawn. Of course, on grass paths the wheelbarrow should be used as little as possible,—never when they are very soft,—and it should not be dragged up or down the edge, but should

be guided over it by means of a wedge-shaped piece of wood. With this precaution they are not much trouble to keep in order. With frequent cutting and rolling, and an occasional scrub with the stump of a broom if moss appears on them, few weeds have much chance.

Weeds on Paths.—In gravel paths it is different. Owing to their gritty nature seeds germinate and grow rapidly, and unless they are destroyed at once they cause a great deal of work. The old method of dealing with them was to use the hoe; the modern method is to apply a weed-killer, though not close to live edgings, for there it might damage the plants. A weed-killer, if in sufficient quantity, destroys not only the growing weeds but also their seeds; the hoe does not injure the latter, and probably passes over some of the former. A weed-killer leaves the surface undisturbed; the hoe breaks it up, leaving it loose in summer and soft and uneven in winter. In all respects, therefore, a weed-killer is the better. There are many excellent kinds on the market, but if the gardener wishes he can make one very cheaply by diluting carbolic acid (No. 5) with from 80 to 100 times its bulk of water. If the surface is thoroughly wetted a single application should keep a path clean for a whole year, provided that the ground is moist at the time and that heavy rain does not fall for two or three days.—H. C. D.

GARDEN PLANNING: AIMS TO BE KEPT IN VIEW.—The nature and area of sites vary so greatly, that it is only possible to make certain general remarks on what are the most desirable aims to be kept in view. The first duty of the designer is so to treat the ground that, with due regard to utility and convenience, it shall be in accordance with the style and calibre of the house, and, above all, that it shall be beautiful and entirely enjoyable. A garden must be a place of repose and charm, with varied forms of interest, each one of which should be kept separate and thoroughly well worked out. Many a garden is spoilt by a fussy jumble of details, each one of which, if treated carefully and quite apart by itself, would be a success: whereas the attempt to display all together is only confusing and distracting, and a place which ought to be for comfort and happiness becomes a source of mental worry, perplexity, and weariness. To take an example: if there is a beautiful distant view from any part of the ground it is better to approach it through a grove of quiet planting, so that it is framed by green things that are not in themselves showy or insistently attractive. If the view is seen over an elaborate parterre full of bright flowers, the full effect of both is lost. The parterre is in place near the house, overlooked from the house itself, or from a terrace immediately adjoining it; it should have its own background, also, of quiet greenery. Some of the most beautiful examples are where there are large trees and a lesser undergrowth—not so near as to rob or overshade the garden, but taking their own place as a dignified background and shutting off the flowery parterre from any other of the garden delights. The same principle holds good in the choice of shrubs and plants; the best result can only be secured by the exercise of an almost severe

restraint. Each portion should have its own character and show some definite intention; although the complete garden, by the skill of the designer, is so linked together that one part follows another in orderly sequence and takes its appointed place in the co-ordination of the whole. The designer should give the place just those trees, shrubs, and plants that it needs and that will best serve to make it beautiful; not one each of a great number of kinds. The different sections of a large garden will provide for the placing of a considerable number of various sorts, but if these are wanted for their own sakes in a garden of small or moderate extent, they should be in a special place and, frankly, as a *collection*.—G. J.

GARDEN PLANS.

A plan for the garden is every bit as important as a plan for the house, and nobody would dream of building without one. Moreover, additions to a house are liable to be awkward unless the original was planned for extension, and this applies equally to the laying out of land. Indeed a definite plan, drawn up when the house is built, is the more necessary, as complete development is seldom possible after the expenses of building have been met. Following a set plan the garden can be continued year by year, and the cost spread out so that really good material and adequate labour can be allowed. Preliminary operations in land cultivation should never be poorly done; a garden stinted in its first stages wears a callow look for years.

What, then, are the points in a garden plan? Let us first consider the ideal plot and its position. Its boundaries should not be too regular in outline, and the road frontage should lie on the northern side. This enables the best rooms to have a sunny outlook to the garden, and also throws the shadow of the house off the terrace. The land should slope (if at all) towards the south-west, and be naturally drained by a subsoil of chalk or gravel. A few matured trees will be an additional attraction. The architect and garden designer should consult together on the exact position of the house, as a few yards one way or the other may make all the difference in the utilisation of existing trees, or economy in working levels. The skeleton plan required by the garden designer shows the boundaries, levels, position of house, and any special features that need to be preserved. All except the latter can generally be obtained through the architect who has needed one himself, but the position of fine trees, etc., may have to be measured by the garden designer. At the same time he will note good and objectionable view points. Diagram A shows a plan ready for his work.

Two distinct styles of garden design are recognised: (1) The formal or geometrical, which is the earliest method of dealing with land; and (2) the landscape style, which aims at imitating Nature. Boundaries are disguised, and the extent of the plot made to look larger than it is by means of winding walks, partially masked by clumps of trees and shrubs growing on artificial mounds. "Let your garden be grand, beautiful, and natural," was the cry of Batty Langley and his followers, whereas Proportion, Unity, and Utility were the watchwords of the formal school. There is no need to touch on the points of the wild controversy that raged round the merits of the two systems, as now most designers recognise both sides, and work on a compromise; treating

the immediate vicinity of the house in accordance with its lines, and gradually blending with the natural gradients of the ground.

However, in small gardens (which are in the majority) there is not space for both methods to be united, and the designer must adopt one or the other from the beginning. Diagrams B and C show identical plots of land treated first in landscape fashion, secondly in formal. It must be remembered that a plan does not show changes of level, and in for success on the arrangement and quality of the trees and shrubs, and unless evergreens are freely used, the garden will be uninteresting as soon as the play of light and shade ceases with the approach of winter.

In the No. 2 designs there is no attempt to disguise the uncompromising nature of a flat, oblong strip. The only disguise (if it can be so called) is introduced by screens, in one case a hedge, in the other a rose trellis, which divides each plot into two compartments. These geo-

Diagram A.

both No. 1's the ground has been partially modelled, and altered from its natural flatness. In B No. 1 the pond lies in a hollow, and the soil from the excavations gives a gentle rise all round on which the summer-house stands, the path ascending thereto. On the other side the shrubs are raised, and the pond and paths are concealed from the house. In C No. 1, the ground has been raised on the S.E. side before the path splits to surround the oval plot, so that a person coming along the path cannot see what lies beyond. Both these examples largely depend

metrical gardens are less dependent on the seasons for their beauty. Their lines are always pleasant to the eye whether sprinkled with snow or in summer verdure. On the other hand, the flat surface gives less variety under sun and shadow, morning and evening lights, as when the surface undulates. They require the utmost care in upkeep, for the least shagginess of grass verge or hedge makes them look forlorn, whereas in a garden treated in landscape style, a little wildness conforms to the general idea.

When additions have to be made

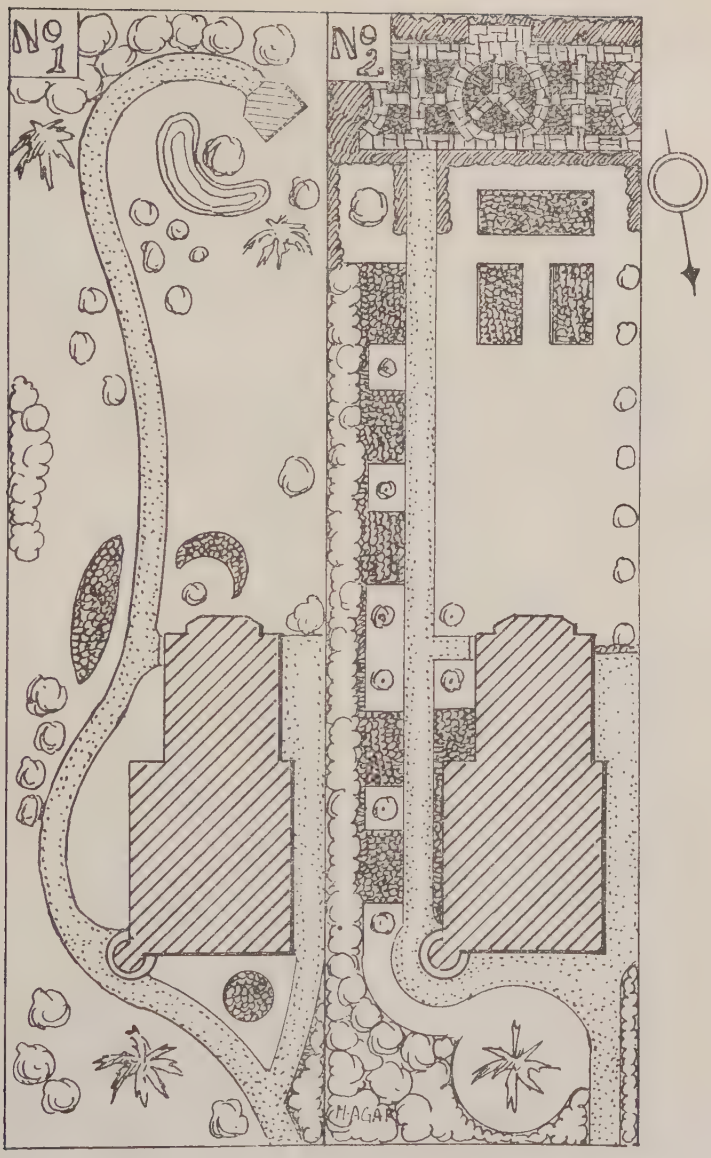

Diagram B.

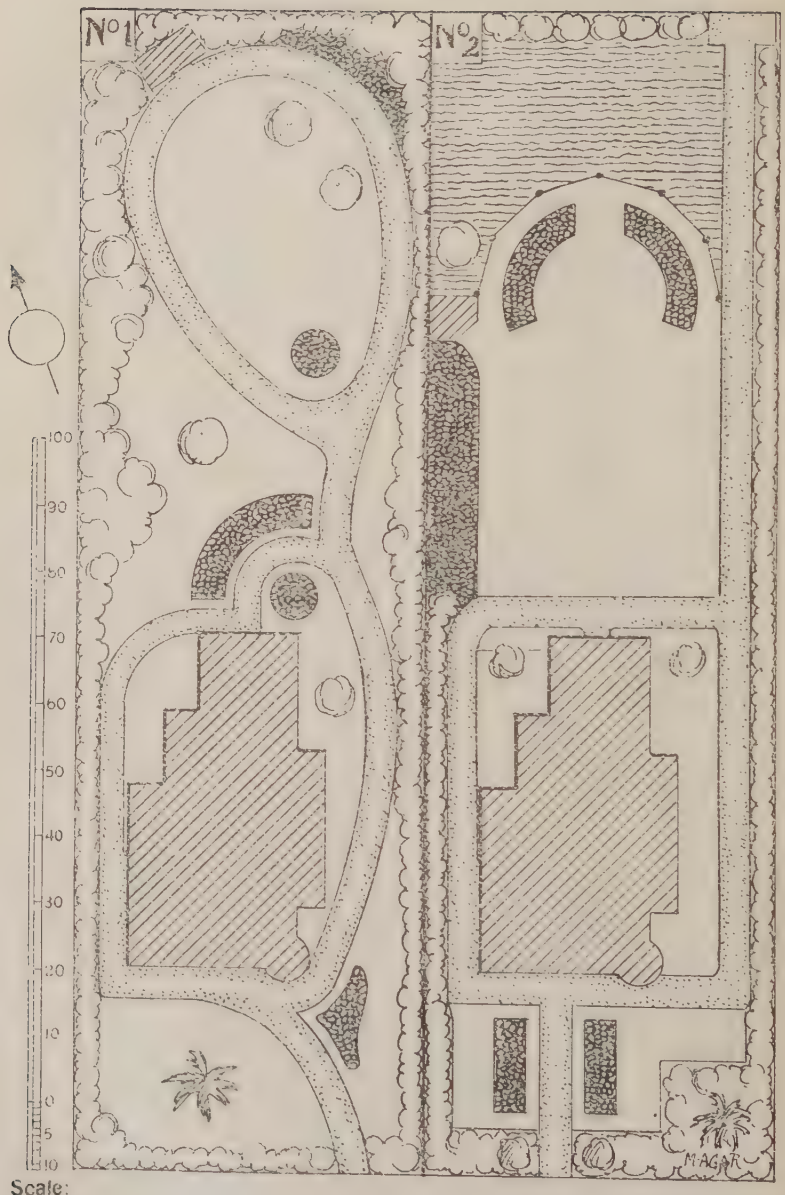

Diagram C.

to a garden for which no provisions exist, the best way is to carry forward the main path into the new land. If this path originally took a turn in order to surround the plot, the turn can be arranged to look as a side path to the new long walk. The boundary hedge or belt of shrubs, no

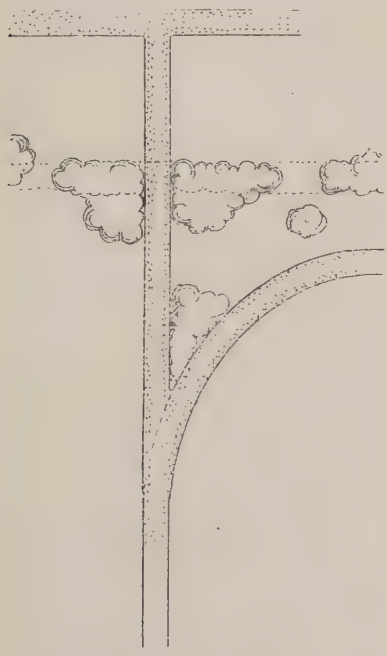

DIAGRAM D.

longer needed for a screen, can have spaces cut through it, and by adding a few extra shrubs, the old hard line can be completely altered. Diagram D shows how simply this can be accomplished. The dotted lines are the outlines of original shrubbery beds and path, and it can be seen how little is needed to change their character.—M. A.

GARDEN POETRY.

If the reader takes up a book, such as the *Garden Anthology*, he will be astonished to find how few poets have written of the garden as a whole, and how many have been content with the description of single flowers, or of the thoughts which sitting or walking in a garden suggest.

Spenser, it is true, in his poem, *The Fate of the Butter Flie*, gives us an accurate account of the garden of his time, but from the catalogue of plants found in it, it is clearly a garden more of sweet-scented herbs and simples than of flowers—and it is worth turning to by the curious in these matters. Milton, too, in his *Paradise Lost*, draws a careful picture of a garden bower, where, mid laurel, myrtle, and acanthus shade, "Each beauteous flower reared high their flourished heads between, and wrought mosaic"; but he perhaps purposely forgets the seasonable coming of the flowers, for he tells us how at the time of rose and jessamine in this garden, the violet, crocus, and hyacinth embroider the ground.

It is not till later times that the poets were tempted to write of the garden as we know it, though we do not forget that Andrew Marvell described flowers in a garden as "at parade," and that Giles Fletcher pictured the garden as: "A lady fair that lay as if she slumbered in delight."

The historic garden in later literature is that "orchard-garden eminently fair" at Townend, Grasmere, which was William Wordsworth's garden and study in one. His descriptive poem was written at the end of May 1802, when he left Grasmere to fetch his bride. We quote some of it below:

"Dear spot! which we have watched
with tender heed,
Bringing thee chosen plants and blossoms
blown
Among the distant mountains, flower
and weed,
Which thou hast taken to thee as thine
own,

. . . . . .

"Oh happy garden! whose seclusion
deep
Hast been so friendly to industrious
hours;
And to soft slumbers, that did gently
steep
Our spirits, carrying with them dreams
of flowers,
And wild notes warbled among leafy
bowers;
Two burning months let summer over-
leap,
And coming back with Her who will
be ours,
Into thy bosom we again will creep."

Keats, whose description of Sweet Peas in blossom is one of the most beautiful in our language, has left us many allusions to flower life, but we must go to Shelley for a real garden poem, and this we find in *The Sensitive Plant*, which is too long to quote, but delightfully dainty in every part of it.

Matthew Arnold in *Thyrsis*, after a fine description of the result of a wind-storm in a garden in early June, gives an admirable account of the second blossom time :

"Soon will the high Midsummer pomps come on,
Soon will the musk carnations break and swell,
Soon shall we have gold-dusted snapdragon,
Sweet-william with his homely cottage smell,
And stocks in fragrant blow ;
Roses that down the alleys shine afar,
And open, jasmine-muffled lattices,
And groups under the dreaming garden-trees,
And the full moon, and the white evening star."

Tennyson-lovers will remember his description of the Somersby garden in Cantos 89 and 95 of *In Memoriam*. They will go to *Maud* and *The Gardener's Daughter* and find many tender touches of garden painting, and if they wish to realise Autumn, its scent, and sight in a garden, they will find no better account of it than in *The Song*. It is, alas, somewhat long to quote here.

William Morris wrote nothing more simple or beautiful than some passages in *The Garden*, such as :

"I know a little garden close
Set thick with lily and red rose,
Where I would wander if I might
From dewy dawn to dewy night,
And have one with me wandering."

There is real charm about this poem, and much the same may be said of T. E. Browne's poem, *My Garden*, which is so terse and epigrammatic that we must quote it in full :

"A garden is a lovesome thing, God wot !
Rose plot,
Fringed pool,
Fern'd grot—
The veriest school
Of peace ; and yet the fool
Contends that God is not—
Not God ! in gardens ! when the eve is cool ?
Nay, but I have a sign ;
'Tis very sure God walks in mine."

Glorious as are our gardens full-lit by summer sun, there is, as T. E. Browne knew well, a charm and mystery which has peculiar power upon our spirits when the sun has set and blue eventide has fallen upon grass and flowers, and this John Keats knew when he wrote his *Summer Night* :

"I cannot see what flowers are at my feet,
Nor what soft incense hangs upon the boughs,
But in embalmèd darkness, guess each sweet
Wherewith the seasonable month endows
The grass, the thicket, and the fruit-tree wild ;
White hawthorn and the pastoral eglantine ;
Fast-fading violets covered up in leaves ;
And mid-May's eldest child,
The coming musk-rose, full of dewy wine,
The murmurous haunt of flies on summer eves."

But with all the gladness of a garden, there is a note of sorrow in the swift passing of its short-lived splendour. Herrick voices this for us in the following lines *To Blossoms* :

"What ! were ye born to be
An hour or half's delight,
And so to bid good-night ?
'Twas pity Nature brought you forth
Merely to show your worth
And lose you quite."

No account of gardens, as described by the poets, would be complete without allusion to Rudyard Kipling's *The Glory of the Garden*, of which I quote the first and last verses only :

"Our England is a garden that is full of stately views,
Of borders, beds and shrubberies, and lawns and avenues,
With statues on the terraces and peacocks strutting by ;
But the Glory of the Garden lies in more than meets the eye.

"Oh, Adam was a gardener, and God Who made him sees
That half a proper gardener's work is done upon his knees,
So when your work is finished, you can wash your hands and pray
For the Glory of the Garden that it may not pass away !
And the Glory of the Garden it shall never pass away !"—H. D. R.

GARDEN RHUBARB (*Rheum Rhaponticum*). — See *RHEUM* and *RHUBARB*.

GARDEN ROBBERS.

Of the enemies the gardener has to fear, none are greater than Garden Robbers. These are not usually grown men and women, but young scamps or juveniles of both sexes, who rob gardens more for the sport of the game than for the produce they get.

We consider it is of little use to praise the existing treatment of such scamps. English Law treats them badly and often makes them worse instead of better. We may say that we consider girls as bad as boys in robbing gardens, especially the "tomboy" girl, who is, alas! so common in modern times.

The old way is to catch your robbers first and then summon them at the local Police Court. They may be sentenced to gaol, or to a reformatory, for the paltry offence of stealing a few apples, pears, cabbages, or peas. In either case they come out worse than they went in; they have been in most cases hardened instead of mortified, and are determined to "get their own back somehow." They have learnt all manner of tricks during their confinement, through contact with persons worse than themselves, and when they get out again they very often do something far worse than the stealing of apples.

The method below would, if adopted, be much simpler, more effective, and better in every way. It is well known that most young persons of modern times hold a respectful dread of corporal punishment, and advantage of this should be taken. The birch for the boys and the cane for the girls would, if properly used, soon stop them robbing gardens. The young scamps know they have only got what they deserved. They are not taught worse mischief as is the case when they are sent to prison or reformatories, and they soon learn to realise that stealing will not do. One of the contributors of the Dictionary, a gentleman we have the highest respect for, told us when we were chatting the other day about garden robbers of his method of dealing with them. When first he went to live at a new house in the country he was continually losing his apples, and when it came to a valuable new tree being stripped of fruit he determined this sort of thing must stop. He knew that the thieves were a group of rough young people in the village. The following night he had a dish of apples brought into the library, and he determined he would sit up. His two gardeners lay concealed in the garden near the orchard, and about ten o'clock some of the young scamps appeared. Two of them—a boy and a girl—got into a tree and started pitching apples down to the others. The gardeners came upon them unawares; the rest of the robbers escaped, but the two in the tree were caught and marched up into the library. Our friend was waiting for them, and when the gardeners had withdrawn from the room, he turned to the boy, "Young man," he said, "you have been stealing my apples. Don't you know it's wrong to steal, eh? Well," he continued, "you must learn your lesson this once. Get over that chair!" Our friend gave the young scamp a dozen biting strokes with his cane. Then he turned to the girl. "Now, young lady," he said, "if you think that because you are a girl I shall let you go without feeling this, you are mistaken. Get over that chair at once!" "Yes," he told us, "I was bold enough to give her six

cuts of my cane, and she never murmured a sound. After I had caned both of them," he continued, "I sat them down by the table, and handed them the apples. At first they would not touch them, but at length I managed to induce them to eat two each. After they had finished I told them that when they wanted some apples they were to come and ask me for some, and then I let them go. I have never lost any apples since. That's the way to treat them," he concluded, smiling—"no prison or legal proceedings, simply a homely but effective way," and we certainly agree with him.—E. T. E.

GARDEN SUMMER-HOUSE, THE. A pleasantly placed and planned summer-house is so great a gain in a garden that it is well worth considering how it may best be made useful, besides serving as an attractive feature in the garden landscape. The planning of the grounds will govern its position, but it is generally understood that it is a place of temporary rest from which there is a good outlook on flowers and pleasure ground or on some beautiful distant view. It may be anything in quality or degree from the Banqueting House of our Tudor and Jacobean ancestors to the simplest structure of slab and thatch; but nothing is more desirable in any garden than a really comfortable summer-house—such a place as may be used as a quiet retreat for reading or writing in the summer months. There may often be seen some little building, say of 10 ft. square, that might well serve such a purpose, but that is quite useless because it is not properly lighted. If the light comes only from the entrance opening, it is never comfortable, but a window at the back or side makes all the difference. It is all the better if the little house can be entirely closed and have a fireplace, for then it becomes available as a tea-house—pleasant for grown people and a delight to children. Whether opened or closed, if the walls cannot be all of brick, there should be a brick base that comes three courses out of the ground; a wooden framework is then built, to be covered outside with elm weather-boarding. The roof may be also of weather-boarding or of thatch or tile. Thatch is warm in winter and cool in summer, but is apt to be much pulled about by sparrows, and is difficult to repair, though it has a good appearance. Tile is best—permanent and well-looking. The inside should also be boarded, the boarding continued on the under-side of the rafters. This is also best of elm, and if properly done makes the whole snug and completely weather and draught proof. "Slab" is the word used in timber yards for the outside of the tree trunk first sawn off; slabs also make a good side walling for a summer-house; their edges are first trimmed straight and they are then nailed on upright to the framework; oak are the best, and if set on the brick base will last for many years, though they are rather less durable than weather-boarding. The floor should be of

flagstones, paving brick or tile, or cement. If there is a fixed seat its proportions should be carefully considered; but the following measurements may be advised: the seat itself 17 ins. from front to back and 15 ins. from floor to its upper side. The back of such seats is usually made to slope too much, so that it does not rightly support the spine; if it slopes back one inch in six it will be enough.

There are many examples throughout the country of well-built summer-houses, both open and enclosed, dating from the time of Elizabeth to the early years of the nineteenth century. In the case of palatial places some of them were purely for decoration; such as the pillared pavilions or domed temples of Palladian architecture, the purpose of which was solely to secure a dignified full-stop to a garden vista. But in both earlier and later, as well as contemporary, examples there were delightful little houses of one room, of stone or brick, as carefully planned and built as the main house, and closely related to it in character and decoration. In some of the larger places they stand as a finish to the end of a raised terrace, giving a commanding view of the parterre below, or they were reared at the four angles of a great wall that enclosed the flower and vegetable garden. These are commonly of two storeys, the ground floor serving as fruit room or root store or some such purpose, and entered from the garden level, while above is a beautifully finished room with access from a raised terrace or "mount" and perhaps directly overlooking the moat.

There are but few good examples of garden houses from the earlier part of the nineteenth century till lately, but, with the revival of interest in gardening and a more intelligent comprehension of all that it embraces, the need of a better class of summer-house or garden-house has been felt, and the architect is now called upon to design them, more especially as so many people now take a wholesome pleasure in having their meals served in the open air.—G. J.

GARDEN SUNDIALS.—See SUNDIALS in *GARDEN FURNITURE*.

GARDEN SWEDES.—See *SWEDES*.

GARDEN SWIFT MOTH.—See *INSECT PESTS*.

GARDEN TENTS. — See TENTS in *GARDEN FURNITURE*.

GARDEN TOOLS.

The tools employed in gardening are many and various; and on their judicious selection, and the treatment subsequently given to them, time, labour, and efficiency depend. They should be strong enough to do satisfactorily the operations for which they are designed, and their size and weight should, so far as is practicable, be adjusted to the physical capabilities of the user. Large and heavy tools that can be easily handled by a strong and experienced labourer may prove altogether unsuited to the amateur who does gardening solely as a spare-time hobby. On the other hand, tools so fragile as to be unable to stand any strain are obviously useless. Fortunately, many tools now on the market are made with the view of minimising the amount of physical exertion and economising time in working.

The care of the tools is a matter that should receive some consideration. In large establishments, where the equipment is more or less complete, a tool-shed is usually provided. There the old motto should be enforced: "A place for everything, and everything in its place." But however few the tools, it is bad policy to leave them lying about exposed to all weathers; not only is their period of usefulness seriously curtailed, but the labour involved in using them is considerably increased. A corner, therefore, should be found for them under cover. All soil implements should be scraped clean, and the iron or steel points wiped with an oily rag; further, if put away for any

length of time, they should be looked over occasionally, to see that rust has not started on them. Tools used for cutting, such as pruning knives and saws, sécateurs and shears, should be wiped free from sap and moisture. A file will be found handy for keeping a sharp edge to spades, hoes, etc.; and a hone will be equally serviceable for tools with cutting blades.

Of the tools required for cultivating the soil, the spade, fork, and hoe are the most important, and should be provided in even very small gardens, being regarded as the minimum equipment. In practice it will be found convenient and helpful to supplement these with others specially adapted to different uses; while in large gardens, where the work is more complex, these other tools are an absolute necessity to save labour and ensure efficiency. The following are among the principal tools employed. With some of them patterns vary considerably with the different makers. See also *GARDEN APPLIANCES*.

Aphis Brush.—For removing aphides (green and black fly) from Roses and other plants. The handle is of brass or steel, and is bent so that the brushes at each end face one another. A gentle pressure causes them to meet on the infested shoot, which is thus effectively cleaned.

Bill-hooks.—Long, flat, variously-curved blades, in a short handle, used for cutting undergrowth, small branches and hedges, pointing stakes, etc.

Brooms.—The best are made of Birch twigs. They should be kept dry, and well moistened before being used.

Daisy Grubbers.—Steel two or three-pronged forks fixed in a wooden handle, and with a projection at the head to give leverage in uprooting daisies, etc., from turf. *Dock Grubbers* are similar, but larger and stronger.

Dibbers or Dibbles.—For making holes in which to insert plants, bulbs, potatoes, etc. They may be all wood, or have the end sheathed with iron or steel. To ensure evenness in depth of planting, a transverse peg is sometimes fixed at the requisite distance from the point. A good dibber can be made from the handle of an old spade or fork. See article on *DIBBERS: THEIR USE AND ABUSE*.

Edging Irons (also called *Verge Cutters*).—A half-moon or crescent-shaped blade affixed to a long handle, for trimming edges of lawns, beds, etc. It should be kept well sharpened, also wiped dry and greased before it is put away. Where there is much work to be done, it is best to use an edge-cutting machine, on the principle of the lawn-mower.

Flower Gatherers.—Scissors so made as to hold the stem of the flower when cut, doing away with the risk of its falling and getting damaged.

Forks.—These are made in many styles, suitable for various purposes. For digging, especially on medium soils—neither very light nor very tenacious—the three-tined or four-tined fork is better than the spade. The tines should be flat or square, and nearly straight from tread to point, with the object of minimising the amount of exertion required. For breaking up subsoil when trenching, lifting Potatoes, fining down surface soil, etc., a lighter fork with four narrow tines is useful; and for lifting and spreading manure, an even lighter one, with four or five curved tines and a longer handle, is the best. For weeding and stirring soil amongst plants, a handfork with three broad tines, in a handle from 6–15 ins. long, is serviceable. A modification of the fork, with the tines at an angle of about 90 degrees to the handle, is sometimes used for weeding, and cultivating the soil among Potatoes, Strawberries, and other plants that send out runners.

Grass Hooks.—Short, scythe-shaped blade, for cutting tussocks of coarse grass, trimming hedges, etc.

Hoes.—These are of many shapes, adapted to various uses, such as aerating the soil, keeping down weeds; forming a loose layer of earth on the surface, to conserve soil moisture and save watering; thinning out plants; making seed drills; and breaking down the surface for seed-sowing. The Dutch or push hoe is of several widths, with the blade at an angle of about 30 degrees to the handle. It is pushed away from the operator, and is especially useful on light soils, and for working among plants in beds and borders where it is inexpedient to tread.[1] The draw-hoe is also made in several widths, and is best with a curved or swan neck. This form is to be preferred for heavy work, and for earthing-up soil, etc. Some hoes

[1] The *Sproughton Hoe* will probably supersede the Dutch tool in the near future.—EDITOR.

have movable blades, allowing for different widths to be used with the same neck and handle. The drag or "cultivator" is another form of hoe with three prongs instead of a blade, and is useful for loosening the soil among growing crops. For thinning out Onions, Parsnips, etc., hoes or spuds with flat, narrow blades, 2–4 ins. wide, are procurable. The Canterbury hoe has two or three prongs, but is often double-headed, making a combination of drag and mattock. With the pronged side the soil can be loosened, weeds pulled up, etc.; the other side can be used for breaking down clods. Heart, or diamond-shaped hoes, are made for taking out drills, though this can also be done by working the draw-hoe sideways. Swan-necked hoes with short handles are useful for greenhouse stagings, window boxes, etc.

In large plantations, where space permits, horse-drawn hoes or cultivators are often used. There are several modifications and combinations of hoe, fork, and spade, with three to five prongs, which are particularly useful where much work is to be done, or the soil is very heavy.

Knives.—These vary in shape according to the purpose for which they are designed. Budding knives have the blade straight, curved, or angular at the point, while the end of the handle is usually thin, round, and flattened, for raising the bark of the stock. Pruning knives have the blade sometimes straight, but more often curved forward, the better for cutting stout shoots. Propagating knives resemble thin-bladed budding knives.

Mattocks.—A form of pick having one end pointed, the other flattened and sharpened. It is useful for breaking up soil, cutting tree roots, and for other similar work. In the grubbing mattock the blades are shorter, and another pattern has both ends flattened, one being at right angles to the other.

Measuring Rods.—Strips of wood, $1\frac{1}{4} \times 1\frac{1}{2}$ ins. square, and 8–10 ft. long, marked off at regular distances, such as 6, 12, and 15 ins., to secure even planting in the rows.

Rakes.—For removing weeds and stones, fining and levelling the soil, and making a seed-bed, steel-toothed rakes give good results. The number of teeth varies from six to fourteen, and in the best types they are riveted to the bar. For lawns and paths, wooden-toothed rakes are best. They are broader, but lighter; and if strongly made are effective for most other purposes. Hay rakes, also of wood, usually have fourteen to seventeen teeth; Daisy rakes, used on lawns, have a number of teeth closely set.

Scissors.—Pruning scissors have one broad, flat blade, and another narrow and curved. Grape scissors, for thinning the berries, must be light, with thin, tapering blades.

Sécateurs.—Safer than pruning knives in inexperienced hands, though not used so much by expert gardeners. Made in several patterns, but mostly with curved or parrot-bill blades. The spring should be powerful, and a good tool should make a clean cut, not crushing the edges of the shoot.

Shears.—For pruning hedges these may have a notch at the base of the blade, for better cutting stout branches, but often the blades are quite straight-edged. This shape also serves for cutting lawns. For trimming grass edges the blades are straight, but at an obtuse angle to the handles, which also are longer; sometimes a small guide-wheel is fitted at the side. When using them, cut with top blade only. For low-growing trees, short-bladed shears with long handles are used.

Shovels.—Thinner and broader than spades, with the sides and head curving over. Being lighter, they are useful for loading barrows, gathering up crumbs of soil, etc.; but cannot take the place of a spade for digging.

Spades.—Invaluable for cultivating light soils, or those which are so heavy that they have to be cut up in digging. The blade should be straight, and there should be little curve from point to handle, so as to save labour in digging. Keep clean while using, and when putting it away, scrape off all soil and wipe with an oily rag. File the edge when it gets blunt.

Tree Pruner.—For pruning standard trees and tall branches. One blade is fixed to a long rod; the other is free, and is operated by a lever, the handle held by the operator. This is sometimes called an Averuncator.

Trowels.—The blade is of iron or steel, and should not be too cupped, or it is apt to clog in stiff soil. A broader form is made for lifting and planting bulbs. Fern trowels have longer and narrower blades.

Turf Beater.—A flat, oblong piece of wood, with a handle fixed at an

acute angle. It should be fairly heavy, and is used for beating down turf, firming soil, etc.

Turf Cutters. — Either heart or crescent-shaped, with a curved handle. Used for lifting turf, which should first be cut into strips with the edging knife.—W. J. C. [Some miscellaneous tools with which the gardener should be provided include the following: axes, chisels (for wood and stone work), crowbar, garden ruler, garden pencils (indelible), glass cutter, hammers of various sizes, hatchets, mallet, mops, mortar trowel (for pointing buildings), pickaxe (to supplement mattock), putty knife, saws of various sizes, scythe, and scythe-stone, soldering iron (for repairing leaking water cans), and whetstones. For water-cans, lawn-mowers, and other similar "tools," see article on *GARDEN APPLIANCES*.—EDITOR.]

GARDEN VASES.—See VASES in *GARDEN FURNITURE*.

GARDEN WALLS.

For the production of perfectly ripened high-class fruits, walls are necessary, and brick is to be preferred, being porous, absorbing and retaining the sun's rays. Walls may vary in height, from 8–14 ft., or even 16 ft.; up to 10 ft. they may be 9 ins. thick, but over 10 ft. must be 14 ins. in thickness. Fourteen feet may be considered high enough for the development of the trees, as well as for conveniently training the branches and gathering the fruit. A coping of stone, or cement blocks 3 ins. thick and projecting 3–3½ ins., with a drip groove close to the edge, adds to the usefulness and appearance of the wall; and brackets should be built into the face of the wall on which to place temporary 9-inch coping-boards fitting close under the stone coping, to protect the blossom from spring frosts. Nails or hooks may be fixed into the boards from which to suspend mats or other protecting material.

Supposing the ground to be enclosed is an acre in extent, it is better where possible to form a "parallelogram" rather than a square, owing to the fact that a South wall is very much more valuable than is one facing East. A North wall too is more valuable than one facing East or West, for North Borders (see article on this subject) are then possible. So where circumstances permit, make the lengths of the North and South walls half as long again as the walls facing East and West, *i.e.* 3 : 2. This "parallelogram" form is much more pleasing to the eye than is a solid square.

For a garden of an acre the North wall may be 14 ft. high, the East and West walls 12 ft., and the South wall 10 ft., that is if the ground is nearly level, but on a gentle slope the breakings may be a foot less.

The South side of the North wall should face the sun about noon; in the warm parts of the country it may incline to the East, facing the sun at eleven o'clock. In colder climates, where Peaches do not ripen to perfection, it may incline to the West, facing the sun at one o'clock, the sun having greater power in the afternoon; thus the fruit will receive the maximum degree of heat.

Walls may easily be wired. This is a great improvement on the old system of shreds and nails, and a saving to the wall. Galvanised wire strained horizontally along the face of the wall is the best material, though some say it should be painted. For Peaches and Nectarines, the wires should be 4 ins. apart, and ¼–½ in. from the face of the wall; this distance does not in any way detract from the benefit the trees may derive from being in close contact with the wall, as it may be an advantage to have a circulation of air between the wall and the branches, thus promoting

the ripening process. For Apricots, Cherries, and Plums the wires may be 6–8 ins. apart, and 1 ft. for Pears. Wire No. 13 or 14 gauge is most suitable, and this can easily be tightened by raidisseurs.

Some object to the use of any form of wire, maintaining that the shoots of the trees coming in contact with it is a cause of canker; but in miles of wire we have never found a diseased shoot. To counteract the likelihood of any ill effects, a coating of paint could be applied.—W. L.

[Although Garden Walls find their chief value as a means of assisting the growth of trained fruit trees, and of giving these the necessary protection, some other uses for walls must not be overlooked.

A wall may be built to hide an ugly patch of the garden or adjacent land, and up this Virginian Creeper and other climbing plants may be grown. (See *Climbing and Trailing Plants*.)

It may be thought that this is an expensive way of serving the purpose, and that a hedge or small plantation of trees would be better. Yes, when the gardener or his employer has the patience to wait for them to grow. But where it is desired speedily to conceal a blot in the landscape, such as ironworks a short distance away, rubbish tips, etc., or even a busy high road, the only way to do is to build a wall and clothe it with creepers.

The idea that walls are blots on the garden pictures is untrue. Some walls are very ugly indeed, but none need be. If they are built of less carefully trimmed stone they will be both cheap and effective; climbers or creepers will love them, and cling to the pores of the stone straight away. Red sandstone and brick walls, or those made of artificial stone, are unsuitable for the ornamental parts of the garden, as also are walls built of crystalline rock, such as granite or the various kinds of spar. These may be very suitable for the kitchen garden, though the red sandstone, if used, should have first been proved to be durable.

There is yet another kind of wall —the *rock wall*, used more for supporting higher portions of the garden than for any other purpose. Here again crystalline rock and artificial stone must be banned; good rough pieces of limestone built so as to slope slightly inwards, without the least bit of mortar, form the best walls, and all manner of entrancing rock plants will revel in the niches between the rocks.

Just a word in conclusion about building walls to follow on what our contributor has already said. First of all, get out a good foundation, for you cannot expect to build anything that will stand unless you start well. One yard deep and 2 ft. wide is none too much for a 14-inch wall; but, of course, a greater depth and width must be allowed for a higher ornamental wall. The foundation should be of rough stone well stuck together with good mortar, in which a bucket of cement has been added to every barrowful. Start from the first with a straight line and keep strictly to this. Put on a good layer of mortar, then the bricks, tapping each well down with the mortar trowel. Pass the edge of the trowel along the face of the bricks or stones to remove mortar which has exuded from between when the stones or bricks were firmed. As the wall grows in height keep testing it with a plumb-line to see you are building it perpendicularly—not an easy thing to do for a beginner. When it comes to the coping, put an extra good layer of mortar on to keep the

blocks very firm. After building, go over the wall and thoroughly "point" all the joints. For ornamental walls mortar is better than cement for this pointing, as creepers cling to it more readily.—EDITOR.]

GARDEN WEIGHTS AND MEASURES. See *WEIGHTS AND MEASURES.*

GARDENERS: TRAINING OF.—See *TRAINING OF GARDENERS.*

GARDENIA (Nat. Ord. Rubiaceæ).

This is a greenhouse flowering shrub, growing 2–5 ft. in height, and offering a considerable range in the colour of the flowers. Pot culture is usually adopted, a good rooting medium being old turfy loam, two parts; decayed leaves and peat, half a part each, with a little old mushroom-bed manure, and some coarse sand to keep the whole open. Propagation is best effected by cuttings.

Culture.—Cuttings are best taken in January and require a brisk heat for rooting, say 75° F., the young plants being potted singly, and grown on in a temperature of about 70° F., using the syringe freely to keep down insect pests. Pinch the young shoots to induce a bushy habit of growth, and finally transfer into 8-inch pots as soon as required.

USES.—These plants are largely used for house or table decoration, and the flowers are popular for button-hole purposes. As the different species bloom at various seasons, a long period of flowering may be secured. If grown annually from cuttings, and flowered in 5- or 6-inch pots, the plants remain dwarf and bloom better than older and taller specimens.

Varieties.—The best are florida fortuneana, florida radicans major, ribida, and Thunbergia.—J. L. G.

GARDENING FOR THE VERIEST AMATEUR. — "My goodness, that'll never grow anything!" How many times have I heard the rawest of raw amateurs say that when they surveyed the weed-covered, old tin-besmothered yellow clayey patch that their enthusiastic landlord has optimistically described to them as a "nice little garden"?

And how many times, a year or so later, have I joined the same amateurs, now no longer raw, in a song of praise for the dainty show of flowers, the healthy plot of vegetables, that have replaced the weeds and tin cans in that same garden?

Times without number.

So that my first words of advice to the veriest amateur are: Don't be discouraged by appearances. Get right down to the work, whether you know how to tackle it or not. Experience will very soon teach you the *right* thing to do. And you just can't make any mistakes that matter, at the outset.

Start by pulling up the weeds, by the roots if possible, and picking up the sticks, the larger stones, old tins and rubbish of all sorts; throw them all into a corner and set light to anything that is burnable. Save the ashes. They are useful as manure.

Then sit down with a pencil and a piece of paper and rough out your ideas of what you want your garden to be like—a curly path round the garden, an oval patch of lawn here, two diamond-shaped beds there, a vegetable plot, nicely get-at-able, in the sunniest place, and so on.

Don't be too ambitious in your ideas if you have only a small plot.

You can develop later when you gain experience. And don't bother about what you are going to grow at this stage.

Armed with your plan and a strong, bright spade, not too heavy, next tackle the digging. It is back-aching work, but it is splendid exercise, and it is just wonderful how quickly you get used to it.

Your soil will probably be very heavy clay, or very chalky, or gravelly. But anyway, try to loosen it as much as you can with spade or fork. Many a flower and vegetable root will be venturing down there later on in search of nourishment.

In digging, first take out a trench along the whole width of the plot. Your next step, if you can beg, borrow, or steal some manure, is to put a layer of it in the trench you have just dug. In the absence of manure, use any decayed vegetable matter you can get. Then right alongside this trench, dig another trench, throwing the soil forward to fill the first trench.

The soil from the third trench fills the second trench, and so you go over the whole plot, the soil you took from the first trench, and which you should have put aside, filling the last trench dug. Don't forget to stir the bottom soil in each trench, and remember that digging is easiest on a fine day following a spell of rain.

The beds for both flowers and vegetables should be dug in this way, and then at least you will have laid the foundations for a good show.

After thoroughly raking and breaking the surface soil everything is now ready for seed sowing.

Except during winter or late autumn there is always something worth sowing either for use or decoration, but if you can manage to have your plot ready by the spring so much the better.

Vegetables to Grow.—The following is a first-class selection of easily grown food-crops, herbs, and saladings, to start with, in which a really good variety of each is suggested, and the chief cultural points are given.

Beans.—Have a row of runners along your fence or wall. They are both decorative and useful. French Beans take up a lot of room and are not so prolific. *Hackwood Park* is a good variety. Sow seed in May 3 ins. deep and 8 ins. apart. One pint will sow 30 yds. Commence picking in July.

Beet.—*Crimson Globe* is the best sort. Sow in April thinly in drills 15 ins. apart and 1½ ins. deep. Thin out to 6 ins. apart. One ounce will sow 50 ft. of drill. Ready from September onwards.

Broccoli, Brussels Sprouts, and Cabbage.—It is best to buy plants of these winter vegetables in June and plant them on good ground which has been growing other vegetables, in rows 2 ft. apart each way.

Carrot.—*Model*, a stump-rooted sort, is splendid. Sow in March, April, and May, very thinly in drills 12 ins. apart and 1 in. deep. Thin out to 4 ins. One ounce will sow a row of 50 yds. Ready from July onwards.

Lettuce.—*All the Year Round* is the best sort. Sow weekly from February to August in drills ½ in. deep and 12 ins. apart. Thin out to 6 ins. apart. A pinch of seed gives dozens of plants. Ready all summer and autumn.

Mint.—Buy a small root in spring and plant in any out-of-the-way corner. It will soon spread.

Onions.—*Ailsa Craig* or *Brown Globe* are unrivalled. Sow in February very thinly in drills 1 in. deep and 12 ins. apart. Thin out to 6 ins. One ounce will sow 50 yds. of row. Ready in September.

PARSLEY. — Sow in March the *Moss Curled* variety in drills ½ in. deep and 15 ins. apart. Thin out to 6 ins. apart. Only a pinch of seed is needed in the average garden.

PARSNIP.—*Student* is quite the best. Sow in February thinly in drills 1 in. deep, and 15 ins. apart. Thin out to 6 ins. apart. One ounce will sow a row of 60 yds. Ready in November.

PEA.—*Gradus, Little Marvel,* or *Senator* are splendid. Sow in March, April, or May, at fortnightly intervals to keep up supply, in drills 3 ins. deep and 4 ft. apart. One pint will sow a row 30 yds. long. Ready from July onwards.

POTATOES.—It doesn't pay to grow potatoes in a small garden; their place is in larger allotments. If you are keen on a few rows, *May Queen* or *Sharpe's Express* are good sorts. Plant in April 4 ins. deep and 10 ins. apart, in rows 20 ins. apart.

RADISH.—*French Breakfast* is quite unrivalled. Scatter a pinch of seed weekly in an odd corner (shady in summer), covering with fine soil.

SPINACH.—*Round Leaved* or *Perpetual* will give good returns. Sow weekly from April to September in drills 2 ins. deep and 12 ins. apart, Ready all the year round.

TOMATO.—Buy half a dozen young plants in April, and give them the sunniest possible position. Ready from July onwards.

TURNIP.—*Snowball* is a splendid sort. Sow weekly from April to July in drills ½ in. deep and 12 ins. apart. Thin out to 6 ins. apart. One ounce will sow a row of 40 yds. Ready continuously from June to March.

VEGETABLE MARROW.—Buy a couple of plants in May and plant out on a heap of good soil on your rubbish heap, to give you fruit continuously from August onwards.

Flowers.—Concerning these the first question is:—What flowers to set. This is somewhat a matter of your own choice—and pocket. A few rose bushes, of course, are indispensable, but, personally, I should be content for the first year or so to depend on hardy annuals (seeds of which are sown and bloom the same year) backed up by a few perennials (which, once planted, continue to come up year after year). Geraniums, Lobelia, Marguerites, and the other flower-bed schemes are all very well in their way, but they don't allow one to work on the cut-and-come-again principle that most amateurs desire, and are expensive to buy. Roses and herbaceous plants are quite easy to grow, thriving in any good, rich, well-dug soil.

ROSES.—A good selection of dwarf roses can be made from the following: *Caroline Testout* (salmon pink); *Frau Karl Druschki* (white); *George Dickson* (deep crimson); *General McArthur* (scarlet); *General Jacqueminot* (crimson); *La Tosca* (salmon); *Mme Ed. Herriot* (prawn red); *Mme Melanie Soupert* (golden-yellow); *Mme Ravary* (orange-yellow); *Mrs John Laing* (rose-pink); and *Ulrich Brunner* (cherry red).

Among rambler roses for covering ugly walls or forming archways, a good selection is: *Alberic Barbier* (white and yellow); *Crimson Rambler* (fine crimson); and *Dorothy Perkins* (pink).

USEFUL ANNUALS.—Now for the other flowers. You want to realise your ambition of a garden beautiful and at the same time flowers to cut for the vases in the house are wanted. The following hardy annuals are just splendid for both purposes:

Alyssum (white and yellow); Calendula (orange); Candytuft (crimson, lilac, carmine, and white); Clarkia (white, rose, crimson, salmon, and violet); Coreopsis (crimson and yellow); Eschscholzia (any variety); Larkspur (any variety); Love-in-a-Mist (blue and white); Lupine (blue, white, rose, and yellow); Mignonette (various); Nasturtium (dwarf, in brown, yellow, and red); Poppy (various); Statice (bright rose); Sweet Pea (various lovely shades); and Sweet Sultan (blue, carmine, and white.)

All of these are the simplest things in the world to grow, provided you sow very thinly, thin them out well, giving them plenty of room to grow, water them well when it is dry, and keep weeds at bay. Full directions are given in other articles, so that it is only necessary to say here that all of them may be sown in March or April in tiny drills, drawn with a stick. The seed is afterwards covered in with fine soil, and birds kept off with black cotton.

Pleasing Perennials.—Finally there are the perennials which should have a place at the back of every flower border. Here is a selection, all good for cutting and of fine effect; each one of them being able almost to grow itself: Campanulas (blue and white); Canterbury Bells (various); Chrysanthemums (single, white); Delphiniums (white, blue, and red); Evening Primroses (yellow); Hollyhocks (yellow, pink, white, purple, and red); Michaelmas Daisies (various blue shades); Pyrethrums (various red shades); and Sunflowers (yellow).

The best way to start off with these flowers is to buy plants in March and April. Planted firmly, in well-dug soil, they will give no trouble for years, unless you wish to have more of them, when, in many cases, the roots may be taken up in the spring and divided.

For a show of flowers in the spring, faith should be pinned to bulbs, the commoner varieties of which are inexpensive and exceedingly lovely. The time for them to be planted is in the autumn as soon as the summer flowers are over. When they have finished flowering in the spring they should be lifted and buried in the soil in any odd corner until the foliage has died down and turned brown, when they are lifted again and stored indoors.

Now, there is your scheme. It isn't so difficult, is it? And think of your pride when you take your friends round the garden when it is in its glory, and can say, "Alone I did it!"—W. Bt.

GARDENING LAW.

There are several points in reference to Gardening Law which it is advisable for the gardener to bear in mind, and I propose to try and profitably direct his attention to one or two important subjects connected therewith.

Allotment Gardener's Agreements.—First I should like to refer to the Agreements made with Allotment Gardeners. In those Agreements it is usual to stipulate that the tenants shall have the right during the tenancy, subject to the approval of the Local Authority's Surveyor, to erect greenhouses and other buildings, etc., on the premises, and shall be entitled on the expiration of the tenancy to remove all such greenhouses, buildings, etc., and also all fruit trees, bushes, plants, roots, and vegetables planted or laid down by the tenant in and upon the premises; and that all greenhouses, erections, trees, plants, and vegetables not removed within one calendar month after the expiration of the tenancy shall be deemed

to have become the absolute property of the Local Authority.[1]

Alteration of Character of Garden.—You must not alter the character of the garden without obtaining permission of your landlord. For instance, you must not plant large trees in front of a house so as to alter the view or diminish the light, or turn a grassy lawn into a flower garden, or a flower garden into a lawn. The complexion or character of the garden is a matter for the owner, and no one else has a right to alter that complexion. But if the alteration is in respect to cutting down, grubbing, or transplanting, pruning trees or hedges, and this tends to improve the property, this is allowable; but the gardener must not destroy one kind of hedge and plant another without permission.

Compensation for Improvements.—It is well to bear in mind that you cannot compel the landlord to give you any compensation for fixtures which you have put up and are unable to take away. If, for instance, the tenant has erected a valuable little structure, such as a conservatory let into the ground, he cannot claim any compensation from the landlord for the improvement he has made. It cannot be too well borne in mind that if you make improvements to the premises of which you are a tenant, you make them for the benefit of the owner of the premises. I mention this because it is not unusual to hear of people trying to get compensation for such things from their landlords, and they have been astonished to learn that their claims were without foundation and could not be supported in law.

By-Laws *re* Structures.—If you want to add to the convenience of your garden by building a shed, conservatory, or anything else of considerable value, it is well to inquire into the local by-laws first of all, and the safe thing to do after this is not to fix your structure into the ground or to any other building. Let it simply rest on the ground and be kept in position by its own weight, taking care to construct it in such a way that it is heavy enough not to be easily knocked down or blown out of position. Then you will be quite independent of your landlord's goodwill, for if the structure, of whatever kind it may be, is not fixed to the premises, no one can possibly contend that it has become the landlord's property.

Fixtures of Tenants.—I should like to point out the position of the ordinary gardener as regards fixtures. He may often wish to put up a more permanent shed, greenhouse, or some other kind of structure. In this case it is advisable to enter into an agreement with the landlord as to its removal at the end of the tenancy. If no agreement is entered into, the tenant should be extra careful how he builds it, for if in removing it he damages the landlord's property, the landlord can refuse to let him take it away.

The law on this point is, that anything affixed in such a way that you have to break or damage any part of the landlord's property becomes a landlord's, and not a tenant's, fixture. If it is simply fixed into the brick or woodwork with a screw or two, it will be a tenant's fixture.

Generally speaking, anything which a tenant can lift up or unscrew remains his property and can be carried away by him. But if he has to dig up the ground, chip out any mortar, or break anything in order to separate it from the land or building, he must leave it alone, for it belongs to the landlord.

Fixtures : Sale of, by Tenants.—A point worth noting is, that when your tenancy is up and you leave your garden, you should take all the tenant's fixtures with you. If you do not, they become the property of the landlord.

Should you leave any fixtures on the chance of the next tenant buying them, you stand a very good chance of losing your property. As a matter of law, you lose it directly you leave the premises. It has all become the landlord's property, and you cannot sell it to the new tenant because it is not yours to sell. If you think the fixtures are likely to be bought by an incoming tenant, either make your bargain with him before your agreement expires, or else ask the landlord's permission to leave them on the premises.

Notice to Quit.—In the case of a

[1] It is well to note that Allotment Gardeners who have private land to cultivate, *i.e.* do not hold their plots from the City Corporations, are not entitled to compensation for ejection, and have no legal redress no matter for what reason their tenancy is terminated.—EDITOR.

yearly tenancy, an ordinary tenant is subject to removal at six months' notice, expiring on the same date at which the tenancy began.

The English Agricultural Holdings Act altered the six months to a year in the case of agricultural tenancies, but the Agreement with Allotment Gardeners previously referred to usually expressly defines the period and expressly excludes the operation of the Agricultural Holdings Act.

Private Gardens : Garden Societies.—Where the premises are let solely for the purpose of private gardens or for the benefit and enjoyment of a Garden Society, the same are usually agreed to be deemed not to be a holding within the meaning of the Agricultural Holdings (England) Act, 1883, the Tenants' Compensation Act, 1890, and the Market Gardeners' Compensation Act, 1895, or any of them, and the operation of such Acts in relation to compensation for improvements, is therefore expressly excluded.

Plants or Trees not Removable.—Another important point is, as to the right to remove trees or plants. It is well in this connection to know that at the end of the tenancy in the absence of agreement all the trees and plants in the garden must be left there. Whenever a tenant puts a tree, plant, or shrub in the ground it becomes the absolute property of the landlord as soon as it takes root.

Cutting of Trees.—It is good law that if my neighbour has something on his land which causes a nuisance to me I am justified in going to his land and abating the nuisance myself. But first I must give him notice to abate it himself. So if the branches of the tree of a neighbour spread out over the fence into your garden, you can saw them off level with the fence, because you are entitled to abate a nuisance, and only need to give notice if you want to go on your neighbour's land to abate the nuisance. So long as you keep on your own ground you can do it yourself without any warning.

Right to Prune Hedges.—The tenant has the right to prune hedges, as this is for the improvement of the property.

Tresspass by Neighbour's Fowls, etc.—This is a matter of common occurrence. If your neighbour's fowls do damage to your garden you can drive the fowls, etc., away, and bring an action for damages for the value of the crops destroyed and for the trespass, and you can also take the law into your own hands to a certain extent by capturing the fowls found committing damage and keeping them until the owner pays for the injury they have done. While you hold them in durance vile you must give them sufficient food and water, but you are entitled to keep anything produced by them. For instance, if you capture a hen and it lays an egg during its captivity, you are entitled to the egg. But you must not shoot or otherwise destroy your neighbour's live stock except in self-defence, as, for instance, a dog that attempts to bite you.

Law as to Nuisances.—As regards nuisances it may be well to point out that the ordinary law applies, and that the gardener must not do anything which will be an annoyance or nuisance to his neighbour without obtaining that neighbour's consent. So that gardeners should bear in mind that they may be obliged to stop a garden fire pouring out dense volumes of smoke and to remove smelly rubbish or manure heaps. Also they cannot use night soil, sewage, pond mud, pigsty refuse, or other very offensive, smelly material if the same is a nuisance to the neighbours, and they could be stopped from so doing by injunction.

Law as to Traps or Poison.—It is a criminal misdemeanour to set traps or lay poison in your garden, and if harm comes of it you are guilty of an inhuman act, and are liable to yield redress to the sufferer or, in the case of an animal, to the owner of the creature you have destroyed or otherwise injured.—J. C. A.

GARDENING LITERATURE. — See *LITERATURE OF THE GARDEN.*

GARLAND FLOWER.—A name sometimes applied to various species of DAPHNE, which see in *DAPHNE* and *SHRUBS.*

GARLIC (*Allium sativum.* Nat. Ord. Liliaceæ).—Considering the many uses to which well-grown bulbs or cloves of Garlic may be put by good chefs and cooks, it is a matter for surprise that one rarely sees this grown in our home gardens, the bulk of that offered for sale by grocers and others being imported from abroad. Yet it is a fact that profit-

able returns are assured from plantings made in this country, upon all save perhaps the most uncongenial soils. As substitutes for onions, these deserve a wider recognition, and for this purpose may well receive attention from those who find the cultivation of the latter somewhat difficult, or in those districts much troubled by the Onion Fly.

Culture.—A supply of "cloves" should be purchased as early in the winter as possible, and these allowed to stand in a frost-proof place, on a cool bottom, until February when, providing conditions are favourable, they may be planted in the open garden, after which little or no trouble need be taken. A good open position is of more importance than a heavily manured soil, in fact any soil well manured for a previous crop may be relied upon to give a satisfactory crop of Garlic.

A foot between the rows, and 9 ins. between the sets, is the distance usually allowed, but where no manure has been added, 3 ins. less each way will be a fair distance. Either press the cloves well into the soil with the hand, or plant with a trowel or dibber, burying each with 2 ins. of soil.

The crop usually reaches maturity in early July. When the tops die down, lift carefully with a small fork, and after a few days' thorough baking in hot sun, remove to a shed or store in bags for later use.

GARLIC MUSTARD.—See *SISYMBRIUM.*

GARRYA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS.*

GAS LIQUOR.—See *AMMONIACAL LIQUOR.*

GAS TAR WATER.—See *AMMONIACAL LIQUOR.*

GASLIME.—See *SOIL FUMIGATING.*

GASTRIDIUM (NIT GRASS. Nat. Ord. Gramineæ).—This is a small genus of hardy ornamental grasses of very easy culture. The best known species is *G. australe* (Syn. *G. lendigerum*), which grows about 12 ins. high.

GATES.—See *GARDEN GATES.*

GATHERING FLOWERS.—See *FLOWER GATHERING.*

GATHERING LEAVES.—See *LEAVES: GATHERING, STORING, AND USING.*

GATHERING RHUBARB.—See *RHUBARB.*

GATHERING AND STORING FRUIT.—This is a matter of very great importance, since, if fruit is carelessly gathered and haphazardly stored, much waste of good food results.

Gathering.—APPLES AND PEARS.—Careless picking results in bruising, and bruised fruits can neither be stored satisfactorily nor do they command the highest prices.

Early varieties can be picked as soon as they are of marketable size, and for this reason it takes three or four successive pickings to clear the trees.

Fruit for keeping must be ripe before it is gathered, or it shrivels when stored. Varieties in season in October and November should be picked first, while late keepers must be left on the trees as long as possible to gain in weight, even though a few drop and can only be sold or used as windfalls.

Ripe fruit is easily distinguished from unripe. The seeds of the former are quite brown, and any specimen can be removed from the tree by raising gently with the hand, whereas unripe fruit have to be sharply pulled away.

To prevent bruising when gathering, use either picking baskets padded with sacking or picking aprons. Place each fruit gently in the receptacle—never throw or drop them

in. Again, empty the fruit carefully into the storing boxes or baskets, and do not turn them out roughly. Of course, the best plan is to pick direct into the storage boxes or baskets.

Stone and Soft Fruits.—These should be gathered before they are dead ripe, otherwise they will not travel satisfactorily.

Storing.—Successful storage depends firstly on the care with which the fruit have been handled during picking, and secondly on the suitability of the store.

For the fruit to keep satisfactorily, the storeroom must be—

(1) Well ventilated.

(2) Of an even, low, moist temperature, that between 40–50° Fahr. being the best.

(3) Frost-proof.

(4) Dark.

A cool cellar or any other brick or stone building can be used, but the best store of all is partly underground, with an earthen floor and a thatched roof.

Wooden buildings with corrugated iron roofs are bad, as the temperature cannot be maintained at an even level. Very dry buildings are bad, as the fruit is then inclined to shrivel.

The fruit keeps best when stored in boxes or baskets of about 1 bushel capacity. These may be stacked in tiers so that the space between each layer of fruit allows free circulation of air.

The next best method is to cover the floor and line the sides of the building with about 6 ins. of clean straw (wheat straw for preference), and then store the apples in a heap, 2–3 ft. deep. The straw allows good air circulation round the heap, and keeps it at an even temperature. It also prevents bruising and checks sweating.

Choice Pears should not, however, be stored in heaps, but in shallow boxes or spread out upon shelves or wooden racks. They must be watched carefully, for when once ripe they soon become overripe.

Grapes are often kept in a special store fitted up to hold numbers of bottles containing water, which are inclined at an angle of about 35 degrees towards the centre of the room. When gathering grapes a portion of the vine to which the bunch is attached is cut off on either side of the bunch. One end of the vine is then inserted into the neck of the bottle so that it reaches the water, and in this way some of the late varieties, such as *Lady Downe's Seedling*, will keep right round the year until the new crop is ready to pick.

The keeping quality of fruit even of the same variety differs greatly according to the district in which it is grown, the nature of the soil, the kind of stock on which the tree is grafted, besides the weather conditions during growth and ripening. For instance, apples and pears grafted upon free stocks keep better than those upon crab or quince; fruit grown on light soils, though ripening earlier, does not as a rule keep so well as that on clay soils, and that from grass orchards often keeps better than that from cultivated land. With regard to this point, it does not follow that grass orchards are necessarily to be preferred to cultivated plantations, and it is a well known fact that young trees should not be planted in grass.—R. W.

[For further information on Fruit Storing attention is drawn to our article on *Fruit Rooms and Fruit Houses*.—Editor.]

GAULTHERIA (Nat. Ord. Ericaceæ).

A genus of dwarf-growing shrubby rock plants, suitable for a

shady position. They are propagated by means of seeds sown in a little heat in March. Only two species are worthy of commendation :—

Gaultheria nummularioides.—This has prostrate stems, and evergreen foliage. Flowers small. Site shady. Soil peat. Flowering Period, June to August. Height, 3 ins.

G. procumbens.[1] — An evergreen tufted plant with bronzy leaves. Flowers small, succeeded by attractive berries. Site, half-shade. Soil peat. Flowering Period, July to August. Height, 6 ins.

See also under WINTERGREEN in *MEDICINAL HERBS*, and *SHRUBS*.

GAURA (Nat. Ord. Onagraceæ).

This is a genus of hardy annuals or perennials of easy culture which are best treated as hardy or half-hardy annuals, either sowing outside in an open border in April, or under glass in heat in early March, and planting out later. *G. Lindheimeri* is the species most usually grown. This bears pretty rosy-coloured flowers from June to September, and grows about 1 yd. in height.

GAYA.—Now included in the genus *LIGUSTICUM*.

GAZANIA (TREASURE FLOWER. Nat. Ord. Compositæ).—This is an extremely showy free flowering plant for the greenhouse, or for hot sunny borders in summer. It is propagated by cuttings of side shoots in March and August, inserted in sandy soil under a hand-light or frame, and should be potted in turfy loam, leaf-mould, and sand. Temperature required, 40–50° F.

Greenhouse Species. — *Gazania Pavonia*.—Yellow. Flowers in July. Height, 1 ft.

G. rigens.—Orange. Flowers in June. Height, 1 ft.

G. splendens. — Orange, black, white. Flowers from June to September. Height, 1 ft.

G. uniflora.—Yellow. Flowers in July. Height, 1 ft.

GEAN (*Prunus Avium*). — See *TREES*.

GENERAL MANURES. — See *MANURES*.

GENISTA.—For the best species see *SHRUBS*.

GENTIAN. — See *GENTIANA* and *MEDICINAL HERBS*.

GENTIAN RUST.—See *DISEASES OF ROCK PLANTS*.

GENTIANA (GENTIAN. Nat. Ord. Gentianaceæ).—A most valuable and beautiful family of rock garden plants. They nearly all thrive in well-drained soil with plenty of moisture in summer, and are propagated by division of the roots in autumn or spring. Most species are also easily raised from seeds sown in gentle heat in March.

What to Grow.—The best are briefly described below :—

Gentiana acaulis (GENTIANELLA). —This has closely tufted stems and dark green leaves. Flowers rich blue, with yellowish mark inside tube. Site sunny. Soil rich gritty loam. Flowering Period, March to May. Height, 3 ins. There are several varieties of this, including a pure white one—*alba*.

G. Andrewsii.—A tall growing sort with tufted stems. Flowers rich blue, in terminal clusters. Site, half-shade. Soil rich loam. Flowering Period, July to September. Height, 1 ft.

G. asclepiadea (WILLOW GENTIAN). —A tall sort with leafy stems. Flowers rich purple, in long spikes. Site shady. Soil rocky sandy loam. Flowering Period, June to July. Height, 2 ft. The variety *alba* has white flowers.

G. dahurica (Syn. *G. Przewalskii*). —A sort with procumbent stems growing from rosette of long leaves.

[1] The CREEPING WINTERGREEN.—EDITOR.

Flowers light blue, tinged with purple. Site, half-shade. Soil sandy loam. A biennial flowering in June and July. Height, 6 ins.

G. Kurroo.—Similar in habit to above. Flowers azure blue, spotted with white towards the base. Site, half-shade. Soil sandy loam. A biennial flowering in August and September. Height, 4 ins.

G. lagodechiana.—This has tufted leafy stems and purple-blue flowers spotted with pale green. Site, half-shade. Soil loam. Flowering Period, June to July. Height, 4 ins.

G. lutea[1] (Yellow Gentian).—This has tall stout stems with large leaves. Flowers yellow, in whorls. Site, open. Soil stiff loam. Flowering Period, July to August. Height, 4 ft.

G. Pneumonanthe (Calathian Violet).—Stems slender. Flowers deep blue. Site sunny. Soil boggy peat. Flowering Period, July to August. Height, 9 ins.

G. septemfida.—This has tufted leafy stems and bright blue flowers in large terminal clusters. Site, half-shade. Soil sandy loam. Flowering Period, June to August. Height, 1 ft.

G. sino-ornata.—A low growing tufted plant with narrow leaves. Flowers bright blue, large, and freely produced. Site, half-shade. Soil rich gritty loam and peat. Flowering Period, September to November. Height, 6 ins.

G. verna.—A small tufted plant. Flowers deep blue, with white fringed eye. Site, half-shade. Soil sandy, gritty loam and peat, but plenty of moisture. Flowering Period, April to May. Height, 3 ins.

G. verna alba.—Flowers pure white.

There are many other species suitable for the rock garden, but owing to restricted space are not included in the above list, which contains, however, the cream of those cultivated.—W. I.

[1] The Bitterwort of some authorities.—Editor.

New Varieties.

Gentiana Farreri.—Sky blue, funnel-shaped flowers with white throat, and produced singly. It has leaves in horizontal tufts, and its habit is prostrate.

G. Purdomi.—Vivid blue flowers with white throat, on procumbent stems, 6–12 ins. long.

See also Gentian in *Medicinal Herbs.*

GENTIANELLA (*Gentiana acaulis*).—See *Gentiana.*

GEOLOGY.—See *Garden Geology.*

GEOLOGY, Drift.—See Drift Geology in *Garden Geology.*

GEONOMA.—For the best species see *Palms.*

GEOPHILUS.—See under Centipedes in *Insect Pests.*

GERANIUM (Cranes-bill. Nat. Ord. Geraniaceæ).—A genus of border and rock plants. All the smaller kinds are suitable for the rock garden. They require well-drained soil in sunny positions, and are propagated by division of roots in autumn or spring, also by seeds sown in spring.

Perennial Border Species.—The best are given below:—

Geranium aconitifolium.—Syn. *G. rivulare,* which see.

G. anemonaefolium (Syn. *G. Lowii*).—This is a pink summer blooming geranium, 18–24 ins. high.

G. armenum.—A strong growing species bearing blood-red flowers from May to August. Height, 2 ft.

G. dahuricum.—A useful rich purple flowered species blooming in July. Height about 18 ins.

G. Endressii.—A rose-coloured species flowering from late June to

the middle of September. Height about 12–15 ins.

G. grandiflorum.—A sort with large blue or violet-blue flowers produced in the summer. Height, 12–18 ins.

G. Lowii. — Syn. *G. anemonaefolium,* which see.

G. macrorhizum.—Red or rose-purple flowers of this are produced freely in June and July. Height, 18 ins.

G. malvaeflorum (Syn. *G. atlanticum*). — This large-flowered sort is not perfectly hardy. It bears purple flowers in the early summer, and its height is 12–18 ins.

G. pratense.—There are many varieties of this blue perennial; for instance, *G. p. flore albo* (white), *G. p. flore pleno* (double), etc. There is also a mauve sort which is useful. The flowering period ranges from June to August, and the height from 18–24 ins.

G. rivulare (Syn. *G. aconitifolium*). — This bears white flowers in June, and averages 12–24 ins. in height.

G. sylvaticum.—The double sort (*G. s. flore pleno*) is the best. The colour is hard to define, but is a kind of purple-blue, with veins of crimson. The plant blooms in May and June, sometimes continuing for a long period. Its height is about 18 ins.

G. tuberosum.—Of this there are pink and purple varieties. The plant blooms from May onwards, and is about 18 ins. high.

Rock Garden Species.—The best are those named below :—

Geranium argenteum.—A choice alpine plant. Leaves silvery-white in tufts. Flowers rose-pink. Site sunny. Soil gritty loam. Flowering ing Period, May to August. Height, 4 ins.

G. cinereum.—Tufted plants with silvery leaves. Flowers reddish-purple. Site sunny. Soil gritty. Flowering Period, May to August. Height, 4 ins.

G. ibericum.—A showy plant with large leaves. Flowers blue. Site open. Soil loam. Flowering Period, June to September. Height, 1 ft.

G. lancastriense.—See *G. sanguineum* var. *lancastriense.*

G. sanguineum. — A handsome prostrate plant. Flowers crimson-purple. Site open. Soil stony. Flowering Period, May to September. Height, 6 ins.

G. sanguineum album.—Flowers pure white.

G. sanguineum var. *lancastriense.* —Flowers pink with darker veins.

G. striatum. — Flowers flesh, prettily veined with purple. Flowers from May onwards. Height, 1 ft.

G. Traversii.—Flowers white or pink. Flowering Period, May to July, slightly tender. Height, 6 ins.

GERMINATION OF SEEDS.

Every perfect seed contains a young plant, and germination may be looked upon as the birth of this plant, the beginning of its separate existence, for the seed is as truly a part of the parent plant as a bud. But although the perfect seed contains a young living plant, we see no growth until it is placed under certain conditions. While the seed is kept in a dry place it remains dormant, asleep, but not dead; it is living, and, although breathing is very feeble, it has not ceased. In all living cells, animal or vegetable, we have that wonderful

material, protoplasm, apart from which there can be no life. Under favourable conditions protoplasm is very active, in some cells moving freely, and in all carrying out important physical and chemical changes. When the temperature falls to anything approaching zero, protoplasm becomes inactive, dormant, and so it does when the cells dry up as they do in a ripening seed. Water is essential for its activity. Protoplasm being living matter needs oxygen for respiration in the plant as in the animal; in its absence there can be no liberation of energy in the cells, and protoplasm then becomes inert or dead. In order, therefore, that the dormant plant within the seed may awake and grow, three or four conditions must be satisfied :—

(1) **Moisture.**—Most seeds, if kept dry, live for several years, although we have good grounds for disbelieving the mummy-wheat story. Very few grains of wheat out of a hundred selected would grow after being kept for twenty years. It may be accepted as a rule that the most vigorous seeds are those of the preceding season. When placed in damp soil, seeds absorb moisture, and vital activity soon commences.

(2) **Heat.**—None of our garden or farm seeds germinate at a temperature much less than 40° F., and for rapid and successful germination a much higher temperature is necessary. Most seeds, when dry, can stand great extremes of heat and cold without apparent injury.

(3) **Air or Oxygen.**—As soon as moisture has entered the cells of the seeds, the protoplasm becomes active and respiration increases in vigour. For this, as in the animal, oxygen is necessary, and if seeds are placed in vessels in which there is a mixture of such gases as nitrogen, hydrogen, and carbon dioxide, but with no free oxygen, there will be no growth.

Light.—Probably the influence of light is not altogether favourable to germination; Nature and experience seem to indicate that the seed should be covered except, perhaps, in the case of one or two of our grasses.

Ferments.—The three conditions of moisture, heat, and oxygen being satisfied, the protoplasm of certain cells begins to form compounds termed *ferments* or *enzymes*. Of these there may be many kinds, but usually we find at least three, and their function is to act upon the substances forming the endosperm or the reserve food stored in the cotyledons, and so change their form and composition that they dissolve in the water of the cells and pass down by way of the cotyledons to the young, growing plant.

The most important of these ferments are :—

Diastase, which converts starch into soluble sugar;

Trypsin, which acts upon nitrogenous substances called proteids, making them soluble and diffusible;

Lipase, which breaks down the fats.

Assisting Germination. — We cannot always depend upon finding ideal conditions in the soil when seed-sowing, but we must do our best to assist Nature. Indoors we can regulate them all very easily, especially where we have artificial heat. Out of doors there may be an excess of moisture in the soil which will mean insufficient air or oxygen, and, possibly, a low temperature. Such soils should be well cultivated in dry weather, and everything done to remove superfluous water before seed-

planting is carried out, or the seeds may rot. Long, strawy, farmyard manure should be applied in the autumn to such soils; its decay will produce heat which will tend to dry the soil and raise its temperature, and it will also tend to lessen the consolidation of these heavy soils. On light, sandy soils we have very different conditions; they are dry, warm, and well aerated, and the only difficulty will be lack of moisture. It is an easy matter for the gardener to water the surface of a small plot, but difficult for the farmer to so treat a field, and for both there is a much better method. Although the surface soil may be too dry, there is usually plenty of water below, and what we have to do is to assist its passage up to the stratum of soil where the seeds are to lie. The way to do this is to pack the soil, consolidate it, so that its tiny particles are brought closer together, and the water rises rapidly, passing from particle to particle by capillarity.

The depth at which we place the seeds in the soil for successful germination must depend chiefly on the size of the seed, which really means on the amount of reserve food which it contains. This is intended to feed the young plant until it is able to manufacture its own food, which will not be till the roots are well established in the soil, and the leaves exposed to light and air above the soil. Then, but not before, the young plant will be able to make those substances that form its true food—starch, sugar, fats, and proteids. For the production of these compounds raw material must be taken from the soil by the roots and from the air by the leaves, and light is also necessary to supply the energy. It is evident that if small seeds were placed at a depth of 3 or 4 ins., although the shoot grows rapidly it will probably be an inch below the surface when the exhaustion of reserve food takes place and the plant dies of starvation. In the majority of cases a depth of five times the greatest length of the seed will be sufficient, but no hard and fast rule can be made, as much depends on the other conditions. Making a hole with a sharp stick and dropping in a seed is unsafe; a blunt stick is preferable, but an open trench is safer still.

Time Required.—The time required for germination varies with the kind of seed; our cereals take

TEMPERATURE AND TIME FOR GERMINATION.

Plant.	Minimum Temperature.	Optimum Temperature.	Maximum Temperature.	Time to Germinate.	Time to appear above soil.
Cereals	41° F.	82° F.	100° F.	3 days.	12 days.
Mustard	32° F.	83° F.	99° F.	1–2 ,,	4 ,,
Turnips	46° F.	89° F.	109° F.	2 ,,	6 ,,
Peas	44° F.	89° F.	102° F.	3 ,,	10 ,,
Beans	41° F.	90° F.	105° F.	4 ,,	16 ,,
Cucumber	51° F.	93° F.	115° F.	7 ,,	42 ,,
Clovers	44° F.	88° F.	111° F.	3 ,,	14 ,,
Maize	49° F.	93° F.	115° F.	3 ,,	22 ,,
Carrot	45° F.	88° F.	103° F.	6 ,,	38 ,,
Veg. Marrow	56° F.	93° F.	115° F.	6 ,,	15 ,,

four or five days; the willow only twelve hours; while hard seeds of clover and other plants may take some months. Germination in such seeds is assisted by filing or rubbing the covering or testa (shaking them up with sand, etc.).

The period necessary for germination will depend upon the conditions named above, the temperature being probably the factor which has the greatest influence in shortening the time. The following results have been recorded:—

DAYS TAKEN FOR GERMINATION.

Seed.	At 40° F.	At 50° F.	At 60° F.	At 66° F.
Pea	5 days.	3 days.	1¾ days.	1½ days.
Horse Bean	7 ,,	6½ ,,	4¾ ,,	4¼ ,,
Poppy	10 ,,	4¾ ,,	2½ ,,	2 ,,
Rape	6 ,,	2 ,,	1 ,,	1 ,,
Beet	22 ,,	9 ,,	3¾ ,,	3½ ,,
Maize	—	11¼ ,,	3¼ ,,	3 ,,

The number of days multiplied by the temperature gives what is termed the "Thermal Constant." Thus the thermal constant of the pea may be taken as about 150.

Further information about sowing will be found in the article on *Seed-Sowing*.—W. B.

[The average germination of the principal seeds will be found in our article on *Seed: Average Germination of*.—Editor.]

See also *Seed Sowing*.

GERMINATION TEST. — See *Seed Testing*.

GEUM (Avens. Nat. Ord. Rosaceæ).—The Geum is a really first-class hardy perennial for cutting. It is easy to grow too, and this fact has already commended it to many amateur gardeners. It thrives in any good, light, rich, well-drained soil, in a very sunny open site, and is easily propagated by sowing seeds in sandy soil out of doors in the spring, or by division of the rootstocks in November or February.

Perennial Border Species.—The best are given below:—

Geum chiloense flore pleno (Syn. *G. coccineum flore pleno*).—This is a dazzling double scarlet Geum, of first order of merit. Its flowering period is July, and its height is about 18 ins.

G. chiloense grandiflorum (Syn. *G. coccineum grandiflorum*).—This also has bright scarlet flowers. Its height and flowering period are the same as the above.

G. chiloense Mrs John Bradshaw is probably the most handsome and widely grown of all Geums. Its flowers are of great size, and of scarlet too gorgeous to describe. It is wonderful for cutting. It has two flowering periods, May to July, and late August. *Mr John Bradshaw* is similar, but bears orange-yellow flowers. Both average 18–24 ins. in height.

G. Heldreichii.—The flowers of this are bright orange-red and very attractive. They are freely produced from May to August. Height, 12 ins. The variety of this, named *splendens*, has a R.H.S. Award of Merit and has larger flowers.

G. japonicum.—A yellow summer-blooming species. Height, 12–24 ins.

G. pyrenaicum.—A good yellow

June blooming Geum. Height, 18 ins.

G. rivale, Guildford or Leonard's Variety.—A pretty form of the WATER AVENS. Flowers pink, in bloom May to July. Moist position required. Height, 9 ins.

G. strictum.—A hairy species blooming in late May, June, and July. Height about 24 ins.

G. urbanum (COMMON AVENS).—A good species for town gardens. Flowers are yellow, and given from May to July. Height, 15–36 ins.

Rock Garden Species.—Three species of this genus are essentially rock plants. They thrive in well-drained gritty loam, and are propagated by division in the autumn.

Geum montanum.—A plant of dwarf compact habit. Flowers bright yellow. Site sunny. Soil deep loam. Flowering Period, May to July. Height, 9 ins. (In the variety *aurantiacum* the flowers are orange.)

G. reptans.—A creeping and tufted species. Leaves pinnate. Flowers clear yellow. Site half-shade. Soil deep, very gritty, with plenty of moisture. Flowering Period, June to July. Height, 4 ins.

G. Rossii.—A distinct species with pinnate leaves. Flowers yellow. Soil common. Flowering Period, June to July. Height, 6 ins.

GHENT AZALEAS.—See *AZALEA: HARDY SPECIES.*

GHERKIN.

This is a kind of small cucumber, used mostly for pickling, but sometimes made into fruit pies. It may be grown in the same way as *CUCUMBERS*, articles on the indoor and outdoor culture of which appear elsewhere in this work.

GIANT ASPHODEL.—See *EREMURUS.*

GIANT FENNEL.—See *FERULA.*

GIANT FIR (*Abies grandis*).—See *TREES.*

GIANT HIMALAYAN LILY (*Lilium giganteum*).—See under LILY n *WATER GARDEN: PLANTS FOR THE.*

GIANT PINK (*Dianthus giganteus*).—See *DIANTHUS.*

GIANT QUAKING GRASS (*Briza maxima*).—See *ORNAMENTAL GRASSES.*

GIANT SPOTTED FOXGLOVE (*Digitalis gloxinæflora*).—See *FOXGLOVE.*

GIANT SUNFLOWER (*Helianthus annuus*).—See *SUNFLOWER.*

GIGANTOCHLOA.—See *BAMBOOS.*

GILIA (Nat. Ord. Polemoniaceæ).

This is a large and interesting genus containing numerous annual species of considerable value in gardens. Most of the plants have narrow, elegant leafage, and flower very freely from a sowing made in light soil in September. A March or April sowing, where soil and climate do not favour autumn sowing, will give good results. The charming little plants often known as *Leptosiphons* belong rightly to this genus, and they are delightful for the rock garden. The flowering period extends throughout the summer.

Annual Species.—A few of the best with the briefest possible description are mentioned below. For many others larger works must be consulted.

Gilia achilleaefolia.—Blue-purple. Height, 18 ins.

G. androsacea.—Pink, with yellow throat. Height, 9 ins. The variety *rosea* has rose-coloured flowers, and there is also a white form.

G. capitata.—Blue. Height, 12 ins.

G. densiflora (Syn. *G. Leptosiphon* and *Leptosiphon densiflorus*).—Rosy-lilac. Height, 12 ins. The variety *alba* is white.

G. dianthoides.—Lilac. Height, 6 ins.

G. laciniata.—Purple. Height, 9 ins.

G. micrantha (Syn. *Leptosiphon*

parviflorus rosaceus). — Rose. Height, 9 ins.

G. tricolor.—There are white, blue, and violet forms of this, each with a yellowish centre; and there is a dwarfed strain which is desirable. The largest averages 9–15 ins. high.

Biennial Species.—Only two are worthy of extensive culture:—

Gilia coronopifolia (Syn. *Ipomopsis elegans*). — This and *G. aggregata* have long, tubular, scarlet flowers, which are produced on unbranched, upright stems, 2–4 ft. high, from July to September. They are also known under the generic name of *Ipomopsis*. *G. aggregata* differs from the former by having cobwebbed leaves, and channelled lobes to the flowers. Both are most easy to bring to perfection by sowing the seeds in gentle heat in January or February, growing the seedlings in small pots and planting them out in May. For the usual biennial culture, sow seeds in June or July, pot them up, wintering them in a cold frame or greenhouse to keep the foliage scrupulously dry, and plant them out in May.

GILLENIA (Nat. Ord. Rosaceæ). This genus is of no great importance, and only two species are grown at Kew. These are, however, rather attractive plants, and should be included in large herbaceous borders where space admits of a fairly representative collection. Both the species described below succeed in ordinary garden soil; they may be propagated in the usual way by division of the roots in the autumn or spring, and may be successfully planted from October to March.

Gillenia stipulacea (American Ipecacuanha).—This bears red and white flowers in July, and averages 1½ ft. high.

G. trifoliata (Syn. *Spiraea trifoliata*). —This, the Indian Physic, is similar in its characteristics to the above.

GINGIDIUM.—Now included in the genus *Aciphylla*.

GINKGO.—For the best species see *Trees*.

GIPSY WORT.—See *Lycopus*.

GIRA (*Alnus nitida*).—See *Trees*.

GITHAGO.—Now included in the genus *Lychnis*.

GLACIER PINK (*Dianthus glacialis*).—See *Dianthus*.

GLADIOLUS (Corn Flag. Nat. Ord. Iridaceæ): **Culture.**—Of all the flowers of the garden, none display so great a range of colour as the Gladiolus, and the possibilities are even now far from being exhausted. The markings on the lower petals, in some flowers softly blending and in others in sharp and vivid contrast, add to their beauty and infinite variety. Their tall and many-flowered spikes rising well above the setting of their leaves render them conspicuous among the more spreading plants of the herbaceous border, and give them an air of stately distinction.

There are about a hundred and fifty species of Gladioli, mostly natives of South Africa, of which only eight or ten have been used in the production of the principal races of autumn flowering Gladioli. Three species—*Cardinalis*, with large open flowers of crimson-scarlet with a white throat and lines; *Oppositiflorus*, with long-flowered spikes of pale lilac-white; and *Psittacinus*, with strongly hooding flowers of vermilion and yellow—are probably the chief parents of the Gandavensis race,—the Florists' or *Exhibition* Gladiolus. The Lemoinei race arose from the union of these *Gandavensis* varieties with *Purpureoauratus*, a species having pale sulphur-coloured flowers with deep

red-brown blotches; the violet-blue section being derived probably from *Papilio*, a mottled reddish-purple flowered species. By crossing the *Gandavensis* and the *Lemoinei* varieties with *Saundersii*, which has large wide-spreading flowers of light scarlet or Lincoln red and a finely spotted throat, the CHILDSII and NANCEIANUS races were produced. Lastly, with the introduction of *Primulinus* in 1902, a pale primrose-yellow species with strongly hooding flowers and a light open spike, a new race with beautiful "art" colours has been developed.

A few other species have been used in lesser degree: *G. Cruentus*, a large-flowered species with rich carmine flowers, is one of the parents of *Princeps*, from which a new race is now slowly developing, and *Sulphureus* has been used by Lemoine as a parent of his *Précoce* varieties. *G. Cooperi, Dracocephalus, Eckloni, Quartinianus*, and two or three others have been experimented with, but nothing of any horticultural importance has yet been obtained.

Besides these tall autumn flowering races there are also the early summer flowering varieties, including *G. Colvillei* and *G. C. albus*, a hybrid of *Cardinalis* and *Tristis*, and some of the smaller flowered species—*G. Alatus, Blandus, Cuspidatus, Leichtlini, Tristis*, and *Watsonius*—which are of lesser importance, but are useful for pot work in a cold greenhouse or in frames. *G. Colvillei* is also hardy in sheltered well-drained situations in the warmer counties of England, increasing fast and forming dense clumps. All these are South African species. There are a few quite hardy European species, but only one, *byzantinus*, with bright purple narrow-petalled flowers, is worth growing in the herbaceous border. *G. atro-violaceus* and *G. Crispiflorus*, established in the rockery among low-growing plants, give a pleasing effect.

The distinctive characters of the principal races of Gladioli fit them for various purposes in the garden. For exhibition the GANDAVENSIS race is supreme. Starting with the original seedling raised by Van Houtte in 1841, Souchet in France laid the foundation of the race which now bears its name. Vilmorin and Brunelet carried on the work, and these varieties have now been brought to a pitch of perfection by James Kelway and his son, who have devoted long years to their improvement, and the strain they have evolved form the ideal of the Florists' Gladiolus. The colours are chiefly white, pink, red, and purple, and quite lately the range of colour has been extended by their *Golden Measure*—a pure yellow Gandavensis. These varieties have tall straight close-set spikes with large flowers, and as many as ten or even twelve open at once. They are effective in the border also under some conditions, but are somewhat stiff and formal, and the very fact of their splendour has the drawback that they do not last so long in flower. The CHILDSII race has much of the habit and character of the Gandavensis, with more varied colours and markings, and is less formal. It flowers earlier, is more easily grown, and the flowers come out more gradually, but lack something of the substance of the Gandavensis. The LEMOINEI, NANCEIANUS, and PRINCEPS races are of a different habit, and are more suitable for general border cultivation. The spikes are less stiff and the flowers are generally more open, and since the distinctive feature of these races is the infinite variety of the markings and their contrasts with the ground colour, these characteristics display the individual

flowers most effectively. These as a rule flower more gradually and make a longer display in the borders. They also make good cut flowers; but best of all for this purpose are the PRIMULINUS HYBRIDS or art race, for these have even more open spikes, light and graceful, and the colours include, besides pure yellows and reds, all the art shades of amber, cream, salmon, coral, and terra-cotta.

Cultivation.—There seems to be an impression that Gladioli are difficult to cultivate—that they die out. This is not so. As with all florists' flowers, there are some varieties with uncertain constitutions, but in general, if given proper treatment, there is no flower easier to grow. They can be grown successfully in any good garden soil, but do best in a stiff loam. If the soil is light and porous it must be well mulched, or other means taken to conserve the moisture, which is so essential to them when in full growth and flowering, and in a dry season, in such a situation they may need artificial watering. The most essential condition in growing Gladioli is a deep and well-worked soil, with a good natural drainage, and failures are generally due to the practice of dibbling the corms into the herbaceous border, which has only been surface-dug, or not at all. Being natives of South Africa, they should be given the sunniest and most open situation possible. The ground must be deeply dug and, if possible, trenched in the autumn, adding a good dressing of basic slag or bonemeal, and lime if deficient (*Princeps* varieties, however, seem to prefer a more acid medium). Well-rotted manure may be used if it is buried beneath the top spit. In the spring, a few weeks before planting time, the ground should be again forked over with a dressing of any good "complete" artificial manure.

Planting.—Gladioli may be planted any time from the middle of March to the middle of May, but about the first week in April is the best time for general planting, depending on the season and the state of the soil. They should not be planted while the soil is wet and sticky, and little if anything is gained by planting any earlier, since there is danger of the dormant corms being damaged by cold and wet. The corms should be planted at least 3 ins. deep,—that is, with 3 ins. of soil over the *tops* of the corms,—and the larger and stronger-growing Gandavensis race should be planted 4–5 ins. deep, in order to give adequate support to their heavier spikes. If planted shallower, they will need to be staked early and securely, otherwise the first strong wind will blow them over, and strain them so that they will neither flower well nor produce healthy corms for the next year. After planting, the ground should be made firm, and even rolled with a heavy roller if the soil is light. When the tips of the spikes are all above ground, hoe lightly to keep down the weeds and produce a thin mulch. No watering should be given before the middle of June, however dry the season; if very dry, they may be mulched. About the second week in June give a top-dressing of superphosphate and hoe it in lightly, to be washed down by the rains in June and July. In a suitable soil Gladioli never need any artificial watering, and keep healthy and flower freely whatever the season, but when the conditions render it absolutely necessary, it should be given thoroughly at intervals of a fortnight.

Taking Up.—After the flowering is over, the corms should be taken up,

the first fortnight in October being the best time. They may, however, be lifted from the middle of September (for the earliest varieties) to the middle of November, choosing open weather so that they will come up clean and dry quickly. It is not necessary, or desirable, to wait for the leaves to turn yellow. The stem and leaves should be cut off at once ½ in. above the corm, the roots trimmed away, and the corms spread out to dry. As soon as dry enough—in a fortnight or three weeks—the old corm should be pulled off; it should come away easily with a clean scar. The corms should then be stored away in a frost-free but cool and dry place;—when the corms are *dry* and dormant an occasional cold down to freezing-point will do them no harm whatever, but a damp and warm atmosphere is most injurious, and will cause them either to decay or to start rooting prematurely.

Propagation.—Gladioli are increased by the small bulbils found attached to the base of the corm at lifting. These should be stripped and collected when trimming off the roots, and sown *thickly* as soon as possible (in November) in small trenches 2 ins. wide at the base and 3 or 4 ins. deep, and covered over with the soil, which the winter rains will settle firmly. The following spring these will throw up one or two slender leaves, which in the autumn should be cut off at the surface of the ground. Then take up the young bulbs with the soil, which last is washed away through a sieve. The young bulbs are then collected together with the unstarted bulbils—for usually only a proportion start the first season. The small bulbs can then be treated as ordinary corms and grown on to flowering size, lifting and replanting each year. The unstarted bulbils, which will now be black and partially retted, may be resown in trenches as before—they will all start the second year. The Lemoinei and Nanceianus races, and some of the Primulinus hybrids, will flower from the second season after planting the bulbils, and most will flower the third season. The Gandavensis, Childsii, and Princeps races are longer in coming to flowering size—from three to five years.

Varieties.—The Gladiolus is still in the making and the development is rapid. The tendency of hybridisers now is to mix the races so that eventually the Florists' Gladiolus will include something of all these species that have been used: the markings of *Purpureo-auratus*; the fine form of *Papilio*, and the colour of its "blue" varieties; the size and rich pure scarlet of *Cruentus*; the pure yellow and all the art shades of *Primulinus*; combined with the tall, many-flowered, and perfectly set spikes of the *Gandavensis*. The number of named varieties is very great; there are literally thousands, and any extended list would soon be out of date. The reader therefore should consult the lists of raisers and specialists for the newest varieties, the lists of certified varieties of the Royal Horticultural Society and the National Gladiolus Society, and the registered list of Gladioli in the *Gladiolus Annual* (N.G.S.).

The following select list includes only a few new varieties which are of outstanding merit, or those which have stood the test of time and are still unsurpassed. For full descriptions see the *Gladiolus Annual*.

Pink.—Dawn (Groff), Loveliness (de Ruyter), Panama (Banning).

Purple.—Orby (Kelway).

Rose.—Ariel (W. C. Bull), Brooklands (Kelway), Halley (K. Velthuys).

Scarlet and Red.—Gallieni (Brunelet), Liebesfeuer (K. Velthuys), Meteor (Pfitzer), Princeps (Van Fleet).

Violet-Blue.—Baron Joseph Hûlot (Lemoine).

White.—Europa (Pfitzer), Incontestable, L'Innocence (Vilmorin), Marie Thérèse (Vilmorin), Rathline (W. C. Bull).

Yellow.—Golden King (G. D. Black), Golden Measure (Kelway), Glory of Noordwyk (Van Zanten).

A. J. B.

NEW VARIETIES.

The following are some of the best:—

Abeliard.—Blush, flaked salmon.

Armagnac.—Scarlet and maroon, blotched white.

Chicago White. — Creamy-white, purple markings.

Eldorado. — Primrose, blotched crimson.

Fire King. — Brilliant scarlet, blotched crimson.

George Gordon.—Yellow, lined red.

Loveliness.—Salmon-buff, blotched pale purple.

Maréchal Foch. — Orange-scarlet, flushed maroon.

Mrs Atkinson.—Salmon, blotched purple, edged crimson ; early.

Mrs McAlpin. — Rose-salmon, striped scarlet.

Mrs R. Wordsworth.—Blush, with yellow blotches.

Mrs Swainson.—Soft yellow.

Phyllis Kelway.—Indian yellow.

Picotee.—Cream and rose, edged rosy-red.

Radiance. — Salmon-pink, pale blotches.

Sunspot. — Salmon-pink, scarlet blotches.

Thérèse.—Blush white.

White Beauty.—White, pale lilac blotches in throat.

White Giant.—White, with purple markings.

Wraith.—Creamy-yellow, lined red.

W. J. C.

GLASS.

Obviously glass is almost indispensable to the gardener who wishes to raise subjects early, and we should feel somewhat lost without the greenhouses, frames, bell-glasses, and cloches we use so much. The best glass is that known as 21 oz. Thick plate-glass or glass even slightly tinged with any colour has a detrimental effect on plant growth, and may paralyse promising subjects in a very short time. Glass can usually be cleaned without difficulty by rubbing it with a mixture of fine ashes, pumice, and strong sulphuric acid. If that fails, hydrofluoric acid will remove any stains in a moment. This acid is very dangerous to use, however. It has to be applied with a rubber pad and quickly washed off, otherwise it may dissolve the glass away. (See article on *ACIDS: THEIR USES IN HORTICULTURE.*)—E.

GLASS SUBSTITUTES.

Whilst for transparency there is nothing to equal glass, it is possible to prepare substitutes that will admit a considerable amount of light. These are often useful for repairing glass breakage in a greenhouse, and they are quite serviceable as frame lights where it is desired to save expense. The materials which are employed in the making of glass substitutes are calico or paper. Naturally the cloth is the more durable, but after proper treatment paper will resist the weather to a remarkable degree.

Calico as Glass.—Where calico is employed only fine material should be purchased. The pieces should be tacked somewhat loosely over the frame. Then the following mixture for application to the calico should be prepared :—

Linseed Oil (pale) . .	1½ pint.
Lead Acetate . . .	½ oz.
White Resin . . .	2 oz.

The acetate should be ground with a little of the oil, then the rest added, and finally the resin thrown in. The ingredients must be incorporated in an iron pot over a slow fire. Apply the mixture hot to the calico and leave the material in a loose state for a day. Then stretch out tightly and tack down where it is to remain.

Paper as Glass.—For the paper lights it is best to use cartridge paper. In the first place the paper should be well moistened all over. Then it should be tacked on to the frames as tightly as possible. To prevent the paper from tearing away from the nails a strip of tape should be run along where the tacks are driven in. When the paper dries it will stretch tightly across the frames and it may then be painted with the following preparation. Secure a pint of boiled linseed oil and mix with this a piece of white lead about the size of one's thumb. This is easily accomplished if the white lead is worked up with some of the oil and the remainder is then added. The paper lights will be found to resist rain to a remarkable degree.

Both these glass substitutes, although not completely transparent, admit a considerable amount of light. It may be necessary to repaint them over occasionally to prevent them suffering from the weather.—S. L. B.

GLASTONBURY THORN (*Crataegus Oxyacantha monogyna praecox*).—See *TREES*.

GLAUBER'S SALTS.—See SODIUM SULPHATE in *SODA AND SODIUM COMPOUNDS*.

GLAUCIDIUM (Nat. Ord. Ranunculaceæ).—This is a new hardy herbaceous plant of some promise from Japan. It is of easy culture, requiring no more than the usual treatment. The one species so far introduced, *G. palmatum*, bears mauve flowers in June, and grows about 2 ft. high.—W. J. C.

GLAUCIUM.—See *HORNED POPPY*.

GLECHOMA.—Now included in the genus NEPETA.

GLEDITSCHIA.—For the best species see *TREES*.

GLOBE AMARANTH (*Gomphrena globosa*).—See *ANNUALS, HALF-HARDY: LIST OF*.

GLOBE ARTICHOKE. — See *ARTICHOKES* and *ORNAMENTAL VEGETABLES*.

GLOBE BEET.—See *BEETROOT*.

GLOBE DAISY.—See *GLOBULARIA*.

GLOBE FLOWER.—See *TROLLIUS* and *WATER GARDEN: PLANTS FOR THE*.

GLOBE THISTLE.—A name applied to the genus *ECHINOPS*, which see.

GLOBULARIA (GLOBE DAISY. Nat. Ord. Selaginaceæ).—Dwarf perennials of tufted habit, which thrive well in rather moist, well-drained positions, and are propagated by division in autumn or spring.

Rock Garden Species.—*Globularia cordifolia*.—A mass of prostrate twiggy growths. Leaves small. Flowers blue. Site open. Flowering Period, June. Height, 3 ins.

G. nana.—Like the above, but smaller in all parts. Site moist moraine. Flowering Period, June. Height, 2 ins.

G. vulgaris (BLUE DAISY).—Mats of dark green shining leaves. Flowers bright blue in heads. Flowering Period, June to July. Height, 9 ins.

GLORY OF THE SNOW.—See *CHIONODOXA*.

GLORY PEA.—See *CLIANTHUS*, and under CLIANTHUS in *CLIMBING AND TRAILING PLANTS*.

GLOXINIA (Nat. Ord. Gesneraceæ).—This is a greenhouse tuberous-rooted perennial growing 9–12 ins. high, bearing brilliantly coloured flowers in many shades.

Propagation is best effected by seed, division of tubers, and by leaf cuttings.

Culture.—Seed may be sown as early as January if a temperature of 65–70° F. is at command. From these early sowings plants can be had in bloom in six or seven months. If stock is wanted for flowering the following year, the seed will germinate quite well in a cold house in May or June. To perpetuate any particular variety the tubers may be divided, or increase may be secured by dibbing leaves into sandy soil, or laying them, underside downwards, in a similar compost, having previously slit the mid-rib at four or five points with a sharp knife. A good compost to use for the mature plants should contain equal parts of fibrous loam, leaf-soil, and peat, with a little dried cow manure, and enough rough charcoal chips or coarse river sand to secure proper drainage. A moist atmosphere and shade from hot sun are beneficial, and frequent fumigation is necessary to keep pests in check. (See article on *Fumigating*.)

Uses.—For greenhouse decoration from the latter part of July till the middle of September nothing can beat Gloxinias. By means of successional sowings, as stated above, the flowering period may be greatly lengthened.

Varieties.—There are many named varieties, but the flowers derived from a really good strain of seed are practically as fine.—J. L. G.

GLYCERIA (Manna Grass. Nat. Ord. Gramineæ).—This is a genus of hardy aquatic grasses of little value but appreciated by bog garden enthusiasts. They grow with the least possible attention and spread quickly. *G. fluitans*, the Flote Grass, and *G. maritima*, the Sea Spear Grass, are the two best known species, but *G. aquatica* (Syn. *G. spectabilis*) and *G. distans* are also grown at Kew.

GLYCYRRHIZA.—See Liquorice in *Medicinal Herbs*.

GNAPHALIUM.—See *Cudweed* and *Everlasting Flowers*.

GNATS.

Gardeners are often sorely tried by gnat bites, which, though not usually considered serious, may turn into cases of blood poisoning. Thus it is advisable to protect oneself from these annoying creatures, and this can easily be done by lightly rubbing the face, neck, hands, and wrists with Oil of French Geranium, a non-proprietary article obtainable at most chemists. Gnat bites may be soothed and quickly cured if a little Oil of Myrbane is rubbed over them. Neither of these oils have an unpleasant odour, nor a detrimental effect on the skin, and are comparatively inexpensive.

GOAT MANURE.—See *Sheep Manure*.

GOAT MOTH.—See *Insect Pests*.

GOAT WILLOW (*Salix Caprea*).—See *Trees*.

GOAT'S BEARD.—See *Astilbe*, *Spiraea*, *Tragopogon*, and *Water Garden: Plants for the*.

GOAT'S-BEARD GRASS.—See *Ægopogon*.

GOAT'S RUE.—See *Galega*.

GODETIA (*Œnothera*. Nat. Ord. Onagraceæ).—The Godetias are probably among the most popular of all annuals. Failure in their culture is frequently due to thick sowing or thick planting. Nine or twelve ins. apart, according to variety, is not too much space to allow, if sturdy bushes and a long-continued display of bloom are the aim of the cultivator. For the size of the plants the flowers are large, and as they are well expanded the effect produced is very fine. Godetias are suitable alike for bedding, for

grouping in borders, for cutting, or even for pot culture for greenhouse decoration. Seeds should be sown in autumn and again in spring, if possible where the plants are to bloom.

What to Grow.—Below we describe the best :—

Godetia amoena.—This is the Californian species from which the popular Godetias have been developed, with their wide range of colouring. A few of the best-named sorts are : *Bridesmaid* (bluish rose) ; *Crimson King* (vivid crimson) ; *Duchess of Albany* (white) ; *Duke of York* (deep red) ; *Lady Satin Rose* (rose pink) ; *Scarlet Queen* ; and *Schaminii* (double, long-lasting, soft rose-pink). Dwarf forms are also to be obtained. The above bloom throughout the summer, and average 1–2 ft.in height.

G. densiflora.—A purple, summer-flowering sort about 3 ft. high.

G. Whitneyi.—Of this Californian species there are cream, scarlet, and white forms obtainable. All bloom freely throughout the summer, and average 1½ ft. in height.

GOLD FERN (*Gymnogramme calomelanos* vars. *Chrysophylla* and *Martensii*).—See *FERNS AND FERN GARDENING.*

GOLD MILKMAID (*Ilex aurea mediopicta*).—See *HOLLY.*

GOLDEN BELL (*Forsythia intermedia*). See *CLIMBING AND TRAILING PLANTS.*

GOLDENCALLA (*Richardia elliotiana*). See *ARUM LILIES.*

GOLDEN or CHINESE LARCH.—Names applied to genus PSEUDOLARIX. See *TREES.*

GOLDEN CROWN (*Coreopsis tripteris*). See *COREOPSIS.*

GOLDEN DOCK (*Rumex maritimus*). See *RUMEX.*

GOLDEN DROP (*Onosma echioides*).—See *ONOSMA.*

GOLDEN ELDER (*Sambucus nigra foliis aureis*).—See *TREES.*

GOLDEN FEATHER (*Pyrethrum aureum*). — See *ANNUALS, HALF-HARDY : LIST OF.*

GOLDEN KNEE.—See *CHRYSOGONUM.*

GOLDEN LARCH (*Pseudolarix Kaempferi*).—See *TREES.*

GOLDEN-LEAVED CHESTNUT (*Castanopsis chrysophylla*).—See *TREES.*

GOLDEN PRIVET (*Ligustrum vulgare aureum*).—See *SHRUBS.*

GOLDEN QUEEN HOLLY (*Ilex Aquifolium aurea regina*).—See *HOLLY.*

GOLDEN ROD.— See *SOLIDAGO* and *WATER GARDEN: PLANTS FOR THE.*

GOLDEN THISTLE.—See *SCOLYMUS.*

GOLDILOCKS (*Aster Linosyris* and *Ranunculus auricomus*).—See footnote and note to articles on *ASTER* and *RANUNCULUS.*

GOMPHRENA.—See *ANNUALS, HALF-HARDY : LIST OF.*

GONIOLIMON.—Now included in the genus STATICE.

GONIOPHLEBIUM and GONIOPTERIS.— Both now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

GOOD KING HENRY.—See *CHENOPODIUM* and *MERCURY.*

GOOSE DUNG. — See *POULTRY MANURE.*

GOOSEBERRY (*Ribes Grossularia*).—See *BUSH FRUITS*, also under RIBES in *SHRUBS.*

GOOSEBERRY DIE BACK.—See *DISEASES OF PLANTS.*

GOOSEBERRY MILDEWS, AMERICAN AND EUROPEAN.—See *DISEASES OF PLANTS.*

GOOSEBERRY SAWFLY.—See CURRANT AND GOOSEBERRY SAWFLY in *INSECT PESTS.*

GOOSEBERRY SCALE.—See under BROWN SCALES in *INSECT PESTS.*

GOOSEBERRY SPOT. — See under CURRANT SPOT in *DISEASES OF PLANTS.*

GOOSEFOOT.—See *CHENOPODIUM.*

GOOSEGRASS.—A troublesome weed. See *ASPERUGO, GALIUM*, and *WEEDS.*

GORSE. — The genus ULEX. See *SHRUBS.*

GOURD (*Cucurbita Pepo*).—See *CUCURBITA.*

GOURDS.—See *ORNAMENTAL GOURDS* and *PUMPKINS AND GOURDS.*

GOUTWEED.—For means of control see BINDWEED in *WEEDS.* See also *ÆGOPODIUM.*

GRADING FRUIT.—See *FRUIT GRADING AND PACKING.*

GRAFTING.—See *PROPAGATION OF PLANTS.*

GRAFTING WAX.

Two kinds of grafting wax are usually employed. The first is that which has to be heated before it can be used; the second is always in a soft condition, or, at any rate, can be rendered pliable by the warmth of the hands.

A very useful grafting wax to be used warm is prepared in the following manner:—

Melt together in an old pan one part of tallow, one part of bees' wax, and four parts of resin. Pour the liquid into a pail of cold water and pull the lump that is formed about until the ingredients are well mixed. Another composition also used in a warm state is cheaper to prepare seeing that bees' wax is not needed. The ingredients are eight parts resin, three parts tallow, one part Burgundy pitch, and three parts of red ochre. The materials should be melted in a pan over a slow fire and thoroughly well stirred. Both the above grafting waxes have to be softened by heat before use.

The so-called cold compositions are largely produced by French firms and can be bought ready for use. Where a small quantity only is needed it is best to purchase a tin of this mastic. A good recipe for a liquid grafting wax that is always ready for use is as follows:—

Melt 1 lb. of resin over a gentle fire. Then add 1 oz. of beef tallow and stir well. Take the pan off the fire and pour in 8 oz. of alcohol or spirits of wine. Stir well and replace on the fire until all is well mixed. The utmost care should be taken to avoid the ignition of the spirits, and the safest place on which to prepare the mixture is a closed range. When the wax assumes the consistency of thick treacle it may be stored in tins with tight-fitting lids. This mastic is always in perfect condition for use.

Where a large number of trees has to be grafted, the old plan of using clay is by no means to be despised. This is both inexpensive and efficient. The mixture is composed of two parts of clay and one part of fresh cow dung. Finely chopped hay or grass added to the clay and cow manure will aid in keeping the composition together. As a rule, where grafting clay is employed, it is better to use a piece of rag or something similar to keep the material in position.—S. L. B.

GRAMA GRASS.—See *BOUTELOUA.*

GRAMMATOPHYLLUM. — See *ORCHIDS.*

GRAND OX-EYE DAISY (*Chrysanthemum uliginosum*).—See *CHRYSANTHEMUM: PERENNIAL BORDER SPECIES.*

GRANITE PINK (*Dianthus graniticus*). See *DIANTHUS.*

GRAPE.—See *VINES.*

GRAPE HYACINTH.—This is a favourite name for several species of HYACINTHUS and MUSCARI, but is chiefly applied to *Muscari botryoides.* See *GRAPE HYACINTHS* below.

GRAPE HYACINTHS (*Hyacinthus* and *Muscari.* Nat. Ord. Liliaceæ).—The Grape Hyacinths are a valuable spring-flowering race of bulbous plants. They are very hardy, with one or two exceptions, and they are good doers. *Muscari Heavenly Blue* is comparatively a recent introduction from Trebizond, but it has already acquired a reputation second to none as a "great" garden plant. The Feather Hyacinth (*Muscari comosum monstrosum*) is a quaint and pretty monstrosity

and succeeds very well if grown in pots or pans for cut flowers. The little Cambridge Blue Grape Hyacinth (*Hyacinthus azureus*) comes into bloom with the Snowdrops. It makes an excellent plant for rockwork. Some varieties, such as the old typical Grape Hyacinth (*Muscari botryoides*) and the newer *Heavenly Blue*, do fairly well in grass, and may be naturalised in rough open spaces.

Culture.—There is little to be said under this head, as the different species and varieties are all so accommodating in their requirements. The Feather Hyacinths need a warm position, and in cold districts should be grown in pots. In fact, pot culture gives them such delicate and uncommon colouring that they might well be grown anywhere under glass. They must not be forced very much. *Heavenly Blue* and some other sorts never seem to go completely to rest. They should be lifted on the early side when the foliage is going yellow. Leaf growth commences very early, and it is impossible to keep the bulbs out of the ground for any length of time without some growth appearing. No notice of this need be taken when the bulbs are planted in October if it is not doubled up.

Species and Varieties.—The best are briefly described below :—

Hyacinthus azureus (Syn. *Muscari azureum*).—This, popularly known as the Cambridge Blue Grape Hyacinth, bears delightful Cambridge blue flowers in February. It grows 3–4 ins. in height.

Muscari botryoides.—This is the old Grape Hyacinth with blue flowers in April, on plants 6–9 ins. high. Its variety *album* is a pretty white form.

M. comosum (Tassel Hyacinth).—This, and its variety *monstrosum*, the Feather or Feathered Hyacinth, bear blue flowers in May and April respectively, on plants 6 ins. high.

M. conicum.—This is very like the well-known variety *Heavenly Blue*, and by some it is said to be synonymous. It flowers in April, and grows 9–10 ins. high.

M. Heavenly Blue.—This is one of the finest introductions of modern times. It resembles the old Grape Hyacinth in its general appearance, but has deeper and richer blue flowers and it is a taller grower. It blooms in April and May, and grows 10–12 ins. high in good soil. It has a powerful clove-like scent on hot sunny days, and makes a capital edging for borders or large beds.

M. paradoxum.—This bears very dark, almost black, flowers in May, and grows 12 ins. high.

M. plumosum.—This is useful for cutting if grown in cool greenhouses. It has no real flowers. The so-called inflorescence consists of fine twisting tendril-like stalks, coloured a pale purple in May, and is produced on plants 12–16 ins. high.

M. racemosum (Starch Hyacinth).—This is a pretty deep blue-flowering subject flowering in April, and growing about 6 ins. high.

M. szovitsianum.—This bears large blue flowers in March or April, on plants 9 ins. high.—J. J. & E. T. E.

GRATIOLA (Nat. Ord. Scrophulariaceæ).—This genus, popularly known as HEDGE HYSSOP, is mentioned here for the purpose of drawing attention to the fact that it is quite distinct from the genus *HYSSOPUS* (which see), containing the popular potherb HYSSOP, which herb is referred to in our article on *POTHERBS. G. officinalis* is found wild all over Europe, and is a plant of very little value.

GRAVEL FOR PATH: Amount Required.—See under VOLUMES in *ARITHMETIC AND GARDENING.*

GRAVELLY SOILS, IMPROVING.—See *SOIL IMPROVEMENT.*

GRAVES, BEAUTIFYING.

We are often asked by amateurs who have lost friends as to the best way of beautifying graves in cemeteries and churchyards. Much has been done in the past on wrong lines. Climbing weeds of no value and little beauty, and coarse growing shrubs, have been planted on graves and have not only overgrown their proper limits, but have also spread on to and injured other graves.

Probably the most beautiful yet simple scheme for the winter planting of a grave is to fill it with spring flowering bulbs. Snowdrops at the outer edge, then such as Chionodoxas and Scillas; after these a few Hyacinths; then some Tulips of the May-flowering type; and in the centre either Trumpet Daffodils or paper-white Narcissi.

All these bulbs should be planted in October or November.

For summer planting we hold unorthodox views. The tendency nowadays is to plant in graves all manner of hardy herbaceous plants of rampant growth, which, though exceptionally lovely in borders, lose all their grace when packed close together in small areas. Personally, we would advise those who want to keep graves tidy and with a "cared-for" look on them to avoid such subjects, and revert to the old summer bedding pure and simple. A grave planted, for instance, with *Ageratum Heavenly Blue* dotted with plants of *Lobelia cardinalis* looks far better than one which is a mass of lupines, phloxes, sunflowers, and the like. A very gay display which will last all the summer is made if the grave is planted with *Geranium Paul Campbell*, dotted with *Fuchsia triphylla*, and edged dually with *Lobelia Blue Gem* and *Pyrethrum aureum*. A scheme which is curiously beautiful is easily carried out if the body of the grave is planted with *Geranium Mrs Pollock*, with two or three central dot plants of Golden Privet. An outer band of a good scarlet strain of *Phlox Drummondii* is then planted, after which the grave is edged with *Amarantus caudatus*.

These should be planted out at the end of May, the bulbs being lifted and dried off at the same time.

GRAY BIRCH (*Betula populifolia*).—See *TREES.*

GRAY POPLAR (*Populus canescens*).—See *TREES.*

GREASE BANDING.

Where fruit trees are not sprayed to check caterpillars, etc., it is almost essential to apply grease bands to keep the moths from crawling up the trees to lay eggs from which caterpillars are hatched.

Grease banding can be obtained from any good horticultural sundriesman ready for use, but if a supply is not available ordinary greaseproof paper, easily obtained at stationers, will do in the first instance. The trees to be banded are examined, and if the bark is rough and uneven the applications of the paper will be somewhat difficult if the moths are not to get underneath it. To obviate this get a quantity of soft putty and rub some of this into the bark of the trees about 5 ft. from the ground until a smooth surface has been produced. Then wind the paper round several times so that the band is 1 ft. wide.

Some people think that a 6-in. band is enough, but it is better to be on the safe side. Tie the band on with raffia, or stick down the ends with some non-soluble glue or prepared horticultural cement; and then smear each band thickly with cart grease or prepared grease, supplied by the trade.

It is very important, of course, to grease band the stake which supports the tree, otherwise the moths will crawl up it, and get on to the trees across the uppermost tie. This point is often overlooked by amateurs.

The best time to apply grease bands is early in September. They should remain on right through the winter, or, better still, until the end of April. They can then be removed, scraped, and the grease melted down again for use the following autumn.

Grease bands should be examined frequently during the winter, as some of the prepared greases are apt to set hard, and then, of course, the moths can crawl over the bands. If this takes place the grease should immediately be scraped off, re-melted, and applied without delay. In some cases the addition of a small quantity of mineral oil will obviate this hardening.—E.

GREEN MANURING.

This consists of the ploughing or digging in of some rapidly growing crop specially sown for this purpose. The practice is an old one, and is resorted to in one form or another all over the world. It is particularly valuable where the soil is deficient in humus and where dung or other organic manures are difficult to obtain. The best known instance of green manuring in this country is the ploughing in of the clover-ley preparatory to the sowing of wheat or winter oats, but as this crop is also grown for grazing and hay, it cannot be classed as a green manure crop pure and simple. There is little doubt that more use might be made of this means of enriching the soil, and it is well worth while for every cultivator to consider whether it cannot be profitably employed on his own land.

The object of green manuring is threefold: first, to add humus to the soil; secondly, to conserve the

available food materials that might otherwise be washed out of the soil by rain; and thirdly, to enrich the soil by added nitrogen from the air.

It is obvious that a time when the land is free must be chosen for the growth of the green manure crop, *i.e.* it must take place between two regular crops, hence the term "catch crop" frequently applied to it. Thus the most suitable seasons are the autumn and winter. The green crop is sown as soon as the summer crop is off, or where possible between the rows of this crop before it is harvested, and is allowed to occupy the land until it is necessary to prepare it for the next crop, generally the following spring. Where land can be spared, the summer can, of course, with advantage be used for the growing of the crop which, when ploughed or dug in, makes an excellent manure for, say, autumn-planted cabbage or Seville (giant long pod) beans.

Another advantage of using the late summer and autumn for the sowing of the crop, beyond the obvious one of obtaining rapid growth which is, of course, essential, is that at this season of the year the soil is well stocked with food materials that have been made available during the summer by the action of the soil bacteria. A considerable portion of this food in the form of nitrates is liable to be lost in the autumn and winter rains when the land is bare; if, on the other hand, a crop is growing, it is taken up by the plants and thus conserved. It is obvious, therefore, for the reasons above stated, that the best and most convenient time to sow for green manuring is as soon as possible after the main summer crop, whatever it may be, can be cleared off the land, or before, if it can be done. The manure crop may be allowed to occupy the land through the winter where possible or until the land is required for the succeeding main crop.

The next point to consider is the most suitable crops to use for the purpose. Owing to the property possessed by the members of the natural order Leguminosæ of obtaining nitrogen from the air by the aid of the nodule bacteria that produce and inhabit the small nodules on the roots that are so characteristic of this order, it is obvious that, where possible, these plants should be employed. Vetches, clovers, and lupines are all suitable, and may be used in the garden. It must be borne in mind, however, that a most important consideration is the obtaining of a sufficient bulk of growth; that the growth be soft and sappy and not of a hard, woody nature; and, further, that it be such as is easy to plough or dig in. Vetches, while they cover the ground well and prevent the growth of weeds,—by no means an unimportant consideration,—are rather difficult to dig or plough in, and are apt to leave the ground very hollow in places, whereas clover and lupines, though not particularly quick or luxuriant in growth when planted late in the year, are otherwise preferable.

In view of these facts and especially when the ground can only be spared for a few months, quick-growing non-leguminous crops will often give the best return, and perhaps the most popular of all is mustard. This crop will produce a large quantity of the right type of growth in a very short time, viz. six or eight weeks, and is eminently suitable for sowing in the autumn. White turnips are extensively used, especially in Bedfordshire, and are also very suitable for the purpose. [Use about 2 lb. of either per statute acre.—EDITOR.]

Although it would seem that such non-leguminous crops hardly meet all the requirements we have mentioned, in that they do not enrich the soil with nitrogen obtained from the air, they do not, as a matter of fact, altogether fall short in this particular, because the carbohydrates (starch, etc.) that they contain are used by another bacterium that has the power of fixing nitrogen from the air. Consequently their presence in the soil increases the activity of this particular organism, and thus the soil is enriched by a different agency.

One of the great values of organic matter in the soil is its power of conserving water, which it holds like a sponge, and this is of particular importance to gardeners and fruit growers. While the organic matter obtained by green manuring will act in this way and be often very valuable in the spring and summer following its use, it must not be forgotten that during its growth the crop takes up a great deal of water which is passed out through the leaves and consequently lost to the soil. On damp soils and in parts of the country where the rainfall is high, this is all to the good, but on very light, dry soils in districts with a rainfall below 30 ins., it may be found that the practice renders the soil too dry in the following spring, and gardeners in such districts will be well advised when trying this means of enriching their soil to watch the last point carefully.

Except for the above possibility in certain districts there is nothing but gain to be obtained from the practice, and gardeners are therefore strongly recommended to try this simple and economical method of manuring their land whenever opportunity occurs—that is, whenever they find themselves in the late summer or early autumn with a patch of land that can be spared until the winter or early spring.—H. E. P. H.

GREENHOUSE BUILDING AND HEATING.—Generally speaking, it is the greatest mistake for amateurs to attempt to build and heat their own greenhouses unless they are well acquainted with the principles of constructive work in brick, iron, stone, or wood, and thus to give details here would be beyond our present scope. There are so many ready-made greenhouses which are available comparatively cheaply, and so many ready-made heating apparatuses, that the amateur can get exactly what he wants without having to turn himself into a labourer. Greenhouse builders and heating experts advertise pretty regularly in the better class horticultural newspapers, some advertise in the more costly gardening books, especially those dealing with greenhouses or indoor flower and fruit culture, while very extensive lists are given in horticultural directories.

Rough Greenhouses may be erected on a basement of brick or stone work by letting a square pole in at each corner and nailing on ready-glazed frame lights, reared up along each of the four sides, fitting a door in, of course, at one end. Wood should be nailed along the top at both ends to slope down to each side, and the triangles so formed

can have a glass substitute nailed over them to keep out the weather. A beam should be nailed across the top and smaller frame lights, or indeed old disused window frames can be nailed on, their tops to the beam and their bases to the top edge of the side lights. Such structures are very useful on allotments where it does not run to buying a ready-made greenhouse.—E.

GREENHOUSE: Cold and Unheated.—This is an unsatisfactory structure, and little can be said in its favour, as so few subjects can be grown in it on account of the fact that it is not frost-proof. Perpetual flowering carnations may be grown in it successfully, also many hardy plants and a variety of alpines which require glass in winter. The hardier ferns may also be grown. Anything, however, which cannot stand a few degrees of frost is quite out of the question. For further notes on the above subjects, see articles on *Alpine House*, *Carnation: Perpetual Flowering*, *Ferns and Fern Gardening*, etc.

GREENHOUSE AND CONSERVATORY: Roses for.—See under Roses for Greenhouse and Conservatory in *Roses for All Purposes*.

GREENHOUSE FERNS.—See *Ferns and Fern Gardening*.

GREENHOUSE: Foliage Plants for.—See *Foliage Plants for All Purposes*.

GREENHOUSE HEATING. — See *Greenhouse Building and Heating*.

GREENHOUSE: Management of.

The term greenhouse is a somewhat elastic one, for it is applied equally to structures from which frost is just excluded, as to those whose winter temperature varies from 45° by night to 60° by day. If a good display of flowers is to be kept up at that season, it will be necessary to maintain some such a temperature as that just named.

Greenhouses are often erected in very ill-suited surroundings, either their position or structure, for the successful culture of plants, being at fault. As at times they are built against a high wall, it is almost impossible to grow symmetrically shaped plants, while they are frequently so lofty as to cause the occupants to draw up tall and weak. Both these disadvantages are quite commonly to be met with in the so-called conservatories attached to dwelling-houses. They are only too often death-traps for plants, rather than buildings designed for their successful culture.

The most desirable form of greenhouse is that with a span roof, as it admits of an equal distribution of light on all sides of the plants. Provision should be made for ventilation both at the top and sides. The height of the structure will, of course, depend upon the size of the plants for which it is intended, and the interior arrangements according to its width. A house 10 ft. wide may have a central path of 3 ft., and stages of 3½ ft. on either side. Structures of greater width are best with a central stage or bed, and a path around the side stages as before. Such a greenhouse allows accommodation for small plants at the sides and taller ones in the centre. The uses to which a house of this class may be put will now be dealt with under the different seasons.

The Greenhouse in Spring.—Early in the spring the chief floral display is kept up by means of bulbs of different kinds, by Carnations, Cyclamen, the most forward of the Primulas, Indian Azaleas, and various hardy plants, including shrubs that have been gently forced. Some of the shrubby Begonias too

will supply a welcome bit of colour, and to these may be added greenhouse Heaths and various other subjects. Later on come Calceolarias, Cinerarias, Hippeastrums, or Amaryllis, as they are generally called, Pelargoniums, etc.

Cultural details in the spring are many and exacting, for seeds of various kinds have to be sown, and a great number of plants need repotting at this season. Fuchsias that have been dormant all the winter will need to be trimmed into shape, and encouraged to grow by watering and occasionally syringing them. Tuberous Begonias for the summer display, with Gloxinias and Achimenes, must be started into growth, Cannas divided, and Pelargoniums put into their flowering-pots. Summer-bedding plants that have been wintered in boxes will need to be potted singly, while cuttings of various things must be put in, especially plants intended for autumn and winter blooming. In this class must be included Carnations, Chrysanthemums, Eupatoriums, Salvias, and others. This by no means exhausts the list of work to be done where a miscellaneous collection of plants is grown.

As the spring advances the sun gains power, hence it will be necessary to shade the plants that are blooming as well as young seedlings, cuttings, and all kinds of tender subjects. Different methods of shading are adopted. The glass is sometimes painted over with a preparation known as Summer Cloud, but by far the better plan is to use blinds fixed on rollers, so that they can be drawn up when not required. If left on during the winter, these blinds are of great service when let down during frosty nights. What with the brighter weather and the plants being in active growth they will need an increased amount of water. Syringing, too, on the mornings of hot days will be beneficial, provided that plants in flower are not wetted overhead. Lastly, a sharp look out must be kept for insect pests, especially aphides or green fly, which, if unchecked, make rapid headway in spring. They can be readily destroyed by vaporising with nicotine.

The Greenhouse in Summer.—At this season of the year the greenhouse will as a rule be at its very best. The masses of flowers of all kinds yield a wealth of colour that will gain the admiration of every one.

Only to mention a few, there are such well-known subjects as Begonias, especially those of the tuberous rooted section, Fuchsias, Gloxinias, Heliotropes, Lilies, Petunias, and quite a host of other flowers. Where space exists for hanging-baskets there are several summer blooming plants that are seen to great advantage treated in this way. Among them are Achimenes, drooping varieties of the tuberous-rooted Begonia, the different forms of *Campanula isophylla*, Ivy-leaved Pelargoniums, with Tropaeolums and other flowers.

With regard to cultural details at this season, the first important matter will be to provide increased accommodation for the different plants that are in full growth. Fortunately many of those that were wintered in the greenhouse may be placed outside during the summer months. It is very essential that they are well supplied with water, as plants dry quickly when outside. If they can be plunged in beds of cocoanut refuse or ashes, the risk of injury from drought will be much lessened. The space thus provided will be of great service for the growing and flowering plants. Where staking is necessary it should

be done in a quiet and unobtrusive manner, using no more ties than are absolutely necessary for the actual support of the plants. No fire heat will be required during the summer. At this season, especially if the weather is hot, the plants dry quickly. The best time to water is in the evening, as the roots of the plants have then a much longer time in which to absorb the moisture. Many of the flowering subjects will be greatly benefited by an occasional dose of some stimulant. Weak liquid manure and soot water combined is very good for the purpose, and in addition there are many plant foods now to be obtained from horticultural sundriesmen.

The Greenhouse in Autumn.—During the early part of the autumn a great many of the plants that have been flowering throughout the summer will continue their display, with others in addition. Prominent among these are the Agapanthuses, *Crinum Moorei*, *Crinum Powellii*, Nerines, and *Vallota purpurea*.

As the season advances Chrysanthemums, Eupatoriums, and Salvias will come into bloom. The different hybrids of *Begonia socotrana* are very showy too at that season. The treatment required by the plants in the greenhouse at the beginning of autumn will be much the same as in the summer. As the season advances less water and less shading will be required. The watering must then be done in the morning in order to allow time for any superabundant moisture to dry up. Should frost put in an appearance, the outdoor plants must be brought under cover. A little fire heat will at times be necessary.

The Greenhouse in Winter.—This is commonly regarded as the dull season of the year, but though the number of plants in flower is considerably less than in the summer, the greenhouse may even then be kept gay. Among the flowers are some of those mentioned in the autumn, and in addition Arum Lilies, early Indian Azaleas, Chrysanthemums, Cyclamen, Freesias, Heaths, Paper White Narcissi, Poinsettias, Primulas of sorts, Zonal Pelargoniums, and others. The bright red berries of *Solanum capsicastrum* also form a very attractive feature. The cultural requirements for the winter months are much less than at other seasons. Potting is practically at a standstill, as the roots of the plants should not be disturbed during the winter. The chief aim must be to combat the unfavourable weather so often experienced. If wet, cold, and foggy, a gentle heat in the hot-water pipes combined with a little air on the top of the structure will help to keep the atmosphere light and buoyant, conditions so needful for flowering plants. All dead flowers should be removed, as they are apt to set up decay.

Watering must be done in the morning, and care taken not to spill more water about than is absolutely necessary. In the event of severe frost the better plan is to allow the plants to be quite dry before watering them. Advantage should be taken of the blinds if there are any available. Should frost penetrate into the structure, the temperature must not be rushed up all at once, but allowed to rise gradually, the glass being meanwhile covered so that the plants are in the dark. So treated, many tender subjects will come through such an ordeal without injury.—W. T.

GREENHOUSE AND STOVE PLANTS DISLIKING LIME. — See *LIME HATERS*.

GREENHOUSE: UNHEATED.—See *GREENHOUSE: COLD AND UNHEATED*.

GREENHOUSES : CUBICAL CONTENTS OF. — See CUBICAL CONTENTS OF GREENHOUSES under VOLUMES in *ARITHMETIC AND GARDENING.*

GREENHOUSES AND FRAMES :

Types of.—No garden is complete without glass, and in the suburban garden or on the allotment it is difficult to cultivate vegetables or flowers successfully without it. Greenhouses and propagating frames can be made by the amateur, or purchased complete and ready for fixing. The best materials should be used; good 21 oz. glass, and strong metal fittings, also the best white lead paint (see article on *PAINT AND THE GARDEN*) are essential. A few of the more important types are described below :—

Cucumber Frames.—These frames, portable and of handy size, are usually sold according to the number of sliding lights they contain. These are about 4 ft. wide, the standard length being 6 ft. Thus we have a "one-light" "two-light," or "three-light" frame.

Cucumber and Tomato Houses.—Greenhouses specially constructed for growing either cucumbers or tomatoes are steep pitched; the height of the sides is about 3 ft., the ridge rising to a height of 7 ft. The base woodwork should be grooved and tongued and well made, ample provision for ventilation being, of course, allowed for. Such houses are very suitable for preserving plants and cuttings during the winter.

Forcing Frames.—Forcing frames can be made like MELON FRAMES (see below), but higher, and with glass ends if desired. They are similar to the upper part (built on brick) of a forcing pit.

Lean-to Greenhouses.—The greenhouses sold by specialists ready for fitting together are sometimes called TENANT'S LEAN-TO GREENHOUSES, in that they are tenant's fixtures and can be removed at will. Amateur carpenters can, however, erect quite good houses which answer well and add to the appearance of a garden, and are exceedingly useful. Preferably well-seasoned red deal should be used, and in building them the joints should be mortised and tenoned. There should be ventilating lights in the front and roof. The stage for plants should be of stout and ample laths, suitably spaced, with shelves or light deputy stages for small pots. Approved sizes are 8 ft., and 12 ft., by 6 ft.; also 12 ft., and 12 ft., by 7 ft.

Melon Frames. — For growing melons, three-quarter span frames are recommended. Those with two or three lights of the usual size (see CUCUMBER FRAMES above) are the best for general use. These frames are also handy for other purposes and for winter preservation of plants.

Span-roof Greenhouses. — These are tenant's fixtures, and, like lean-to greenhouses, should be made of seasoned red deal, well jointed and fitted, also glazed with 21 oz. glass. It is much better to buy these ready-made, complete for fitting together, and primed for painting. The following are all well-proportioned sizes : 8 ft. by 6 ft.; 12 ft. by 8 ft.; and 16 ft. by 10 ft.

One- and two-light border frames are also useful in a garden and answer many purposes.

Among sundry frames and lights useful for many purposes may be mentioned cup glasses, oblong lights, and seed protectors with zinc frames.

F. W. B.

GREENS : Winter and Summer.

Winter Greens include most of the members of the cabbage tribe which are planted out in June and July to stand for part or the whole

of the winter. The exceptions are found in Celery Cabbage, Couve Tronchuda, and Kohl Rabi, the leaf portion of which is used during the summer and autumn. Summer Greens consist largely of Spring Cabbages, which are planted in August in firm ground. The vegetables Spinach Beet, Perpetual Spinach, etc., though giving greenstuff both in summer and winter, do not come within the term summer and winter greens. It may be pointed out that greens are not nearly so necessary in summer as in winter, owing to the abundance of other crops from May to October, though many of us would be sorry to be without the sweet white cabbages so freely cut in June and July.

Cauliflowers, though often termed Winter Greens, do not come within the strict meaning of the term, owing to the fact that the heads find different purposes in the home to Broccoli, Brussels Sprouts, Cabbages, Kale, and so on. The term winter green used to be limited to Broccoli, Curled Greens, and Kale, but of late it has come, as we have already mentioned, to include all the members of the great Cabbage or Brassica Family with the exceptions named.

Culture of Greens.—Full details of growing greens will be found under *Borecole* for Curled Greens and Kale, and under the separate articles on the vegetables named above. Two points of special importance may be mentioned, however; first, that planting of all kinds of greens in drills is strongly advised for the dual purpose of conserving moisture and enabling more thorough earthing up; and secondly, that all greens whether for the summer or winter should be planted in firm ground, each individual plant being made very firm. This will mean the plants will stand through the winter much better, and will not grow long and leggy in the summer.

Winter Greens should never be fed with nitrogenous fertilisers after the 1st of August. Summer Greens can have weak liquid manure given them throughout the summer and will in return be of greatly improved quality.

Clubroot.—All greens are very liable to clubroot disease, and if the land is badly infected many thousands of plants will fail. The attention of all readers is drawn to the article on *Diseases of Plants* by a well-known expert, and if the suggestions contained in it under Clubroot are carefully followed, this disease, otherwise a serious menace, will be kept well in control, and in all probability completely cured.

Pests.—Greens are very liable to attacks of the Cabbage Root Fly and Maggot as well as other pests. The reader should turn to our expert's article on *Insect Pests* for the methods of control.—E. T. E.

GREVILLEA (Nat. Ord. Proteaceæ).—This is a greenhouse evergreen shrub, with ornamental foliage useful for decorative purposes. It is propagated by cuttings of well-ripened young shoots in sandy soil under a bell-glass with slight bottom heat, also by seed in spring in heat. Peat loam and sand is a suitable soil. Temperature required, 40–50° F.

Greenhouse Species.—*Grevillea Forsteri.*—Bright red trusses. Flowers in June. Height, 1–2 ft.

G. Manglesii.—Green ornamental foliage, and white flowers in May. Height, 1–2 ft.

G. Preissei.—Deep red, yellow at tip. Flowers in June. Height, 1–2 ft.

G. robusta.—Fern-like foliage, and orange flowers in June. Height, 1–4 ft.

GREY ALDER (*Alnus incana*).—See *Trees*.

"GRIDIRON" TREES.—See under Planting Distances in *Fruit Culture : Hardy*.

GRINDELIA (Gum-plant of California. Nat. Ord. Compositæ).—About twenty half-hardy and hardy biennial and perennial species of this exist, most of them being yellow flowered. They are easy plants to grow provided winter protection is given, but are not as attractive as some.

Biennial Border Species.—Two only are worthy of culture, and neither of these figure in the *Kew Hand-list*. They may be raised by sowing seed in the spring or autumn in an unheated greenhouse or frame, after which the plants are put in their permanent positions outside in May.

Grindelia ciliata.—This is a hardy yellow August-blooming plant about 1½ ft. high.

G. grandiflora.—This bears large orange or orange-yellow flowers throughout the summer, and grows 2½–4 ft. high.

Perennial Border Species.—The following may be grown in common garden soil in the ordinary manner for perennials, but slight winter protection should be afforded, and planting in cold districts deferred until late March or early April :—

Grindelia glutinosa.—This bears pretty yellow flowers in August, and grows 2–5 ft. high.

G. inuloides.—This bears yellow flowers in August, and grows 2–5 ft. high.

G. lanceolata.—This is a useful yellow sort blooming all the summer, and averaging 2 ft. in height.

G. squarrosa.—This sort bears yellow flowers in August and September, on plants 2–4 ft. high.

GRISETTE.—See Edible Fungi in *Fungi : Edible and Harmful*.

GROMWELL.—See *Lithospermum*.

GROSS-FEEDING CROPS.—See *Kinds of Crops*.

GROUND-BEETLES. — See under Beetles in *Insect Friends*.

GROUND IVY (*Nepeta Glechoma*).—See *Catmint*.

GROUND TISSUES.—See under Tissues in *Plant Physiology*.

GROUNDSEL.—A common annual weed. See *Water Garden: Plants for the*, and *Weeds*.

GROWTH.—See *Plant Physiology*.

GRYLLOTALPA.—See Mole Cricket in *Insect Pests*.

GUANO.

No sensible gardener should be blind to the benefits which result from the use of good guano. Of natural fertilisers, it is, when of good sample, as near a perfect fertiliser as one can have, but unfortunately it is often very much adulterated.

The three best kinds are Fish Guano, Native Guano, and Peruvian Guano.

Fish Guano, as its name implies, is made on the coast from waste fish. It is a powerful phosphatic fertiliser useful as a liquid manure for cucumbers, herbaceous plants (especially Sweet Peas), tomatoes, and vegetables (especially peas and beans). Two ounces of this fertiliser can safely be hoed into each square yard of ground, or the same quantity stirred up with a gallon of water applied to that area. In coast places it should be very cheap at the works and should be very largely used ; inland if Peruvian Guano can be had at the same rate Fish Guano should be left alone.

Native Guanos are not very soluble manures. They are largely made

at sewage works, and in their pure state should be a fine, dry, almost odourless powder. More care should be taken than is at present at the works to see that they contain the highest possible proportion of soluble matter. Native Guanos are rich in soluble organic matter, and sometimes are very rich in lime—it rather depends on the process of manufacture. The plant-food is not immediately available, so they can safely be used in the late winter or early spring as manure for vegetable crops. As the organic matter they contain is chiefly nitrogen, the guanos should not be used overmuch for crops which are not grown for their leaves. They can be used at the rate of 1 lb. per each square yard.

Peruvian Guano is certainly when pure by far the best of all the guanos. It is a perfect fertiliser—or as near such as we can get, for it supplies soluble nitrogen, phosphates, and a little potash. It is probably used more as a phosphatic fertiliser than as a general one, but it should always be regarded as a general fertiliser. We cannot call to mind at the present time any single plant which does not improve enormously if a little guano is applied to it.

This guano, as its name implies, comes from Peru. It is, strictly speaking, the excreta of numerous sea-birds. To test its purity, heat a weighed quantity on a shovel, as advised in the article on *Ammonia*, and if nearly half of it vanishes the sample is rich in organic matter. Shoot the remainder into water. Stir, filter, dry, and weigh. If half this has dissolved the sample is good. If practically none has dissolved shoot the dry material into 2 per cent. citric acid solution, stir, filter, dry, and weigh. If the weight is the same as before, or very nearly so, reject the sample as impure.

Peruvian Guano, though rather expensive, is when pure well worth its cost. As it is very frequently adulterated with crushed bones, normal or in some cases mineral phosphate of lime, the above test should in every case be applied. It can be used in a similar manner and in similar quantities to Fish Guano.

On the market at the present time there is a compound known as *Dissolved Guano*. This contains very little organic matter and hardly any potash; it is mostly mono-calcium orthophosphate. As it is very expensive the gardener should avoid it.

All guanos should be kept in a dry place. The organic matter they contain reacts with moisture to form soluble or gaseous nitrogen compounds, and these compounds are quickly lost by exposure. Barrels with well-fitted lids or well-covered earthenware jars are the best receptacles for storing guanos in.—E. T. E.

GUELDER ROSE (*Viburnum Opulus*). See *Shrubs*.

GUERNSEY ELM (*Ulmus campestris sarniensis*).—See *Trees*.

GUERNSEY LILIES (*Nerines*. Nat. Ord. Amaryllidaceæ).—The Guernsey Lilies are a magnificent family of bulbous plants from South Africa. They are to September and October what the Tulip is to April and May. They bear brilliant flowers with narrow recurving and frequently crinkled segments of some shade of red, salmon, pink, or white, in umbels on wiry footstalks from 15–20 ins. high. In a few varieties, as in *Lady Bromley*, a grey colour develops with age, and makes a pleasing change from the all pinks and reds. The true and

original Guernsey Lily (*Nerine sarniensis*) is very shy flowering, and as it is an old inhabitant of our greenhouses, it has given the whole family a bad name in this respect. Now, however, there is an immense change for the better, and some of the more recent hybrids flower practically every year if the essential and simple details of culture are observed. A peculiar character of the flowers is that they shine as if made of tinsel, or sparkle as if powdered with diamond dust, either in sunshine or under artificial light. Thanks to the improvements recently made by hybridists in their free flowering properties, in the extension of their range of colour, and in the size of the blooms, the race is rapidly gaining favour.

Culture.—The bulbs like a good, rich virgin loam, to which has been added some sharp silver sand and a small amount of leaf-mould. They must not be over-potted, as they flower best when pot-bound. One large bulb in a 4½-inch pot, or three bulbs in a 6-inch pot, is about right for all the varieties except the *pudica hybrids*, which do well in smaller pots. Repotting is only necessary every third or fourth year. The best time for the operation, or for buying new bulbs, is early August, just before the flower stems begin to appear. Guernsey Lilies, with the exception of *Nerine Bowdeni*, which in the Southern parts of the British Isles may be planted outside in a warm border under a south wall, are not hardy, and require the protection of a cool greenhouse during winter, with a temperature of about 45–55° F. They flower from the beginning of September to the end of November. The details of their management are as follows: As soon as the tips of the sheaths of the flower heads appear, water must be given, and later on, when they are in full flower, and the green leaves are in evidence, regular feeding is necessary. This must be continued all winter, until in May the foliage turns yellow, when water must be gradually withheld. During June and July the plants must be kept quite dry and fully exposed to the sun until once more the tips of the flower stalks appear. Their flowering depends on the care taken of the bulbs all the winter after they have flowered, and the annual summer baking. Given these, Guernsey Lilies may be counted upon to give satisfactory results. If a small greenhouse could be given up to them, so that there would be no other plants to be considered, the gorgeous sight every September, October, and November would, we think, be amply sufficient to repay the owner for his care.

Seeds are freely produced if the flowers are hand fertilised. It is important to know that they always look green and unripe. They may, however, be gathered when they naturally begin to drop off, and then they should be *thinly* sown at once in pans or pots. They germinate in from five to eight weeks. Seedlings may remain where sown for two years, when each bulb should be put in a 3-inch pot, and grown on in it until it flowers.

Species and Varieties.—*Nerine Bowdeni* has large pink flowers, and is nearly hardy. Its variety *alba* is white.

N. Epic is a bright rose-pink variety.

N. Fairy Queen has narrow petals of soft pink colour.

N. flexuosa alba is quite similar, but pure white.

N. Fothergillii major has flowers of salmon-scarlet. It is very fine, and is generally the first to flower in September.

N. Glory of Sarnia produces immense orange-scarlet flowers.

N. Lady Bromley has flowers of rosy-pink, which develop lines of slate colour with age. It is very effective.

N. Lady Carrington is a pale rose and white sort.

N. Lady de Walden is a bright rose.

N. Lady Mary Shelley produces clear pink flowers and is very free blooming.

N. Manselli is a late flowering rosy-pink variety, blooming in November.

N. Meadowbank bears large orange-red flowers.

N. Miss Willmott is a fine glowing scarlet.

N. Mrs H. J. Elwes produces delicate pink flowers with deeper colour at the base of the petals.

N. Mrs Hooker bears rose and white flowers.

N. Rosebud has white flowers which pass into deep rose.

N. Rotherside bears fine orange-salmon flowers.

N. sarniensis is the original Guernsey Lily with rose flowers. It is a shy bloomer.

N. sarniensis corusca is an attractive scarlet.

N. undulata (Syn. *N. crispa*) has narrow petals and rosy or pink flowers.

All the above flower in September, October, or November, according to the temperature of the house in which they are growing, and average 15–20 ins. in height.

J. J. & E. T. E.

NEW VARIETIES.

Nerine Esconia has large carmine pink flowers, and *N. Vivia* is fiery scarlet.

GUINEA CORN.—See *SORGHUM*.

GUINEA-FOWL MANURE. — See *POULTRY MANURE*.

GUINEA WHEAT (*Zea Mays*).—See *ZEA*.

GUM.—See *EXHIBITORS' GUM*.

GUM CISTUS (*Cistus ladaniferus*).—See *SHRUBS*.

GUM-PLANT OF CALIFORNIA.—See *GRINDELIA*.

GUM TRAGACANTH (*Astragalus massiliensis*).—See *ASTRAGALUS*. See also *Astragalus Tragacantha* in *SHRUBS*.

GUM TREE.—The genus EUCALYPTUS. See *TREES*.

GUM TREE: AUSTRALIAN. — See *EUCALYPTUS*.

GUMMING OF FRUIT TREES.—See under GUMMOSIS in *DISEASES OF PLANTS*.

GUMMOSIS. — See *DISEASES OF PLANTS*.

GUNNERA (Nat. Ord. Haloragineaceæ).—This is a genus of striking foliage perennials, the flowers of which are small and of little value. Culture is easy, as they thrive in a good ordinary garden loam provided this can be kept reasonably moist. As they are not quite hardy in cold districts, a mound of leaf-soil, cocoanut fibre refuse, or even coke ashes over their rootstock from November to February is advisable. They are best propagated by root division in the usual way, but may also be raised by summer sown seeds.

What to Grow.—A large number of species have been described, and of these we cordially recommend the following:—*Gunnera bracteata, G. chilensis* (Syn. *G. scabra*), *G. densiflora, G. magellanica* (Syn. *G. falklandica*), *G. manicata, G. monoica*, and *G. perpensa*. The *Gunnera maculata* of nurserymen is probably a corruption of the name *G. manicata*. The height of these plants averages 2–6 ft.

GYMNADERIA.—Now included in the genus HABENARIA.

GYMNOGRAMME. — For the best species and varieties see *FERNS AND FERN GARDENING*.

GYMNOTRIX.—Now included in the genus *Pennisetum*.

GYNANDRIRIS.—Now included in the genus *Iris*.

GYNERIUM (Nat. Ord. Gramineæ). This genus has now been united with *Cortaderia* (which see) by the Kew authorities. The only species of any importance is *G. argenteum*, now *C. argentea*, the well-known Pampas Grass, which is retained under the first name in our article on *Ornamental Grasses*, as this name is so much better known and much more generally used.

GYPSOPHILA (Chalk Plant. Nat. Ord. Caryophyllaceæ).—There are several useful hardy annuals in this genus of elegant plants, and their slender stems and lightly poised flowers make them very popular where cut flowers are in much request for home decoration. Where there is a great demand for the latter purpose and for marketing, sowings should be made in autumn and in early and late spring in moderately good soil. Thin sowing is desirable if the plants are grown in borders or beds, for effect, and some slender twiggy Birch branches should be placed among them to prevent damage by wind or rain. Thicker sowing in rows 6–12 ins. apart will suffice if the plants are to be cut for decorating.

Annual Species.—Below we briefly describe the best :—

Gypsophila elegans.—A white species flowering in the spring, summer, and autumn, according to time of sowing seeds. There is a pink variety *G. e. rosea*, and a large-flowered strain of the type is sometimes offered as *G. e. grandiflora*. Height, 15–18 ins.

G. muralis (Syns. *G. agrestis, arvensis, purpurea*, and *serotina*).—A pink summer flowering sort useful in the rock garden. Height, 6 ins.

Perennial Border Species.—These are useful light growing garden plants, thriving in ordinary light loam containing lime. They are easily propagated by division of the roots in the autumn or spring. We recommend the following :—

Gypsophila acutifolia.—This is a white July flowering species about 1 yd. high.

G. arenaria.—A synonym of *G. fastigiata*, which see.

G. collina.—Syn. *G. fastigiata.*

G. fastigiata (Syns. *G. arenaria*, and *G. collina*).—A white June flowering species about 1½ ft. high.

G. grandiflora.—This is a white June-blooming sort growing about 2 ft. high.

G. paniculata.—Probably this is the most popular of all hardy perennial Gypsophilas. Its white flowers borne in July, August, and September are most useful for cutting. The plant averages 1 yd. in height. The double variety *G. p. flora plena* is quite as useful as the single form.

G. perfoliata.—This bears bright reddish flowers from July onwards, and averages 2 ft. high.

G. prostrata.—This is a deservedly popular sort for edging purposes. It bears attractive little red flowers from August onwards, and averages about 9 ins. in height.

G. repens.—This, described under rock garden species, is also useful for edging purposes in perennial borders.

G. tenuifolia.—This bears red flowers from July onwards, and averages 12 ins. in height.

Rock Garden Species.—These are light graceful perennials and thrive in light sandy loam with limestone added. They are propagated by division of the roots in the autumn or spring. We recommend the following :—

Gypsophila cerastioides.—This is one of the dwarfest, and of tufted habit. Flowers white with red

veins. Site open. Flowering Period, May to September. Height, 3 ins.

G. repens.—This has prostrate stems. Flowers white in sprays. Site sunny. Flowering Period, June to September. Height, 3 ins. Its variety *rosea* has pink flowers.

G. transsylvanica.—This plant has tufted growth and leaves. Flowers whitish, in heads. Site sunny. Flowering Period, June to July. Height, 3 ins.

GYPSUM.

Gypsum is hydrated sulphate of lime ($CaSO_4 . 2H_2O$). Its uses in the garden are somewhat limited, but worth recognising. Its chief value on the land itself is as a purifier, and if the rich and frequently sour soil of an old garden which has been heavily manured with dung for years be dressed with Gypsum alone for a season at the rate of 4–8 oz. per sq. yard, a vast improvement will be seen in the crops. Apply in the autumn and early winter.

Gypsum has also another use, namely, for "fixing" ammonia in dung heaps. This property is also possessed by Kainit and certain other potash manures, but a very large quantity has to be used. That is not so in the case of Gypsum. The crushed material is sprinkled fairly thickly over the outside surface of the heaps (not mixed with it as is so often advised), and then fixation takes place.

Gypsum is found in several artificial fertilisers, notably superphosphate of lime, and dissolved bones. Its presence there is accounted for by the use of sulphuric acid to reduce the tri-calcium orthophosphate of which bones and coprolites largely consist, into soluble mono-calcium orthophosphate. As it is only very sparingly soluble in water, its use is greatly limited, but still it should not be wholly overlooked.—E.

GYPSY WORT, or GIPSY WORT.—See *LYCOPUS.*

H

HAAST'S DAISY BUSH (*Olearia Haastii*).—See *CLIMBING AND TRAILING PLANTS.*

HABENARIA.—See *ORCHIDS.*

HABERLEA (Nat. Ord. Gesneraceæ).

A genus of tufted plants with leaves in rosettes, suitable for growing in the shady parts of the rock garden in rocky crevices. They are propagated by division of the crowns in the autumn or spring. Only one species is usually grown.

Haberlea rhodopensis. — Leaves deep green, with corrugated edges. Flowers lilac, with pale yellow throat, tubular. Site shady. Soil sandy peat. Flowering Period, June to July. Height, 4–5 ins. Varieties of this are *H. Ferdinandi Coburgi*, with larger flowers and lighter green leaves, and *H. virginalis*, with pure white flowers.

HABRANTHUS (Nat. Ord. Amaryllidaceæ).—Although now referred by botanists to the genus Hippeastrum, in gardens Habranthus is still retained as a separate genus, and *H. pratensis* is grown as a half-hardy or greenhouse bulb to some extent. It is not of difficult culture, thriving in ordinary light loamy soil in a temperature of 65–75° F. Several forms are available, with cream-yellow, dark red, and scarlet and yellow flowers. The plant blooms in May, and grows about 12 ins. high.

HACKBERRY (*Celtis occidentalis*).—See *TREES.*

HACQUETIA (Syn. *Dondia.* Nat. Ord. Umbelliferæ).—A curious and pretty spring-flowering rock plant. It is propagated by division of the roots in autumn or spring, and thrives in a moist half-shady position. The most desirable species is :—

Hacquetia Epipactis.—Very dwarf. Flowers yellow, in umbels surrounded by yellow-green leaves. Flowering Period, March to April. Height, 3 ins.

HAILSHAMBERRY.—See *BRAMBLES AND BERRIES.*

HARDENING OFF.

The immense importance of thoroughly hardening plants off before they are planted out in their permanent position is not fully realised by gardeners. Hence we see bedded out borders spoilt because the plants have by cold been suddenly checked, whereas, if they had been gradually inured to the weather, no drooping and no losses would result.

For hardening off, cold frames or open-work frames are indispensable. First of all, the boxes of seedlings, cuttings, or the pots of plants, should be transferred from a warmer to a colder part of the greenhouse, and given any amount of air; after a week or two of this they should about the middle of May be transferred to frames without heat for a fortnight, these frames being left more and more open each night, except when there is actual frost; and finally they should be put into open-work frames, which are really framelights supported on wooden poles, for a few days. The air and wind will thus play all round them.

Plants so treated get gradually used to their changed surroundings, and can be safely planted out in the flower borders in June without the least fear of a check due to cold resulting. (See also *BEDDING OUT: PRACTICAL HINTS ON.*)

Hardening off is equally important in the case of vegetable plants raised in the greenhouse for outdoor work. Neglect of it may mean that the crops thus sown do not reach maturity until after those sown out of doors, for a sudden change of temperature will throw them back many weeks as regards growth.—E. T. E.

HARDY FLOWERS FOR CITY GARDENS.—See *TOWN AND CITY GARDENING*.

HARDY FRUIT CULTURE.—See *FRUIT CULTURE, HARDY: GENERAL CONSIDERATIONS*.

HARDY ORANGE.—A name applied to the genus ÆGLE. See *SHRUBS*.

HARDY ORCHIDS.

There are many beautiful Hardy Orchids which may be grown in gardens, either in half-shady portions of the rock garden, or in the fern border where such members of the family as the Lady's Slipper (*Cypripedium*) and others will thrive. The different genera, of which there are over twenty, are found growing all over Europe. Many are also found native in England. In the present work it is only proposed to deal with those that are fairly easy to grow, omitting altogether those of smaller value from a garden point of view.

Cypripedium.—This is a large family popularly known as the LADY'S SLIPPER ORCHIDS and contains many fine plants. Most of

them thrive in well-drained soil rich in humus, but others, such as *C. Calceolus* and *C. macranthum*, prefer a loamy soil of a calcareous nature. All prefer half-shady situations, amongst other low-growing plants. The best species are :—

C. acaule.—Syn. *C. humile*, which see.

C. Calceolus.—This bears brown and yellow flowers from May to June, and grows about 18 ins. high.

C. californicum.—This is a smaller plant with yellow petals and white lip spotted with brown. It blooms from May to June, and grows about 9–12 ins. high.

C. candidum.—This in general habit is like the above, but with white flowers.

C. hirsutum.—Syn. *C. parviflorum*, which see.

C. humile (Syn. *C. acaule*).—This bears large rosy-purple flowers in May, on plants 3–6 ins. high.

C. macranthum.—This is a strong handsome species bearing large rich purple-rose flowers in May. It grows nearly 2 ft. high.

C. montanum.—This species bears brownish-purple and white flowers in May and June, three or more flowers on each stem, and is nearly 1 ft. high.

C. parviflorum (Syn. *C. hirsutum*).—This bears brown, purple, and yellow flowers in May, on stems up to 2 ft. high.

C. pubescens.—This is similar to the above but with larger flowers of yellowish-brown and yellow colour also in May.

C. spectabile (Syn. *C. Reginæ*).—This is one of the finest sorts with large white flowers shaded with rose on the lip. It blooms in June, and grows about 2 ft. high.

Epipactis.—This is a small family of which two species may be selected as worth growing. They like a strong loamy soil, but the latter prefers the moister situation.

E. gigantea.—This bears yellowish-brown and red flowers in May and June, and grows about 1 ft. high.

E. palustris.—This is a free growing sort with brown and white flowers in June, on stems about 1 ft. high.

Orchis.—This is a very large family and contains many beautiful kinds. They all grow freely in moist loamy soil. The following are the best :—

O. foliosa.—This, the MADEIRA ORCHIS, bears long spikes of rosy-purple flowers in May, and grows 1½ ft. high.

O. latifolia.—This, the MARSH ORCHIS, is a strong-growing native species with spikes of pale purple spotted flowers in early summer. Forms of this often grow over 2 ft. high.

O. maculata.—This, the SPOTTED ORCHIS, is another native species with spotted leaves and spikes of flowers varying in colour from bright purple to white. It flowers in May, and grows 1 ft. high.

Other Hardy Orchids which may be easily grown include the BUTTERFLY ORCHIS (*Habenaria bifolia*), with yellow and white flowers ; the BEE ORCHIS (*Orchis apifera*), with velvety-brown flowers ; the TWAYBLADE (*Listera ovata*), with green flowers ; and the LIZARD ORCHIS (*Orchis hircina*), with greenish-yellow long-tailed ones. The one known as LADIES' TRESSES (*Spiranthes autumnalis*), with spikes of white flowers, should also be grown if space admits.—W. I.

HARDY PERENNIALS.—See *PERENNIALS : GENERAL CULTURE OF.*

HARDY PLANTS FOR EDGING.—See *EDGING : HARDY PLANTS FOR.*

HARE-BELL (*Campanula rotundifolia*).—See *CAMPANULA.*

HARE'S EAR.—A name applied to the genus BUPLEURUM. See *SHRUBS*.

HARE'S FOOT FERN (*Davallia canariensis*).—See *FERNS AND FERN GARDENING*.

HARE'S FOOT TREFOIL (*Trifolium arvense*).—See *TRIFOLIUM*.

HARE'S LETTUCE (*Sonchus oleraceus*).—See *SONCHUS*.

HARE'S TAIL GRASS (*Lagurus ovatus*). See *ORNAMENTAL GRASSES*.

HARICOT BEAN.—See *PHASEOLUS*.

HARMFUL FUNGI.—See *FUNGI: EDIBLE AND HARMFUL*.

HARPALIUM.—Now included in the genus HELIANTHUS.

HART'S ELDER (*Sambucus racemosa*).—See *TREES*.

HARTSHORN PLANTAIN (*Plantago Coronopus*).—See *PLANTAGO*.

HARTSTONGUE FERN (*Scolopendrium vulgare*).—See *FERNS AND FERN GARDENING*.

HARVESTING VEGETABLES.—See *VEGETABLES: HARVESTING AND STORING*.

HARVESTING VIOLETS.—See *VIOLETS*.

HASSOCK GRASS (*Carex paniculata*). See *CAREX*.

HAUTBOIS (*Fragaria elatior*).—See *FRAGARIA*.

HAWKBIT (*Leontodon*. Nat. Ord. Compositæ).—A very large number of Hawkbits have been described, and nearly a dozen are grown at Kew. All are weedy, hardy herbaceous perennials of no garden value, and thus we do not propose to devote space to describing them here.

HAWKWEED (*Hieracium*. Nat. Ord. Compositæ).—The Hawkweeds are among the coarser growing hardy perennials, and while they are as a rule excluded from the choicer borders, they are none the less useful in the rougher parts of the rock garden, in the shrub border, and in the wild garden. The dwarfer sorts are best for the herbaceous border or rock border. They succeed in sun or light shade, in common garden soil, and are propagated in the usual way by seeds sown in the summer, or by division of the plants in the autumn or spring. They may be successfully planted any time from October to March.

What to Grow.—A very large number of species have been described and are frequently included in Horticultural Dictionaries. We confine our attention, however, to the few described below, which we cordially recommend:—

Hieracium alpinum.—This is a pretty yellow-flowered subject for edging or rock garden, blooming in July. It grows 6 ins. high.

H. anglicum is very similar to *H. alpinum.*

H. aurantiacum.—This is an attractive species bearing bright orange flowers in June and July. Its height is about 2 ft.

H. Bommuelleri.—This is a useful sort bearing vivid yellow flowers from June to August, and growing 1 ft. high.

H. Pilosella (MOUSE-EAR HAWKWEED).—This is a weedy creeping yellow June-blooming sort of no value for the borders. [It may, however, be grown in the wild garden.—EDITOR.] Its height is 6 ins.

H. villosum.—This is the best sort of all for herbaceous borders. It bears yellow flowers in July, and averages 1–2 ft. in height.

HAWTHORN (*Crataegus Oxyacantha*). See *TREES*.

HAY-SCENTED BUCKLER FERN (*Nephrodium æmulum*).—See *FERNS AND FERN GARDENING*.

HEATHER.—See ERICA in *HEATHS*, also CALLUNA in *SHRUBS*.

HEATHS.

There are a considerable number of varieties of the heather cultivated in gardens, and when planted in suitable spots these provide in their season a source of infinite delight. Heathers find an ideal place in the foreground of collections of larger growing plants such as Azaleas, Gaultherias, and Rhododendrons. The vigorous growing kinds furnish an added charm to woodland scenery, and all of them, especially the smaller ones, make excellent rockwork plants. Heather gardens are becoming more and more popular every season, as the plants furnish their flowers all the year round. At least twenty different kinds may be grown in ordinary garden soil without any peat whatever; and the secret of preserving the life of heathers grown in gardens is to prune immediately after the flowering period, which is a lengthy one.

Propagation.—This may be carried out by seeds, cuttings, or by layering. The latter is the surest way of quick production. A good mixture of peat and loamy soil should be placed liberally around the plant, and the centre filled up, at the same time bending and spreading the growth out from the centre. Some good-sized stones placed on the growths will hold them down. Layers will take from nine to twelve months to root, and in the month of September the growth can be cut off from the parent plant with safety.

Uses of Heaths.—Many and varied are the uses to which heaths are put, though these are in many cases confined to the Highlands: the hardy Scotch, for instance, thatch their cottages with heather, and very often they make their beds of the same material, avowing that they are much more comfortable and healthy than the feather beds of the effeminate lowlanders. A considerable trade is carried on each year in making brooms and scrubbing-brushes from heather. From time immemorial dyes have been extracted from some species; these, mostly green and yellow, being used in the manufacture of tartan cloth. Herbalists find many uses for decoctions, etc., of heather against tumours, gout, dysentery, and scurvy, while mountain cattle are frequently fed on the tender tops of the heather, and this diet is said to yield very sweet meat.

Varieties of Heaths.—The heathers which flourish so luxuriantly on the mountains of England and Scotland are *Calluna vulgaris* and *Erica Tetralix*, the CROSS-LEAVED HEATH. Those who have visited the Lake District in August and September in the valley of Easdale, Grasmere, of Wordsworth fame, or the slopes of Scawfell and Skiddaw in Cumberland, will have cause to remember the glorious picture of heather when the sun is setting, casting its lights and shadows at eventide.

We give below a selection of the best varieties for garden purposes. A very large number have been described, and to attempt to give a complete list here would be quite beyond the scope of the present

work. Most of the varieties are highly useful in the rock garden as well as in the heath garden or heath border.

CALLUNA VULGARIS (Syn. *Erica vulgaris*).—This is the COMMON LING, and is the only species in the genus. It is a low-growing shrubby plant of which there are numerous varieties. The flowers of this type are purple. All varieties succeed in ordinary sandy loam or peat, and flower from August to October.

The following are distinct varieties :—

Alba.—The COMMON WHITE HEATHER. Height, 9–12 ins.

Alporti.—The best crimson form. Height, 15 ins.

Argentea.—A sort with silver-tipped foliage. Height, 12 ins.

Aurea.—An attractive variety with golden-tinted foliage. Height, 12 ins.

Flore pleno.—The DOUBLE-FLOWERED HEATHER. Height, 12 ins.

Hammondi.—A pure white sort. Height, 18 ins.

Searlii.—A pure white sort. Height, 9 ins.

DABOËCIA POLIFOLIA (Syn. *Menziesia polifolia*).—This is the ST DABEOC'S HEATH and produces purple bells of flowers in spikes. It succeeds in a half-shady site and moist peaty soil, flowering from July to October. Its height is 12–18 ins. *D. p. alba* has white flowers, while *D. p. atropurpurea* produces purple-crimson bells.

ERICA (HEATHER. Nat. Ord. Ericaceæ).—This is a large family of dwarf shrubby plants which all flourish in sandy loam or peaty soil, except *Erica carnea* which likes a calcareous soil. The following species are nearly all hardy :—

E. arborea (TREE HEATH).—Hardy only in the south. Flowers white, fragrant. Flowering Period, March to May. Height, 6 ft. *E. a. alpina* is a hardy form of this species.

E. australis.—Flowers rosy-purple, fragrant. Flowering Period, March to May. Height, 2–3 ft.

E. carnea (ALPINE FOREST HEATH).—Flowers pink. Site partly shaded. Soil, limestone. Flowering Period, January to April. Height, 4–6 ins.

E. ciliaris (DORSET HEATH).—Flowers large pale purple bells. Flowering Period, June to October. Height, 1 ft.

E. ciliaris mawiana is larger in all its parts and deeper in colour. The variety *alba* has white flowers.

E. cinerea (SCOTCH HEATH).—Flowers purple. Flowering Period, July to October. Height, 9 ins. The variety *alba* has white flowers, and *coccinea* has bright crimson ones.

E. lusitanica (PORTUGUESE HEATH).—Flowers white in long sprays. Flowering Period, December to April. Height, 3 ft.

E. mediterranea.—Flowers pale pink. Flowering Period, March to May. Height, 2–5 ft. *E. m. alba* has white flowers, while *E. m. hybrida* is a dwarfer form, with deep pink flowers blooming in January.

E. stricta (CORSICAN HEATH).—Flowers pale pink. Flowering Period, June to July. Height, 2–3 ft.

E. Tetralix (MARSH HEATHER [1]).—Flowers rosy-purple. Site open. Soil moist peaty. Flowering Period, August to October. Height, 1 ft. *E. Tetralix Mackaii* is a variety with flowers rose coloured on the sunny side and almost white on the other.

E. vagans (CORNISH HEATH).—Flowers purple. Flowering Period, July to October. Height, 18 ins. *E. vagans alba* has white flowers.

E. Veitchii.—Flowers white.

[1] The CROSS-LEAVED HEATH of Kew. —EDITOR.

Flowering Period, February to April. Height, 3 ft.

E. Watsoni.—Flowers bright purplish-pink. Flowering Period, July to September Height, 1 ft.

T. R. H. & W. I.

HEAVY SOILS: VEGETABLES FOR.—See *VEGETABLES: GENERAL CONSIDERATIONS.*

HEBERSTRETIA.—See *ANNUALS, HALF-HARDY: LIST OF.*

HEDERA.—For the best species see *CLIMBING AND TRAILING PLANTS.*

HEDGE HYSSOP.—See *GRATIOLA.*

HEDGE MUSTARD.—See *SISYMBRIUM.*

HEDGE STRAW (*Galium Mollugo*).—See *GALIUM.*

HEDGEHOG.

Gardeners often regard this as an enemy and destroy it, or banish it from the garden. This is a great mistake. It feeds chiefly on harmful insects, and while it may also eat a few earthworms, it should certainly be regarded as a friend and not an enemy.

HEDGEHOG CACTUS (*Echinocactus Simpsonii*).—See *CACTI.*

HEDGEHOG FUNGUS.—See URCHIN-OF-THE-WOODS under EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

HEDGES.—See *GARDEN HEDGES.*

HEDGES: ROSES FOR.—See ROSES FOR HEDGES in *ROSES FOR ALL PURPOSES.*

HEDYPNOIS.—Now included in the genus LEONTODON.

HEDYSARUM (Nat. Ord. Leguminosæ).—This genus is not largely grown, but it includes some pretty plants for the borders and rock garden, so it should not be wholly neglected.

Biennial Border Species.—These require the usual treatment for hardy biennials and may be successfully raised from seed sown in the early summer, the young stock either being wintered in a frame or in a sheltered bed outside. Only two species are generally grown.

Hedysarum coronarium (FRENCH HONEYSUCKLE).—This bears attractive scarlet flowers from June to August, and grows about 1½ yds. high.

H. pallidum.—This is a rose and pale red sort blooming about June, and growing 1½ ft. high.

Perennial Border Species.—These succeed if given the usual treatment for perennials. They should be planted in March in open sunny borders in ordinary loam of moderate quality, and may be propagated by division of the roots in February and March. There are a large number of sorts, of which we recommend the following:—

Hedysarum capitatum.—This is a rose-coloured sort blooming in June and July, and growing about 2 ft. high.

H. microcalyx.—This is an attractive species bearing bright purple flowers in June, and growing about 1½ ft. or more high.

H. polymorphum.—This useful rose-flowered June blooming sort grows about 12 ins. high.

H. sibiricum.—In this we have another purple sort bearing pretty

flowers in June, and growing about 1½ ft. high.

Rock Garden Species.—Only three need be named here; these, however, are pretty covering plants, and well worth growing :—

Hedysarum boreale.—This is a pretty sort. Flowers purple. Site sunny and among rocks. Soil light rich loam. Flowering Period, June to July. Height, 6 ins.

H. neglectum.—This is useful for the rougher parts of the rock garden. Flowers purplish. Site sunny. Soil ordinary loam. Flowering Period, June to July. Height, 1½–2 ft.

H. obscurum (Syn. *H. alpinum*).—This is a pretty little plant with erect stems. Flowers purple. Site sunny. Soil light rich loam. Flowering Period, July to August. Height, 6 ins.

See also SHRUBS.

HELENA.—Now included in the genus *NARCISSUS*.

HELENIUM (SNEEZEWORT, etc. Nat. Ord. Compositæ).—This is a genus of extremely useful hardy perennial plants for herbaceous borders and shrubbery margins. They are highly valuable for cutting, very showy in the border, and easy to cultivate.

Culture.—The plants can be grown without difficulty in a good ordinary garden soil in a sunny site, and may be planted any time between November and March. When division is necessary this may be done at the same period. The taller varieties need early staking, but little feeding and watering is necessary. They may easily be raised from seed sown in March or June. Seed may also be saved with little difficulty from the earlier flowering sorts.

What to Grow.—There are a large number of excellent sorts to choose from. We recommend the following :—

H. autumnale.—This is one of the most popular species which flowers all the late summer and autumn. There are many varieties of it, such as *compactum bicolor* (yellow and crimson); *cupreum* (crimson and gold); *grandiflorum* (yellow with darker coloured centre); *magnificum* (rich golden-yellow); *praecose* (clear yellow); *striatum* (bright orange-yellow); and *superbum* (golden-yellow). The height averages about 3–4½ ft. See also *H. pumilum*.

H. Bigolovii.—A late flowering species with yellow flowers. Height about 4 ft.

H. Bolanderi.—A fine sort which should be very largely grown. The flowers are yellow and produced from July onwards. Height about 1½–2 ft.

H. grandiflorum (or *H. grandicephalum* of the nurseryman).—Some authorities refer this and *H. pumilum* to *H. autumnale* and to *Inula grandiflora*. It has large yellow flowers, blooms from July to August, and averages about 4–5½ ft. in height.

H. Hoopesii.—A useful kind with bright yellow flowers, sometimes orange-yellow. It blooms from June to September, and is 2½ ft. high.

H. nudiflorum.—A synonym of *H. autumnale*, which see.

H. pumilum.—This popular so-called species of which there are many varieties is now considered synonymous with *H. autumnale*. Thus the sort *magnificum* (rich golden-yellow), so freely described in trade lists, should be *H. autumnale magnificum*, and the varieties known as *Riverton Beauty* and *Riverton Gem* (yellow and red) should be classed as forms of *H. autumnale*, and not as varieties of *H. pumilum*. The flowering period extends from July to November, and the height ranges from 2½–5 ft.

HELIANTHEMUM (SUN ROSE. Nat. Ord. Cistaceæ).—A genus of sub-shrubby plants suitable for sunny banks and old walls in the rock garden. They are propagated by cuttings in autumn, or by seeds sown in spring. Four species are desirable :—

Helianthemum canum.—A prostrate species. Leaves silvery. Flowers bright yellow. Site sunny. Soil sandy loam. Flowering Period, all the summer. Height, 2 ins.

H. italicum var. *oelandicum.*—Also prostrate. Flowers deep yellow. Site sunny. Soil sandy loam. Flowering Period, June to July. Height, 3 ins.

H. Tuberaria.—This has tufted growth. Leaves large. Flowers yellow, in umbels. Site sunny. Soil sandy loam, well drained. Flowering Period, June to July. Height, 6 ins.

H. vulgare.—This is more or less prostrate. Flowers many colours, orange, pink, red, rose, and yellow. Site sunny, in rock border or wall garden. Soil sandy loam, with lime in it. Flowering Period, June to August. Height, 4–12 ins., according to variety.—W. I.

See also *SHRUBS*.

HELIANTHUS.—See *SUNFLOWER*.

HELICHRYSUM (EVERLASTING FLOWER. Nat. Ord. Compositæ).—Apart from the well-known *H. bracteatum*, which is dealt with in our article on *EVERLASTING FLOWERS*, there are some few species of trailing or tufted habit suitable for the rock garden. They may be propagated by division in the spring or by means of cuttings in July. We recommend the two following :—

H. bellidioides.—This is a creeping plant. Flowers white in heads. Site open and sunny. Soil well-drained gritty loam. Flowering Period, July to September. Height, 4 ins.

H. frigidum.[1]—This is a small tufted plant. Flowers white in heads. Site open and sunny. Soil gritty loam in a rocky crevice. Flowering Period, July to September. Height, 3 ins.

See also *EVERLASTING FLOWERS*.

HELICIDÆ.—See SLUGS AND SNAILS in *INSECT PESTS*.

HELIOPHILA.—See *CAPE STOCK*.

HELIOPSIS (ORANGE SUNFLOWER. Nat. Ord. Compositæ).—This attractive little genus of hardy herbaceous perennials is somewhat neglected, but it is distinctly useful for the back of the perennial border, shrub border, or the wild garden. The plants succeed in ordinary good rich garden soil in a sunny site, and are easily propagated by seed in the usual way or by division of the root-stock in the autumn or spring, at which times they may be successfully planted. Only two species are grown at Kew ; these are briefly described below :—

Heliopsis laevis.—This bears yellow or orange flowers in August and September, and averages about 2 yds. in height.

H. scabra.—This bears yellow flowers from August onwards, and both single and double forms are available. Its variety *pitcheriana* bears bright orange flowers and is the most attractive. The height averages 2–4½ ft.

HELIOSPERMA.—Now included in the genus *SILENE*.

HELIOTROPE.—The generic name is now *HELIOTROPIUM*.

HELIOTROPIUM[2] (CHERRY PIE. Nat. Ord. Boraginaceæ).—This is a free flowering, soft-wooded ever-

[1] This is not quite hardy, and must be covered with glass to keep it through the winter.—EDITOR.

[2] The botanical name used to be *HELIOTROPE*.—EDITOR.

green shrub, with slightly scented flowers, and is useful for greenhouse culture or summer bedding. It is propagated by cuttings in spring and autumn in slight bottom heat, and should be grown in light rich soil. Temperature required in winter, 40° F.

Greenhouse Varieties.—*Heliotropium Madame Braunt.* — Mauve. Flowers from May to September. Height, 1–3 ft.

H. Paul Pfitzer.—Light flower, blooming from May to September. Height, 1–3 ft.

H. President Garfield. — Mauve. Flowers from May to September. Height, 1–3 ft.

H. Priapo.—Blue, with white eye. Flowers from May to September. Height, 1–3 ft.

H. Roi des Noirs.—Deep maroon-purple. Flowers from May to September. Height, 1–3 ft.

H. White Lady.—Nearly white. Flowers from May to September. Height, 1–3 ft.

New Variety.

Heliotropium Mrs J. W. Lowther. —This bears dark purple flowers in large trusses, and is very fragrant.

HELIPTERUM. — See *ANNUALS, HALF-HARDY: LIST OF.*

HELIX.—See under SLUGS AND SNAILS in *INSECT PESTS.*

HELLEBORE SPRAY.—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION.*

HELLEBORUS (BEARSFOOT. Nat. Ord. Ranunculaceæ).—Quite delightful hardy herbaceous perennials are all the species of this genus, except perhaps *H. foetidus.* As a rule they are exceedingly easy to grow, thriving well in light moist soil in a shady margin to the shrub border, or an easterly aspect in the perennial border. They are easily propagated by seeds sown in the usual way in the spring or summer, and are not difficult to increase by division of the roots in the spring (March), which is also the most suitable time to plant. Some of them, notably the CHRISTMAS ROSE (see *Helleborus niger* below), are useful for cutting, and all are showy plants for the border. As the plants are poisonous, children should not be allowed to touch them. The following is a representative selection :—

Helleborus antiquorum.—This is a white March blooming sort, growing 1½ ft. high.

H. caucasicus.—This bears greenish flowers in the spring, and averages 1½ ft. in height.

H. colchicus.—This useful sort bears full-coloured purple flowers in February, and grows 1½ ft. high.

H. foetidus (STINKING HELLEBORE) —This is the least desirable of all, with its strong, unpleasant smelling greenish flowers in March. It grows 18 ins. high.

H. niger (BLACK HELLEBORE and CHRISTMAS ROSE).—This is probably the most largely grown of all, and is a great favourite with its white flowers in February and March on plants 1 ft. high. Various varieties of it are offered by the trade, pinks, purples, and whites, or at times prettily spotted, and of similar height, the best of which are: *altifolius* (often in bloom earlier than February), *angustifolius*, *praecox*, and *Riverstoni.*

H. orientalis (Syns. *H. officinalis* and *H. ponticus*).—This sort and its variety *roseus* are popularly known as LENTEN ROSES. Their flowers are exceptionally lovely, and the named varieties, of which there are not a few, include a wide colour range from pale purple, dark purple, rosy-purple, and crimson-purple, through shades of pink to a crimson spotted white. All flower freely

from February onwards, and average 1–2 ft. in height.

H. viridis.—Of the numerous greenish varieties of this offered for sale and grown at Kew, only one is in our opinion really worth growing. This, *H. v. purpurascens,* bears rich purple flowers with but little green in them from March onwards, and averages 1½ ft. in height. Another plant named *H. viridis* is now referred to *H. caucasicus,* which see.

HELONIAS.—See *STUD FLOWER.*

HELOSCIADIUM.—Now included in the genus *APIUM.*

HELVEL. — See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

HEMEROCALLIS (DAY LILY. Nat. Ord. Liliaceæ).—This is an attractive genus of beautiful hardy herbaceous perennial plants worthy of more extensive cultivation. They are very useful for herbaceous, mixed, or strictly perennial borders, and may be used in the water garden. (See remarks on DAY LILY in our article on *WATER GARDEN: PLANTS FOR THE.*)

Culture.—This is a very simple matter indeed, if ordinary light loam on the moist side is provided. Success may be attained with the usual (somewhat haphazard) culture bestowed on other hardy perennials, though the taller sorts need, it is true, careful staking. Propagation is best effected by root division in March, which month is also the best planting period.

What to Grow.—Some of the species previously classed in this genus are now included in other genera, such as Funkia and Lilium. Only a few of the best species and hybrids can be included here on account of restricted space :—

Hemerocallis aurantiaca.—This and its variety *major* are deservedly two of the most popular sorts. They bear brilliant orange or deep orange-yellow flowers from June to September, and average 1½–3 ft. in height.

H. disticha.—Syn. *H. fulva,* which see.

H. Dumortierii (Syn. *H. rutilans*). —This and its variety *Sieboldii* bear orange-yellow and orange-pink flowers respectively from July to August, and average 1½ ft. in height.

H. flava.—This bears yellow flowers in June, and grows 2 ft. in height.

H. fulva (Syn. *H. disticha*).—This and its varieties *Kwanso* and *variegata* bear coppery coloured flowers from July to August, and grow about 1 yd. in height.

H. graminea.—Syn. *H. minor,* which see.

H. hybrida.—Under this head we include a few of the best hybrid forms. *Apricot* is typical apricot-colour; *Aureole* is dark orange; *Dr Regel* is deep apricot; *Gold Dust* is a lovely rich gold; *Orangeman* is, as its name implies, a first-class orange; *Queen of May* is an early sort with yellow flowers; *Sir Michael Foster* is deep yellow; and *Sovereign* is bright orange-yellow. These bloom profusely from June onwards, averaging 2–3 ft. in height.

H. luteola.—This is a most useful species bearing golden-yellow to orange-yellow blooms from June to August, and averaging 3–4 ft. in height.

H. Middendorffii.—This and its variety *major* bear yellow or orange-yellow blooms in July and August, while their height averages 2–4 ft.

H. minor (Syn. *H. graminea* and *H. pumila*).—This is the dwarfest of all and bears golden-yellow flowers from August to October, only growing 12 ins. high.

H. rutilans.—Syn. *H. Dumortierii,* which see.

H. Thunbergii.—This bears dark yellow blooms from June to August, and grows about 2 ft. high.

NEW VARIETY.

Hemerocallis Golden Bell.—This is a rich yellow large-flowered sort of great merit.

HEMIDICTYUM.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING.*

HEMILEPIS.—Now included in the genus LEONTODON.

HEMLOCK.—See *CONIUM* and *MEDICINAL HERBS.*

HEMLOCK FIR.—A name applied to the genus TSUGA. See *TREES.*

HEMLOCK SPRUCE (*Tsuga canadensis*).—See *TREES.*

HEMP AGRIMONY.—See *EUPATORIUM.*

HEMP NETTLE.—See *GALEOPSIS.*

HEN AND CHICKENS (*Sempervivum globiferum*).—See *SEMPERVIVUM.*

HENBANE.—See *HYOSCYAMUS* and *MEDICINAL HERBS.*

HENINGIA.—Now included in the genus *EREMURUS.*

HEPATICA.—Now included in the genus *ANEMONE,* which see.

HEPIALUS.—See GARDEN SWIFT MOTH in *INSECT PESTS.*

HERACLEUM (Cow PARSNIP. Nat. Ord. Umbelliferæ).—Most of the Cow Parsnips are a great deal too coarse in habit to be worthy of a place in the flower borders. They are, however, distinctly useful for shrub borders, the water garden, or in the wild garden, where they may be grown in almost every kind of soil with little care. The perennials may be propagated without difficulty by root division, and any species by seeds at the usual times, and may be successfully planted in open weather throughout the winter.

Biennial Species.—The following may be included if space permit, all of which produce white flowers in May and June: *H. asperum* (3–4 ft.); *H. pyrenaicum* (3 ft.); *H. Sphondylium,* the coarse growing HOGWEED (4–5 ft.); and *H. villosum* (4–12 ft.).

Perennial Species.—These are preferable to the above biennials. All those named below bear white flowers from June to September: *H. lanatum* (4 ft.); *H. Leichtlinii* (5–6 ft.); *H. nepalense* (4–6 ft.); *H. Panaces,* popularly known as HERCULES ALL-HEAL (4–6 ft.); *H. persicum* (10–14 ft.); and *H. Wallichii* (4–6 ft.).

HERB CHRISTOPHER.—See *ACTAEA.*

HERB FRANKINCENSE (*Laserpitium latifolium*).—See *LASERPITIUM.*

HERB GARDENING.

Herb Growing and Herb Gardening are two different matters—that must be realised to start with. Herbs can *grow* anyhow, best of all in their natural condition, but Herb Gardening is a trained science and requires, moreover, a knowing eye to trade, to bear on the process.

The first point is to decide on what you are going to expend your gardening care and knowledge, and this depends on what you mean to cater for: whether you decide to supply the druggists, or to grow your herbs to meet the needs of some branch of industry or trade. You will find your choice must be greatly governed by the soil and situation of your land: what you can grow successfully depends on whether your soil is either wet, medium or moist, or dry and well drained; and whether the situation is sunny and open, or shaded. If you raise for culinary uses, most of the herbs utilised for this thrive in light, dry, limy, or chalky soils and in open positions, the fullest and most delicate flavours coming through sunlight. Again, the greatest percentage of oils and fatty substances produced in plants required in industrial trades, and also the majority of plants useful both to the herbalist and

in the veterinary sphere, are obtained from herbs grown on light soils. Druggists' plants, on the other hand, such as Aconite, Valerian, etc., lean more to damp soil, favouring moisture. It is no good trying to cultivate for profit plants to which your soil is unsuited.

As regards general methods of cultivation, in light soil herbs need little or no "cultivation," they "grow splendidly": given open space and unlimited sunlight and the roughest weeds being kept down, they will luxuriate, being real children of Nature. Some of the druggists' plants like, too, to live their days in peace—in quiet woods and watery meadows, following their own sweet will, developing into fat, luscious creatures, needing no care, only the freedom to live and spread, the bees and other insects doing their natural duties of fertilising without human interference, thus effecting the setting of seeds and propagation. Such are, for instance, the Comfrey, the Hemlock, Meadow Saffron, Sweet Flag, etc.

In growing for trade, you have to aim at attaining in the plants the growth and state in which they will yield their highest percentage of medicinal values, technically called "alkaloids." There are many points to be paid attention to before you have learnt your lesson in that branch of the subject; for example, Foxgloves yield their best medicine from wild plants, not from those brought into the garden and cultivated, or fussed with manurial doses of medicine of various sorts: if you bring them farmyard droppings or potash got from burnt refuse, they will not thank you for it—it will only make them sickly. The best and most valuable medicinal juices are often to be got from the wild children of the hedges and ditches, growing anyhow and anywhere.

Of course, some valuable herbs like the Belladonna, for instance, will, however, need special food and special care and attention to produce their best, and their cultivation must be carefully studied and carried out, always though with a view to giving them as far as possible their natural conditions as regards soil and situation.

The propagation of your stock is a point of very practical importance. You must know how to increase it from year to year with the least expense, and must learn in which cases this is to be done by cuttings, when by division of roots, and when by seeds only. Some seeds, you should remember, require to be sown the minute they are ripe, others in the following spring only. Cuttings are best taken in spring-time: put down a line, dig a sharp little trench and then lay in your cutting (which must not have borne flower but be slightly ripened, and not too juicy or succulent); if the soil be heavy, put a little sand or a little mortar rubbish in the trench first, but not if the soil be light. Earth up to the leaves of the cuttings and tread firmly in the ground, to let the cuttings "bite" it a little, and make them "callus" quicker. Give a little shade and water for a few days (an inverted flower-pot will often meet the latter case) until the leaves begin to freshen—a sign that rooting has commenced and the cuttings started to grow, but do not attempt to hurry the cuttings.

Now to the last stage—harvesting of our herb crops, whether for cookery or medicine. You must cut your herb when the sap is flowing strongest and fastest, just

as it is about to open its blue or pink eyes in bloom. If it is the root alone you are going to harvest, you must, however, never let the plant bloom and run to seed—all its essence and strength must be driven into its root production by keeping its bloom cropped off, even before it forms a flowering head. You may perhaps be wanting to grow for seed: remember then this point, your most fertile seeds come from your earliest and fattest blooms, and you must gather them just at the auspicious moment, in brightest sun, when newly, fully ripe, and when once gathered, you must never allow seeds to get damp, even for a moment.

But your work is not yet over. After harvesting, there still remains the important process of drying and preparation for market, before the produce can obtain a saleable value, but space forbids me to enter fully into the details, which vary according as the whole plant, or only the leaves, the flowers, seeds, roots, or bark is the part that is to be used in medicine or trade.

Even in such a brief account, enough has been said, however, to indicate that "Herb Growing" and "Herb Gardening," besides being a pleasant and attractive occupation, is one in which success, as in everything else worth doing, depends entirely on proper understanding of herbs themselves, and for notes on individual herbs the reader should refer to the separate articles upon them.—M. G.

HERB GROWING.—For hints on this see *Herb Gardening, Medicinal Herbs,* and *Potherbs.*

HERB LILY.—See *Alstroemeria.*

HERB PARIS.—See *Paris.*

HERBACEOUS BORDERS: Making New.—The making of new herbaceous borders is probably one of the very pleasant tasks the gardener has to do. He sees a dull worn-out shrubbery which never has pleased and never will please his master and mistress, and makes the suggestion that it should be transformed into an herbaceous border full of glorious colour. The suggestion is agreed with, and the gardener sallies forth to begin.

He feels as he looks over the expanse of ground that he has taken on what may well be a Herculean task. How shall he begin, and how shall he finish, these are two questions he asks himself.

Clearing the Land.—It is no good doing the border in bits. The present writer has seen such a thing attempted, and while the start may be brilliant, before the border is half-done the gardener will find himself in a muddle and wish himself out of it. By far the best way is to clear the whole of the ground first, scrapping all the shrubs which are no use, and re-planting elsewhere those which are of some slight value. The surface of the ground being clear, it should be forked over to remove stones and roots.

Preparation of the Soil.—The next thing to do is to dig thoroughly, or better still to trench the whole of the plot. The writer considers trenching of enormous importance in the first instance, and wherever possible it should be carried out. During the trenching, which should be done if possible in September for autumn planting, or December and January for spring planting, plenty of manure should be mixed in with the bottom two spits of soil, and a good layer put at the bottom of the top spit. Basic slag or bonemeal can be freely mixed with the top spit of soil, also burnt ashes from the garden bonfire, and these three materials will mightily improve it.

In trenching the soil for the border,

care should be taken not to bring any of the sour subsoil up to the top. Lime and basic slag should be mixed freely with the subsoil, though they should not come into direct contact with the manure. Cow and pig dung are best for soils of a sandy nature, and horse manure and rotted vegetable refuse (excluding such a binding material as lawn mowings) for a soil that is heavy.

The bed so trenched should have at least a month to settle, and our next consideration is :—

Planting.—Much has been written in the Press on the advantages and disadvantages of autumn planting. The present writer, working as he does in a very cold exposed district where icy winds and snow blow straight from the moors, is of the opinion that spring planting is preferable in every way to early autumn planting, since the flowers have a far smaller check when planted then, than when planted just at the beginning of what may be a very severe winter. But in warmer southern districts where plants bloom freely out of doors in late December and early January, he would strongly urge on gardeners the wisdom of early winter or autumn planting, since there is absolutely no doubt that much finer plants, earlier and better flowers, as well as much more bloom can be produced that way when the climatic conditions are such that the plants do not feel the cold. For early blooming plants such as Anchusas, Doronicums, Lupines, Paeonies, etc., autumn planting is specially desirable ; spring planting producing later blooms of much smaller and poorer quality.

The planting itself is fairly easy in the case of ordinary clumps, but difficult in the case of such plants as perennial Anchusas, Lupines, Sunflowers, etc., possessed of long tap or forked roots. In the case of ordinary clumps, holes into which they will just comfortably fit are taken out with the spade. The holes must not be made deeper than the soil level on the clumps, for if the clumps are buried deeper than before, some of the crowns may rot off. In the case of tap-rooted plants very deep holes must be dug, the roots spread out so that they are not in the least doubled or twisted, and the soil filled in very carefully.

In both cases make the plants very firm. Firm planting is, the writer considers, one of the chief secrets of success. In any case the plants will be loosened by the frost, so the firmer they can be made when planting, the better for them. No plants can be expected to take root in new soil unless it is made reasonably firm round them—a fact wholly overlooked by very many gardeners. After planting, a stick should be put in to mark the places in case the visible portion of the crowns should rot off. The ground should then be lightly raked over to give it a neat finished appearance.

Arrangement of Plants. — More than usual care should be taken in the arrangement of the plants. Ignorance of the habit and nature of the plants will produce some queer effects the following season—a fact many gardeners do not realise at the time. Careless, haphazard arrangement is not worthy of any one who proudly calls himself a gardener. Before starting to plant, the gardener should have a clear idea in his mind what the effect both in colour and form will be, and he should make certain that such is the best arrangement he can manage, otherwise planting will be waste of precious time.

Much has been written on arrangement of plants. Some people adhere slavishly to having the plants set

in strict order of their height. This, the writer considers, is one of the biggest possible mistakes, producing as it does a very dull and often "prim" effect. Artistic visitors will say when they see such a border, that too much care has been bestowed upon it. Such a border would have found favour a hundred years ago; then primness, and stern adherence to general principles, was the rule.

It is now, however, greatly preferable not to consider the question of height so much. The border now in the course of construction is to be as fresh and bright as possible. The wish is that it shall be full of little surprises; some charming plant here where we least expected it, and some more farther on. Great blocks of tall plants near the front are, of course, out of place, but small ridges of the nobler plants coming near to it, and effectively concealing the rest of the border from view, are most desirable. Friends should never be encouraged to stand at one end of the border and look right down it with a view to praising it as a whole: the border should be arranged in such a manner that it is impossible to see the whole of its charms without walking from end to end. To secure this, it is desirable to have a winding path; and the ideal, where the area for the border is a large one, is to have herbaceous borders on both sides of the winding path. The path should be arranged so as to wind gracefully in and out among the flowers; then at every corner a new picture will be seen.

As regards colours many gardeners produce a ghastly effect by putting clashing colours side by side. For instance, they will put purple side by side with light blue, yellow beside scarlet, and red against violet. The effect when the plants are in bloom is not only hideous, but highly irritating to the eyes of all who are not affected with colour blindness, and such borders reflect discredit not only on the gardener who made them, but on his master and mistress to whom they belong. Before planting, the gardener should jot down the respective positions of the various colours, on paper, and ask himself if they will clash. If he cannot tell he should submit them to some artist who can. It is impossible to give full details here.

Several colours can be produced by mixing other colours together. These are what are termed mixed, or compounded colours, as distinct from simple or primary colours. A good rule for avoiding clashing mixed colours is found in a definition culled from a recently published book,[1] to the effect that "when a compounded colour contains more of one colour than another, it tends to clash with the colour which is present in the lowest proportion." This statement has been amply proved in practice, and gardeners would do well to commit it to memory.

The arrangement should be such that there are great splashes of colour. Little bits of colour are not worth much, indeed they hardly show at all, but great splashes of colour, produced by planting plenty of plants of one kind or one colour together, are worth walking miles to see. It is thus that gardeners realise the vast beauty of Nature, and such masses of glorious colour make us feel that it is worth living to be a gardener.

Lastly, the border should be so arranged that it is never without some plant of each separate colour in bloom. Its first glory will doubt-

[1] *Jottings of a Gentleman Gardener.*

less be in the early spring with early Anchusas, Anemones, Doronicums, and Irises. But this display must be immediately followed by that from summer blooming plants, late Anchusas, Delphiniums, Erigerons, Inulas, Lupines, Paeonies, Valerians, and many more. To succeed these must be the late summer-blooming plants, *Chrysanthemum maximum*, late Delphiniums, late Inulas, early Sunflowers, Thalictrums, and so on. And these must finally be succeeded by the autumn-blooming plants, such as Border Chrysanthemums, Michaelmas Daisies, Rudbeckias, perennial Sunflowers, and many more. With a little thought and care an herbaceous border will be a picture of glorious colour from 1st April to 1st November, and such a picture is worth producing.—E.

HERBACEOUS BORDERS: Management of, and General Considerations.—Having made and planted the herbaceous border, the next consideration is its management. A border perfect in every way at the start can soon be completely spoilt if it is not managed properly, or if it is neglected at any period of the season. Neglect is frequent; in some cases owing to pressure of other work it is almost inevitable, but very strenuous efforts should be made to give it attention at the proper times.

Winter Management.—At this time of the year the work on the border will be light. It will consist chiefly of refirming the plants after frost, protecting the less hardy roots, such as aquilegias, pentstemons, etc., with mounds of ashes, or cocoanut fibre, and, lastly, of slaying slugs and other garden pests. This last is of vast importance, and even more so in the late winter and early spring when all the plants are just starting to grow. Some soil fumigant should be lightly forked into the ground in February, and slug traps laid on the surface, also the very choicest plants may be protected by means of zinc rings. In the case of existing borders, the wooden labels of the plants, unless they are very large and durable, will need renewing every season, and the winter is undoubtedly the best time for doing the work. Labels which are not brittle or rotten may be scraped, repainted, and rewritten. Any which are inclined to rot should be scrapped and replaced by new ones, for they are cheap enough.

Spring Management.—The spring will bring a busy time upon the herbaceous gardener. He will see his perennials springing up, and with them up will come a multitude of weeds. Slugs and snails will become very busy too; they eat their Christmas dinners not until the spring, but then they make the most of their time if allowed to do so. No one would mind if they would devour the weeds; gardeners would regard them as friends instead of enemies in that case, but no. They leave the weeds to us, and attack with all their strength some of our very best plants. The writer has found they are specially fond of young pyrethrums and anchusas, so extra care of these plants should be taken.

As soon as the plants have grown enough to see properly where they are, the gardener should most certainly bring out the Dutch hoe and go really thoroughly through the border with it, following this immediately with the rake to remove the weeds. During the second week in April annuals can be sown to fill up gaps caused by loss of plants. Good, bright annuals for this purpose include such as *Calendula grandiflora*, Godetias of the dwarfer sorts, *Phacelia campanularia*,

annual Chrysanthemums, dwarf annual Sunflowers, and many more. In the late spring the border should be well hoed again and the choicer subjects mulched with manure or rotted lawn mowings. This will keep the moisture in.

Summer Management.—This is undoubtedly the most important of all the seasons as regards the herbaceous border. Plants will be flowering very freely indeed, and every possible effort to continue their blooming period as long as possible should be made. First of all comes the matter of staking, and it should, as our contributor in his article on *Stakes and Staking* says, be done before the plants really need it. The great thing to avoid in staking is a bunched appearance of the plant, or conversely a forest-like appearance of the border on account of using too many sticks. Stakes of very varied size and strength will be needed, and the stake should err on the side of being over-strong rather than over-flimsy. Staking is, however, fully dealt with in the article just mentioned, and readers are asked to refer to it for further particulars. After staking comes the question of soil cultivation to conserve moisture. The free use of the Dutch hoe will do very much to attain this end, and will keep weeds down as well. But by midsummer the border, if planted with a view to splashes of colour, will be getting thick, and the use of the ordinary hoe will be difficult. When working amongst the plants, staking and tying them,—and this will have to be done at frequent intervals throughout the summer,—a small weeding fork will be found extremely useful for lifting stubborn weeds and freshening up the trodden surface of the soil. At the same time, old mulches, if dried up, can be removed and fresh ones substituted. Watering is of enormous importance if the border is to be kept gay, and should be done regularly three times a week in ordinary dry weather and every evening in exceptionally dry times. It will be a great advantage to the plants if they are lightly syringed over after 6 p.m. at least once a week in dry weather; this will do more to freshen them up than much feeding would do. The writer is not impressed with the great importance of feeding herbaceous plants, for he has seen it so often grossly overdone. Moderate feeding is, of course, highly desirable, but who in these twentieth-century days is content to feed anything moderately? Over-feeding produces rank, sappy growth, and very few flowers; it is an evil to be avoided. *Feeding Plants* is dealt with in a special article of that title, to which the reader is referred.

There are few gardeners who, when they have produced a fine border picture, like cutting the flowers off the plants, and thus spoiling that picture. These gardeners need not be blamed, for it is hard indeed to expect them to agree without demur to such a thing. When flowers are wanted for the house they can, as a rule, however, be obtained in sufficient quantity from the border in the summer-time without spoiling its effect. But in cases where there is an exceptional demand for cut flowers the gardener should provide for this by sowing or planting reserve beds. This is mentioned in the special article on *Reserve Garden*. However, if the flowers are not freely cut from the herbaceous border while they are fresh, they should most certainly be cut off the moment they are dead or withering. Nothing spoils a border so much as a few dead or dying flowers. The gardener will have to keep a constant eye on his plants, in

fact, he should never walk down the path between the borders without his knife or his clippers. A snip here and a snap there will greatly improve the look of his border, and timely removal of dead flowers frequently induces the plants to produce more in their effort to perpetuate their genus—a fact frequently overlooked, but of which full advantage should be taken. The writer once took the trouble to compile a list of plants (both annual and perennial), to which the "cut and come again" system may be applied. The list filled more than half a column of one of the gardening papers, and no space for it can be afforded here. Finally, the gardener should most carefully scrutinise his plants throughout the summer for the appearance of any plant diseases, and if they are noticed he should apply at once the remedies given under the diseases in this Dictionary. It is a case of being in time. A timely syringing with liver of sulphur may save the whole lot of plants.

Autumn Management.—This may partly be said to be a continuation of summer management to which we have given rather detailed attention. As gales may be expected in the autumn, the gardener should, early in September, go very carefully over the plants in his border and make firm all stakes, renewing and adding to the ties if necessary. Otherwise a border which might be a lovely sight for a further six or eight weeks may easily be ruined in a single night. Weeds should be pulled up by hand, and the gardener should never pass a weed which is flowering without pulling it up. Dead leaves which blow from trees into the border should also be removed, and the greatest care taken to give the border a neat and orderly appearance. Dead flowers should be taken off regularly at least twice a week, and when the plant growth starts to turn very dry and brown, cut it neatly down to 3 ins. from the ground, and clear the rubbish right away. Never leave heaps of rubbish lying about in the border in the early autumn, for nothing looks worse. Finally, right at the end of the season, cut all the plants down with a sharp knife to within 2–3 ins. of the ground, marking their places with a small flower stick, and clearing the rubbish away to give the border a neat, quiet appearance.

GENERAL CONSIDERATIONS.

The Best Site.—In laying out pleasure-grounds or gardens there is very often considerable choice of sites for herbaceous borders. The choice of a suitable site is an important point if the border plants are to do their best, and undoubtedly a border facing due south, despite its heat in summer, is the best. If possible, some arrangement for shelter from cold north and east winds should be made, for these play havoc with the plants. A garden hedge comes in useful here. Where there is a choice of soil, preference should be given to a loam which is on the light side, since many plants do far better in a light loam than in a very heavy clay soil.

Dividing the Plants.—When a border was made as advised in the last article, all the care it will need as regards plant food in the winter is to have some good rotted manure forked into it between the plants each November or February. Great care must be taken when using the fork to refrain from breaking the roots of the plants or bringing them to the surface, and the crowns should not be covered with manure, but with ashes or cocoanut fibre as protection. After three or four years of this treatment the plants will have grown so thick that it will

be highly desirable, not to say essential, to lift the whole lot and divide and replant them. The present writer considers that this work is best done in February, or very early March, but in warmer southern localities it is safe and indeed preferable to do it in October or November. The clumps of perennials are lifted with as much soil adhering to their roots as possible, and laid-in in some convenient spot not far away. (The labels should, of course, be firmly tied on to them before lifting.) Then the border can be thoroughly retrenched, plenty of manure, lime, and basic slag being worked into the lower spits, and bones, slag, and bonfire ashes into the top spit, as described in the last article. The clumps are then divided by means of a sharp spade, and the stronger outer parts replanted. In the case of tall, bushy plants the clumps should be 2 ft. apart, but the smaller clumps need only be set 1 ft. asunder or even less.—E.

HETERODERA.—See KNOT ROOT in *INSECT PESTS*.

HEUCHERA (ALUM ROOT. Nat. Ord. Saxifragaceæ).—This genus is one of which hybridists are very fond, for there are hosts of named sorts offered by the trade. The list of varieties is ever on the increase, and the already lovely flowers are yearly being improved. It is essentially a plant for the herbaceous border, though some of the more startling hybrids, such as *Crimson Spray* (see under *H. hybrida* below), look well when given beds to themselves. All the species and varieties described below are quite hardy, and all are perennials, succeeding in ordinary rich soil in a sunny site. They are easily propagated by seeds sown in the usual way in the spring or summer in light soil, or by division of the roots in the autumn or spring, at which times they may be successfully planted, and lovers of floral effects on the tables in the house should note that most of them, especially the named hybrids, are grand for cutting. Only a selection of the very best can be given here on account of limited space.

H. americana.—This bears purple flowers in May and June, and grows 12 ins. high.

H. brizoides.—Of this there are many varieties. Three of the best are *Flambeau* (pink or rose); *gracillima* (rosy-crimson); and *Profusion* (lovely white). All bloom very freely from June to August, and average 1½–2½ ft. high.

H. glabra.—This is a very pretty pink May flowering sort, growing 12 ins. high.

H. hispida (Syn. *H. Richardsoni*).—This, known as the SATIN LEAF, bears flowers which are veined with purple in May. It is a sort chiefly grown for its foliage, about 1 yd. high.

H. hybrida.—The sort known to, and sold by nurserymen, under this name, bears flowers ranging through flesh tint, and coral red to carmine. It blooms from June to August, and grows 1½–2½ ft. high. There are many other delightful hybrids flowering as freely and of similar height, such as *Crimson Spray* (bright crimson); *Kilnfield White* (pure white); *Lady Salmon* (lovely coral red or deep pink); *La Perle* (white with rose blush); *Mrs H. C. Baker* (large part white); *Nancy Perry* (bright pink); *Pink Profusion* (glorious pink); *Pluie de Feu* (fiery red); *Rosamunde* (pink); *Rosea* (pink); *Rosy Gem* (pale rose); *Rubis* (bright scarlet); and *Salmon Queen* (lovely pale rose-pink).

H. sanguinea.—This species is often a shy bloomer, but bears bright almost flame-red flowers from June onwards, and averages 1½–2 ft. high. There are many excellent varieties of it flowering about the same time and averaging the same height, for instance *alba* is white, *gigantea* is a large crimson sort, *grandiflora* is similar, *robusta* is also similar, *Shirley* is a bright coral red, and *Walker's Variety* is a very large crimson and a much freer flowered sort.

HOES.—See *GARDEN TOOLS.*

HOG'S FENNEL.—See *PEUCEDANUM.*

HOGWEED (*Heracleum sphondylium*). See *HERACLEUM.*

HOLCUS (Soft Grass. Nat. Ord. Gramineæ).—This is a genus of unattractive, easily grown, hardy perennial grasses only suitable for the wild garden. *H. lanatus* and *H. mollis* are the two best known species, and grow 2–3 ft. in height.

HOLLY (*Ilex*. Nat. Ord. Aquifoliaceæ).—Apart from its use for Christmas decoration, Holly is a splendid garden shrub which should be planted more freely than it is. It makes a dense impenetrable hedge where its sharp prickly leaves dropped at pruning-time are no disadvantage, and where it is not used to separate garden from meadow it may well be applied for the purpose of separating one portion of the pleasure grounds from another.

Holly is not a shrub of difficult culture, as it thrives in all kinds of soil. Usually it is an inexpensive shrub, as the majority of nurserymen stock it in some of its numerous varieties and readily quote the price per dozen or per hundred. The best time for planting is a matter of opinion, but we favour autumn planting rather than March planting on account of the trees being able to become more firmly established before new growth commences.

For hedge work, of course, Holly must be pruned in the summer-time, and it is advisable to use sécateurs for the work instead of shears to prevent disfigurement of the leaves. Where Holly bushes are planted for other than hedge purposes, cutting may be done, of course, at the favourite time for cutting, namely, about the 25th December. It may be noted also that Holly clippings burn readily when dry and are useful to add to slow-going garden fires.

Varieties.—An enormous number of varieties of Holly are now on the market and we cannot do more than mention some of the best. The selection below, therefore, contains only the cream of the varieties. The letter *D* indicates that the variety is deciduous, while *E* indicates that it is evergreen :—

Ilex ambigua (*E*). Height, 3–5 ft.

I. Amelanchier (*E*). Height, 10–40 ft.

I. Aquifolium (*E*). Common Holly. Height, 10–40 ft.

The following are good forms :—*albo-lineata, angustifolia variegata, argentea longifolia, argentea medio-picta* (Silver Milkmaid) ; *argentea pendula* (Perry's Weeping Holly) ; *argentea regina* (Silver Queen Holly) ; *aurea angustifolia, aurea medio-picta* (Gold Milkmaid) ; *aurea pendula* (Waterer's Gold Weeping Holly) ; *aurea regina* (Golden Queen Holly) ; *ferox* (Hedgehog Holly) ; *flavescens* (Moonlight) ; *handsworthensis* (Handsworth New Silver Holly) ; *heterophylla, latifolia aureo-marginata, lawsoniana, lawsoniana aureo-picta, marginata, myrtiflora aurea, myrtifolia, pendula, recurva, watereriana,* and *Wilsonii*. Height, 6–20 ft.

I. Cassine (*E*). Cassena. Height, 12 ft.

I. decidua (*D*). Height, 10–30 ft.

I. dipyrena (*E*). Himalayan Holly. Height, 12 ft.

I. glabra (*E*). Inkberry. Height, 2–3 ft.

I. latifolia (*E*). Toraia. Height, 20 ft.

I. opaca (*E*). American Holly. Height, 20–40 ft.

I. verticillata (*E*). Black Alder or Winterberry. Height, 6 ft.

HOLLY FERN (*Aspidium Lonchitis*).—See *Ferns and Fern Gardening*.

HOLLY-LEAVED OSMANTHUS (*Osmanthus Aquifolium*). — See *Climbing and Trailing Plants*.

HOLLY OAK.—The same as Holm Oak.

HOLLYHOCK (Nat. Ord. Malvaceæ).

Hardy perennials, 8–10 ft. high, succeeding in a strong loam which must be particularly well drained and freely manured. They are propagated by cuttings, division, grafting, and by seed.

Culture.—Though truly perennial in habit, the Hollyhock has become so liable to attacks of the well-known fungus (*Puccinia malvacea*) that many growers now treat it as a biennial, propagating solely from seed. This should be sown in May or June, either in a frame or the open border. Before the young seedlings get crowded, they should be pricked out into a prepared bed, and, when well established, transplanted to their permanent quarters. If seed is sown in heat in January and the plants kept growing on without a check, many of them will bloom the same year. If the perpetuation of any special sort is desired, grafting is probably the best method. A thick piece of root is cut into pieces about 2 ins. long, and into these are inserted the young growths, which shoot from the base of the old plant in spring. The growths chosen should be 3–4 ins. long, and if potted into 5-inch pots with the soil just covering the union, they will soon form strong plants capable of flowering the same year. Or the young growths may be taken from the old plants in the spring as cuttings, and rooted in light sandy soil.

Uses.—Hollyhocks answer a similar purpose in garden decoration to the Delphinium, but flower later, namely, in August and September.

Varieties.—Prior to 1870 many societies were in existence fostering the Hollyhock as a florists' flower, and named varieties, of which there was a wide selection, were exceedingly popular. Shortly after that date, the fungus appeared, and created such havoc in practically all gardens where the plants were cultivated, that a reaction set in, and the Hollyhock lost, to a great extent, its status amongst florists. Now that seed-raised plants are so commonly sold, the named varieties have practically disappeared, but the different colours come fairly true from seed.—J. L. G.

New Varieties.

The two following are well worth growing:—

Hollyhock Lady Bailey.—This has soft salmon-pink very double flowers, in compact spikes.

H. Queen of the Yellows.—This has clear yellow double flowers, and wavy petals.

See also *Althaea* and *Medicinal Herbs.*

HOLLYHOCK RUST.—See *Diseases of Plants.*

HOLM OAK (*Quercus Ilex*).—See *Trees.*

HOLY GRASS (*Hierochloë borealis.* Nat. Ord. Gramineæ).—This is a useful species of hardy perennial grass for the wild garden, growing about 1 ft. high. It succeeds in almost any soil, and is easily propagated by autumn root division or spring sown seeds.

HOLY THISTLE.—See *Medicinal Herbs.*

HOME-MADE LAWN SAND.—See *Lawn Sand.*

HOME TESTING OF SEEDS.—See *Seed Testing.*

HONESTY (*Lunaria annua*, Syn. *L. biennis.* Nat. Ord. Cruciferæ).—This well-known and favourite biennial plant, with its lilac, purple, or white flowers in May, June, and July, is valued chiefly for its silvery seed pods, which are dried in the same way as everlastings for house decoration in winter. It is easily raised from seeds sown any time during April, May, or June in the

open garden or half-shady places. The plants are transferred in the autumn to their flowering positions, and when the soil is fairly rich often grow 3 ft. high.

A plant known as PERENNIAL HONESTY (*L. rediviva*) is sometimes grown, but it is not so ornamental as the species named above. It is a herbaceous perennial bearing pale purple scented flowers in June and July, on plants about 1 yd. in height, and requires no special culture.—J.F.

HONEY BALM (*Melittis Melissophyllum*).—See *MELITTIS*.

HONEY BEE.—See *BEES IN THE GARDEN*.

HONEY-DEW.

This is a sweet fluid secreted by aphides and scale insects. It is found very commonly on the surface of hops, lime trees, roses, and may occur wherever these pests are allowed to flourish, though it is produced more freely by certain species of aphis than others. Honey-dew serves as a nourishment both to ants and to certain fungi such as Capnodium, and Fumago. These fungi are themselves non-parasitic, but they form a thin crust over the leaf which has, as a result, a black sooty appearance, and the plants suffer through the loss of light. In the case of lime trees, the honey-dew is apparently distributed by the addition of moisture from the air, as a thin varnish over the entire surface of the leaf.

REMEDY. — The application of suitable insecticides to control the aphis and scale insect.—A. D. C.

HONEY LOCUST (*Gleditschia triacanthos*).—See *TREES*.

HONEYSUCKLE.—The genus LONICERA. See *SHRUBS*.

HONEYWORT.—See *CERINTHE* and *TRINIA*.

HONKENYA.—Now included in the genus *ARENARIA*.

HOOF PARINGS.—See ORGANIC PRODUCTS under NITROGENOUS MANURES in *MANURES*.

HOOKERA.—Now included in the genus *BRODIAEA*.

HOOP-PETTICOAT DAFFODIL (*Narcissus Bulbocodium*).—See *NARCISSUS SPECIES*.

HOP CLOVER (*Trifolium agrarium*).—See *TRIFOLIUM*.

HOP HORNBEAM. — The genus OSTRYA and *O. carpinifolia*. See *TREES*.

HOP PLANT (*Humulus Lupulus*).—See *HUMULUS*.

HOP TREFOIL (*Trifolium procumbens*).—See *TRIFOLIUM*.

HOPLOCAMPA.—See APPLE SAWFLY in *INSECT PESTS*.

HORDEUM (BARLEY. Nat. Ord. Gramineæ).—This genus of grasses is of more use to farmers than gardeners. *H. vulgare* (Syns. *H. hexastichon* and *H. Zeocriton*) is the best known species; it is the common BARLEY of the fields, from which that curiously tasteless liquid BARLEY WATER is obtained. *H. murinum* is the BARLEY GRASS. The only species of any garden interest to us is *H. maritimum*, popularly called the SQUIRREL-TAILGRASS. This is briefly described in our article on *ORNAMENTAL GRASSES*.

HORMINIUM (PYRENEAN DEAD NETTLE. Nat. Ord. Labiatæ).—Only one species of this is worth growing in gardens. This (*H. pyrenacium*) succeeds in a hot dry portion of the perennial border, and is propagated in the usual way by division of the plant in the autumn or early winter, and by seeds sown in the summer. It is a blue midsummer flowering plant which grows about 12 ins. high.

HORN SHAVINGS. — See "Hoof Parings" in notes on ORGANIC PRODUCTS under NITROGENOUS MANURES in *MANURES*.

HORNBEAM.—A name applied to the genus CARPINUS, and more especially to *C. Betulus*. See *TREES*.

HORNED POPPY (*Glaucium flavum*. Nat. Ord. Papaveraceæ).—The sea-green leaves of this hardy biennial are striking, and the bright yellow flowers produced from June to August, on plants 1–2 ft. high, are very showy. It is of easy culture in any good garden soil, and may be raised by sowing seeds in the open during April or May, after which it is well to transplant the seedlings to their permanent positions when they have made a rough leaf or two.

HORNED RAMPION (*Phyteuma*. Nat. Ord. Campanulaceæ).—According to the Kew Authorities the name HORNED RAMPION is limited to *Phyteuma Halleri*, but in the garden the whole of the genus is popularly known by this name, and not by that of RAMPION bestowed upon it by the Kew and other writers, since, to call it by that name would lead to it being confused with the vegetable *RAMPION* (*Campanula Rapunculus*), on which a separate article is devoted. There are a large number of species, but the genus is of no great importance and has not come very much to the fore. Propagation by seed sown in the summer, or by division of the roots in the autumn or spring, is not difficult, and planting may be successfully carried out from November to March, in any ordinary light rich garden soil.

Perennial Border Species.—We describe a few of the best below :—

Phyteuma Balbisii.—This is a useful white sort for edging purposes. It blooms from June throughout the summer, and grows about 6 ins. high.

P. canescens (Syn. *P. salignum*).—This sort bears lilac blue flowers in June or July, and averages about 1½ ft. high.

P. Carestiae.—Syn. *P. humile*, which see.

P. Halleri (Syn. *P. urticifolium*).—This attractive sort useful for edgings bears dark violet-blue flowers from May onwards, and grows 6 ins. high.

P. humile (Syn. *P. Carestiae*).—This also is useful for edging purposes. It bears pretty blue flowers in June, and averages 6 ins. high.

P. Michellii.—This is a pretty blue sort flowering in June, and growing 6 ins. high.

P. salignum.—Syn. *P. canescens* above.

P. serratum.—This is a blue summer flowering sort about 1 ft. high.

P. spicatum (Syn. *P. tetramericum*).—Paxton says this, known as SPIKED RAMPION, is occasionally eaten as an article of food. We have not tried it. It produces blue flowers from May onwards, and grows about 1½ ft. high.

P. urticifolium.—Syn. *P. Halleri* above.

Rock Garden Species.—Some of the smaller species are graceful rock-garden plants. Most of them are easy to grow in rocky soil and are propagated by seeds in the spring. We recommend the following :—

Phyteuma comosum.—This bears its leaves in a rosette. Flowers intense blue in heads. Site sunny limestone crevice. Flowering Period, July. Height, 3 ins.

P. orbiculare.—This is a tufted plant. Flowers deep blue in heads. Site open. Soil stony. Flowering Period, July to September. Height, 12 ins.

P. Scheuchzeri.—This is a biennial of light graceful habit. Flowers deep blue. Site open. Soil stony. Flowering Period, May to August. Height, 12 ins.

HORSE-BANE (*Œnanthe Phellandrium*).—See ŒNANTHE.

HORSE BEAN (*Vicia Faba equina*).—See *VICIA*.

HORSE-BRIER (*Smilax rotundifolia*). See *SMILAX*.

HORSE CHESTNUT.—A name applied to the genus *ÆSCULUS*, more especially to *Æ. Hippocastanum*. See *TREES*. See also under CHESTNUT in *NUT CULTURE*.

HORSE DROPPINGS. — See *HORSE MANURE*.

HORSE FENNEL.—See *SESELI*.

HORSE MANURE.

Horse manure is distinct from farmyard manure, though it is the prevailing constituent in the latter, and is more suitable for heavy soils than any other manure. There are many forms of it, upon some of the most important of which we enlarge below :—

Horse Droppings.—In large stables an effort is sometimes made to keep the droppings separate from the rest of the material, and this praiseworthy effort should be encouraged, since the droppings are the richest material of all. In their fresh state they are unsuitable save for making into liquid manure; it is after they have mellowed down in a heap for a month or so that they are so valuable for all the purposes to which horse manure is applied. Mixed with peat they form a valuable top-dressing, as is mentioned in our article on *TOP-DRESSING*, while with seaweed they form a very useful manure, as is mentioned in our article on *SEAWEED AS MANURE*. Stacked in a solid heap for twelve to eighteen months they mellow down into material almost as mild as leaf-mould or old hotbed manure. The horse droppings gathered from the roads, though useful for soils needing humus, are comparatively poor in plant food, however, and unless they can be well soaked with liquid manure and allowed to decompose for a few months are not of any great value. For use apply 3–4 cwt. per sq. rod.

Peat-Moss Litter.—On account of the great difficulty in getting straw for bedding horses on, peat-moss has been largely pressed into service, and when it becomes saturated with the urine of these animals it does not form a bad manure after it has rotted down. The droppings should be well mixed with the peat-moss for general purposes, otherwise some portions of the material will be comparatively poor while others will be very rich, and it is a good plan to arrange that the drain from the stalls in the stable shall deliver its contents on to the top of the heap of litter which has been cleared out, since otherwise material which is no longer fit for bedding purposes will be somewhat poor for the garden. Peat-moss manure may be used with success for general garden purposes, but is no good for the making of mushroom beds. For use apply 4–5 cwt. per sq. rod.

Sawdust Manure.—Horses are not infrequently bedded on sawdust, and the resulting manure is in consequence offered to gardeners. Its use is not to be commended, since the sawdust causes fungi of various kinds to come up. Where there is no other source of supply, instructions should be given to keep the droppings separate; these last can be used in the same manner as HORSE DROPPINGS (see above) so long as the soil has been previously well limed.

SHAVINGS MANURE, also, is detrimental. A few remarks on dealing with this are given under WOOD SHAVINGS MANURE below.

Strawy Manure.—This is what is usually known by the name of STABLE MANURE, and very good stuff it is when properly made,

though few gardeners or stablemen know how to do this. The animals are bedded on wheat straw, the driest of which is put back with fresh straw into the stalls each day, and that upon which the animals have watered is carted out. The ideal method of making this material into good stuff is to have a large pit dug, and into this the daily stable clearings are shot, the pit being situated so that the stable drain pours all its contents on to the top, including the water used when the stables are swilled out. Instead of tipping the stuff in and leaving it as loose as it can be to ferment and burn its own heart out, the material should be shot in and distributed in even layers, lightly sprayed with strong brine and then trodden as hard as possible. The pit should be large enough to hold at least a month's supply; then it can be emptied, the top portion being thrown into the bottom and the rest carted out into a field or into the manure yard, stacked again firmly, and if possible covered with soil to which a little gypsum has been added, until required for use. We need not enlarge here on all the purposes to which stable manure can be applied, except to point out that it is about the only material of which hotbeds and mushroom beds may be successfully made. (See articles on *Hotbeds* and *Mushrooms*.) About 3 cwt. of well-rotted stable dung is quite enough for each sq. rod of ground; but rather more is needed if dug in fairly fresh in the early winter.

Wood Shavings Manure.—In any districts where wood is much worked shavings or chips are cheap and available in ever-increasing quantities. These shavings are often offered very cheaply to horse owners for bedding, and the resulting manure is, in consequence, offered to gardeners. Such material should be avoided like poison, for it is possible to ruin a garden completely by its use, more so than is the case if Sawdust Manure, as mentioned above, is used. Endless fungi come up year after year, for the wood chips or shavings only rot away very slowly. Heavy dressings of lime will do much to kill the fungi, but it needs something stronger, such as gaslime, to kill them completely. No one can afford to be constantly dressing his land with gaslime, as it means that land so treated must lie vacant for three or four months each year and thus valuable winter crops are lost. It may happen, however, and indeed often does, that it is a matter of taking this wood shavings manure or going without. We all know that such things happen, though it must be admitted that it is rather a case of being between the devil and the deep sea. However, if such manure must be used, the effort referred to under Sawdust Manure above, should again be made in the case of the present material, and the droppings kept separate. The remaining material can be treated in one of two ways: it can either be charred by means of a slow smother fire, or it may be made into a stack, and every drop of available urine or slops poured over it for three or four months. This will then cause a large proportion of the wood to rot away, but the material will be charged with fungi spores, and the use of a powerful soil fungicide either before or with the manure is very necessary to prevent disaster. The droppings can be used at the same rate as horse droppings, of course; the other can be applied at the rate of about 3 cwt. per sq. rod.

Horses are sometimes bedded on other materials, such as fern litter,

damaged hay, leaves, road grass, etc., but these materials are not of sufficient importance to describe in detail.—E.

HORSE MINT or HORSEMINT.—See *MENTHA* and *MONARDA*.

HORSE MINT: AMERICAN. — See *MONARDA* and *POTHERBS*.

HORSE MUSHROOM.—See EDIBLE FUNGI in *FUNGI: EDIBLE AND HARMFUL*.

HORSE THISTLE.—See *CNICUS*.

HORSERADISH (*Cochlearia Armoracia*. Nat. Ord. Cruciferæ).—Although this plant grows most luxuriantly in soils of almost any description, it is only when a proper system of cultivation is followed that roots such as those offered for sale at first-class greengrocers need be expected. To obtain these as straight as a gun, varying in length from 1–2 ft., and about the thickness of a good walking-stick, the intending grower should not be against the trifling extra labour the preparation of a good bed involves.

Culture.—The position for the bed should be an open one, as far removed from the roots of trees as possible. Trench or double dig the ground very early in the winter, taking care to remove all stones, or other undecayable rubbish from the soil as the work proceeds.

Some time during February or March, purchase planting sets, about 9 ins. long, perfectly straight, having but a single eye, or, where what are termed "root-cuttings" are used, be sure these are planted top end uppermost, this being usually indicated by a level instead of a slanting cut. Always plant with a good wide dibber, making the hole perfectly straight and putting a little well-decayed manure at the bottom of each hole. Allow at least a foot between the rows, and from 9–12 ins. between each set. These may be covered with several inches of soil, or simply buried just below the surface.

Subsequent treatment consists of keeping the bed free from weeds, and at the end of November, taking up the whole crop, selecting the best roots for winter use, and others for making a new bed next season, care being taken to burn any bad-shaped or undersized roots. Cover those selected with dry earth for use as required.—F. R. C.

HOTBED FRAME.—This is referred to in the next article.

HOTBEDS.

Although not so popular now as they were before artificial heating by hot water pipes reached its present high state of perfection, few gardeners can altogether ignore the claims of the old-fashioned hotbed, and, where the necessary material can be cheaply had, one or more of these affords ready means of raising tender greenhouse or half-

hardy annuals which it would be unwise to sow in unheated greenhouses or frames until late in the season.

Where not wanted for these purposes, it is quite an easy matter to produce various out-of-season vegetables from fairly large beds made up in a sheltered corner outdoors.

Where immovable frames exist, a large hole excavated in the centre and filled with a few barrow-loads of the proper heating material affords just the bottom heat required for striking cuttings of various greenhouse or bedding plants, or giving a start to healthy cucumbers or melons for summer fruiting; frequent outside coverings of fresh material sufficing to maintain the interior of the frame at the required temperature.

For making these beds, some gardeners use nothing but manure fresh from the stables; others get satisfactory results from the use of a goodly proportion of this and fresh-gathered leaves, which for many weeks previous to use have been stored in a dry shed. Others having no manure, manage to get wonderful results from leaves alone, preference always being given to those from Beech, Oak, or Elm. It is necessary to add, however, that heat from such beds, although lasting, is slow to rise, and for this reason beds should be made up some time in advance of the date required for use.

Undoubtedly, beds made up of manure alone give the greatest heat, but unless they are of good size this heat declines so rapidly as to be positively dangerous to the occupants inside the frame. For this reason, in cold windy weather the outside should have the protection of sacks or mats, and outer linings of manure added very frequently.

Success with hotbeds depends very largely upon the proper preparation of whatever fermenting material is used, and a little extra attention is advisable.

When sufficient material has been got together to form the bed, mix this thoroughly, and make up in a conical heap. Turn it over every four or five days, and if the material is on the dry side apply a little water through a fine-rosed watering-can.

In turning the heap always endeavour to put the outside material into the middle of the heap as the work proceeds, thus making it all as uniform as possible.

After the third turning the permanent bed should be formed, and for this a good sunny position should be found, whenever possible protected from east or north winds.

Always make the bed of sufficient size to allow the frame to be placed in the centre, and leave a margin of at least 18 ins. on each side to allow the linings above mentioned being placed as required.

When completed place a good heap of soil in the centre, letting this be of a description most likely to suit whatever is to be grown upon the bed, thus ensuring it being of the proper temperature when the time arrives.—F. R. C.

[No seeds should be sown on the bed, or boxes of seeds put in the frame until the temperature of the bed has fallen to 65° F.—EDITOR.]

HOTEIA.—Now included in the genus *ASTILBE*.

HOULLETIA.—See *ORCHIDS*.

HOUMA (*Sophora tetraptera*).—See *SHRUBS* and *TREES*.

HOUND BERRY (*Solanum nigrum*).—See *SOLANUM*.

HOUND'S TONGUE. — See *CYNOGLOSSUM*.

HOUSELEEK.—A name applied to the genus *SEMPERVIVUM*, which see.

HOUSELEEK PENNYWORT (*Cotyledon chrysanthus*).—See *COTYLEDON*.

HOUSELEEK RUST. — See under SEMPERVIVUM in *DISEASES OF ROCK PLANTS*.

HOVER-FLIES. — See *INSECT FRIENDS*.

HOWEA.—For the best species see *PALMS*.

HUGUENINIA.—Now included in the genus *SISYMBRIUM*.

HUMATA.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING*.

HUMEA (Nat. Ord. Compositæ). This is a graceful and ornamental plant with fragrant foliage and drooping racemes of rosy-purple coloured flowers, and is useful for the conservatory or the flower garden in summer. It should be sown in slight heat in June, pricked out, then allowed to grow on, and shifted into larger pots as required. Good rich loam, leaf-mould, and sand is a suitable soil for the plant. Temperature required, 40–50° F.

Greenhouse Species.—*Humea elegans.*—Rosy red. Flowers in July. Height, 2–5 ft. Its variety *purpurea* is rosy-purple.

HUMMING-BIRD'S TRUMPET (*Zauschneria californica*). — See *ZAUSCHNERIA*.

HUMULUS (Nat. Ord. Urticaceæ). The best known species of this genus is *H. Lupulus*, the common HOP PLANT, famous in Kent and other counties, which is used when dried for brewing. As most people are aware, it is an easily grown perennial twining plant quite hardy in the south of England, but it requires something to scramble up or over (*i.e.* hop-poles) if it is to be successfully grown. Gardeners should note, however, that it is apt to spread at the roots, and becomes troublesome if planted among other shrubs. It may reach a height of 30 ft., when well suited, but the average height is 12–15 ft.

HUMUS.—See *MANURING: PRINCIPLES OF*, and *SOILS: THEIR ORIGIN AND NATURE*.

HUMUS FROM SEAWEED.—See *SEAWEED AS MANURE*.

HUNGARIAN OAK (*Quercus conferta*). See *TREES*.

HYACINTH (*Hyacinthus*. Nat. Ord. Liliaceæ). — **Culture.** — Hyacinths are no longer grown for the purposes of the show table, so there is no necessity for details of culture to be given for this purpose. Speaking in general terms, Hyacinths may be divided into (1) the early section made up of the Roman and so-called Italian varieties, and (2) the Dutch section. This last may again be sub-divided into (1) the large or ordinary varieties; (2) the small flowered or miniature varieties, which are really only immature bulbs three or four years old, instead of five or six years old; and (3) Prepared Hyacinths, which are bulbs treated by a special process which enables them to be forced into bloom much earlier than the non-treated bulbs. The following notes will be of interest:—

ROMAN HYACINTHS.—These should be potted in August, and if treated in the ordinary way of bulbs in pots they may then be had in flower before Christmas, and even at the end of November. Hyacinth bulbs resent being kept out of the ground less than most other kinds, and by successional potting of Romans, their season may be prolonged until the end of March or early April. It is, of course, essential to see that plenty of roots have been made before the plants are put into warmth.

Both Roman and the large spiked

varieties are particularly suitable for growing in undrained bowls or pans in fibre or sand. It does not appear to be generally known that sand or very light soil is equally as good as fibre for the rooting medium in drainless bowls. Experiments have proved that plants grown either in sand or soil flower a week or ten days earlier than those in fibre, if from the time of potting they have in every way been treated alike.

Dutch or large spiked Hyacinths like a light porous compost in pots. They call for no special cultural remarks, except that the top of the bulb when the operation of potting is finished should be on a level with the top of the soil. Some varieties begin life by showing a light green sugar-loaf sort of bud ; others from the first have the top of the young embryo flower-spike more or less exposed. It is well not to put these under fibre or sand, as they are very liable to injury. Great care, too, must be taken in watering them.

Hyacinths (not Romans) grown in pots in the usual way may be turned out in beds or borders as soon as the weather permits. After they have done flowering, and if left undisturbed, they will throw up useful little spikes for cutting another year.

Prepared or early forcing Hyacinths must be potted as soon as the bulbs can be obtained, that is in August or early September, and the usual routine followed. As soon as they have made good roots they must be placed in a moist heat of from 60–70° F., if bloom is wanted about Christmas. With less heat their flowering is delayed until the middle or end of January.

Varieties.—The varieties of ordinary miniature and prepared Hyacinths are practically the same, so only one list is given :—

Ordinary Hyacinths. — The following are a selection of single varieties :—

Dark Blue.—Grand Mâitre, Ivanhoe, King of the Blues, Marie, and Menelik.

Light Blue.—Czar Peter, Lord Derby, Perle Brilliant, Potgetier, and Schotel.

Maroon and Purple Shades.—Distinction (Claret), Lord Balfour (Rosy-mauve), and Prince of Wales (Violet, with white eye).

Pink and Rose-Pink.—Cavaignac, Charles Dickens, Jacques, Lady Derby, Maria Cornelia, and Ornament Rose.

Red Shades.—Garibaldi, General Pelissier, La Victoire, and Roi des Belges.

White Shades. — Corregio, La Franchise, La Grandesse, L'Innocence, and Madame Van der Hoop.

Yellow Shades.—City of Haarlem, King of the Yellows, and Oranje Boven (Rosy-orange).

Roman and Italian Hyacinths. Roman Hyacinths (*Hyacinthus orientalis albulus*) are always pure white, and flower much earlier than any other varieties. Italian Hyacinths (*Hyacinthus romanus*) somewhat resemble Roman Hyacinths, but do not flower quite so early. There are pink, white, and blue forms in commerce.

Double Hyacinths are now comparatively little grown in English gardens, so no list is given here.

J. J. & E. T. E.

HYACINTH : Historical Notes.

If the ordinary man in the street were asked to name a flower of Dutch origin and one indigenous to that country, it is more than probable that he would at once mention the Hyacinth. And yet, like another famous flower so largely and successfully cultivated in the Netherlands (we mean the

Tulip), this popular bulbous favourite is of Eastern origin.

There is a story that Hyacinthus, the son of a Spartan King, was beloved by Apollo and Zephyr, and as he preferred the Sun-god, Zephyr drove Apollo's quoit at his head and killed him. Apollo was so disconsolate at the death of Hyacinthus that he changed his blood into a flower which bore the dead boy's name.

Now it is only proper to observe that the name Hyacinth has, in times past, been attributed to other flowers than the one so generally known and grown in our gardens to-day. If we go back to our oldest authorities we find that *Hyacinthus orientalis*, the forerunner of the present garden Hyacinth, was introduced into Holland and grown with great success in the neighbourhood of Haarlem long before it was known to us here in England.

Among the numerous references to the flower by the older writers we may mention that it is figured and described by Clusius, Dodoens, Lobel, Matthiolus, and others, but the illustrations given by these ancient authors show that the type originally introduced has been wonderfully changed by the constant care bestowed upon it by the Dutch florists. Some of these men, like Voorhelm and Van Kampen of Haarlem, made remarkable progress in the transformation of theHyacinth from a poor weedy spike of flower to a fully clothed stem, strong, tall, erect, and well furnished with large double flowers closely arranged as we now know it, the spike forming a graceful pyramid in its many shades and colours.

We can follow the line of development and improvement very easily when we turn up the authorities. The earliest specimens figured bear only a faint resemblance to modern forms. Gerarde grew it in his garden in Holborn as early as 1596. Parkinson in his *Paradisus* deals very fully with the flower in 1629. At this period the examples begin to show some signs of amelioration, for in the Père d'Ardène's treatise on the Hyacinth there is an illustration giving great promise of advance.

With the opening of the eighteenth century, considerable movement appears to have taken place. The Père d'Ardène, a scholarly and experienced florist, wrote a series of little handbooks on the culture of flowers, one of them being devoted to the Hyacinth. Very shortly afterwards this was translated into Italian. Voorhelm, the Haarlem grower, also brought out a little work on the subject which likewise found an Italian translator, but the most important contribution to the literature of the subject in those days was St Simon's large quarto volume published in Amsterdam in 1768.

At that time Hyacinth culture was in full swing round about Haarlem, and St Simon's work, which is illustrated with ten full page plates, contains a catalogue of the Hyacinths known in the previous year. Thirteen pages, each in four columns, arranged in alphabetical order according to their colours, are given of the then known varieties, or, roughly speaking, a total of about 2500 varieties are mentioned.

The growing of the Hyacinth in our gardens, and particularly in glasses, did much to help on the work. Maddock of Walworth in his *Florist's Directory*, published in 1792, gives this flower the place of honour, as he does in his *Catalogue of Flowers*, etc., offered by him for sale. The flower had now been doubled, which form was the most

highly esteemed. A criterion of the properties of a fine double Hyacinth is given, and the form is illustrated on Plate No. 1. It is curious to note in Maddock's Catalogue not only the names but the prices of some of the best varieties of the day. Many were offered at only a few shillings a bulb, but others were very expensive. For instance, *Mirabeau*, a double blue, was priced at £3, 15s.; *Impératrice Romaine*, a double white, was £4, 15s.; a double red named *Comte de la Coste* was priced at £12, 12s.; another of the same type, *Louis XVI.*, was catalogued at £10, 10s. Collections, however, ranged from 100 bulbs all different, duly named, at £8, 8s., to the same number in colours, kept separate, but unnamed, at £1, 1s.

In a very rare old folio, which was never completed, entitled *The Florists' Delight*, which was started the year previous to the publication of Maddock's *Florist's Directory*, we find some beautifully executed plates of florists' flowers, natural size. There are two Hyacinths figured: one is called *Trianon*, a fine double blue, and the other *Flos Sanguineus*, a ruddy pink. In looking at these magnificent samples of English cultivation, well over a century ago, one can almost say that the maximum of perfection had then been arrived at.

The later history of the Hyacinth, unlike that of some flowers, is quite devoid of anything sensational. The late William Paul in a lecture on this flower in 1864 refers to the number of varieties grown in Haarlem in Philip Miller's day as about 2000, but tells us that in the previous year when he paid a visit to the most exclusive bulb garden in that city he found only 700 sorts, and probably not more than 200 of those were subjects of extensive commerce.—C. H. P.

HYBRIDISING AND CROSS-BREEDING.—Every one knows that garden plants, in general, are very different from the wild forms from which they must have originated. Vegetables, fruit, and flowers have been so modified by man that in many instances they bear but little resemblance to the plants from which they have been derived. For the purposes of this article we will not trouble ourselves as to the original species of plants from which garden varieties have been obtained, but confine our attention to a brief description of the methods which have been followed in the development of useful qualities in fruit and vegetables, and in the attainment of beauty in flowers. The full discussion of the subject is quite beyond the limits of the space at our disposal.

Among all the marvellous "new varieties" that are being produced year by year, it is almost needless to say that they are "varieties" pure and simple, and not new creations. We can bring about certain changes

in plants within certain limits, *but there are limits*. We can produce a plant intermediate between two existing ones, as, for example, in the case of the Loganberry, which is a "cross" between the Blackberry and Raspberry. But in the case of plants, which are altogether divergent in character, and which belong to different Natural Orders or Families, Nature calls a halt. It really comes to this: the power which brings about changes lies in Nature itself, and the directing of that power lies in man with the limitations of our present knowledge.

Selection.—Let us consider the simplest case first, that of changes brought about by Systematic Selection. Here it may at once be said that "Selection" has played a highly important part in the production of useful varieties quite apart from cross fertilisation and hybridisation.

It must have been noticed even by the veriest amateur that in the plants produced from a packet of seed, of either vegetables or flowers, there are frequently differences in the plants produced. These differences may be very marked, or so slight as to pass unnoticed. Even in seed that has been produced from one individual plant these differences arise: there is a tendency to vary or to "sport." The extent of this variation may be extremely small, but should this appeal to the mind of the keen observer as a change likely to enhance the usefulness of this particular class of plants, an immediate attempt to take advantage of it should, of course, be made. To do this the seed from the one or more plants that possesses the new characteristics is carefully saved and sown. Among the hundreds of plants thus raised there may be only a very few which come anything near the ideal; still there may be a few which are nearer to the features desired. Again, seed is saved to sow from these plants only. This time the result may give a higher percentage of the kind that is sought. More than that, the particular characteristic which was first noticed may be now more pronounced in one or more specimens. From these specimens seed is again saved and sown, and thus perhaps after many generations plants are obtained, which nearly all "come true" to the model set up; and what is more, these will have developed the characteristic first noticed far and beyond what was anticipated; and this characteristic can be maintained by careful selection year by year.

It must be clearly understood that in plant breeding the object should be the development of some *one* characteristic at a time. One does not attempt to change the habit of a plant in half a dozen directions at the same time, but it often happens that in breeding for some one desired end, other features are developed which may or may not be of use. In the former case selection for that particular feature is carried on.

For the purpose of making what has been said more clear, let us take a specific instance, namely, in Dwarf Beans. It is on record that some years ago a seedsman brought out a new form of bean pod which he thought would "go" with his customers. He gave it a name before it had been produced. He even published a description of it in his catalogue intimating that it would shortly be on sale. He told a celebrated bean breeder what he wanted, and it is an uncontested fact that in some two or three years a bean had been produced so nearly fulfilling his requirements that it

came on the market with the description given it before it was "made." How could such a thing be done? Without going into actual details, the course of procedure was that of going over thousands of plants, and selecting any that had the required characteristic in the slightest degree, selecting, and re-selecting from the progeny of these, and, in addition to this, "crossing" those having the most marked tendency in the required direction.

"Crossing" of plants will be dealt with in its proper place, but here we cannot lay too much stress upon the fact that great improvements in plants may be obtained simply by selecting those having favourable characteristics. Every gardener knows that a "rogue" in a row of plants is a departure from the type, which may be much below the standard of excellence; in that case it is pulled up and thrown away, and thus "rogueing" is a most important matter. On the other hand, "rogues" may at times have some useful characters, and thus may be used as a starting-point to produce in the next generation new desirable characters in a few of their progeny, and these characters may become more pronounced in future generations, and eventually be more or less "fixed." In dealing with this matter of "rogues," it can be easily understood that where plants are grown for seed, and where the object is to produce seed that will give plants true to type, every plant that differs from this type must be destroyed before it is allowed to flower.

Cross-breeding.—Now comes the question of cross-breeding. By this is meant the transference of the pollen of one flower to the proper organs in another flower of the same species. Both the terms "Hybridising" and "Cross-breeding" are somewhat loosely used, but for the purposes of this article we will take a "hybrid" to be the result of crossing one *species* with another species of the same genus, while cross-breeding is the result of crossing two *varieties* of the same species of the same genus.

Before it is possible to carry out this work the arrangement of male and female flowers must be understood. Some subjects have all the male flowers on one plant, and all the female flowers on another, as, for instance, the willow. Then there are subjects which have male flowers and female flowers borne on the same plant, to wit, the begonia and vegetable marrow. Lastly, we have plants whose flowers individually contain both the male and female elements; for example, the fuchsia, lily, the raspberry, and hosts of others. In fact, the larger majority of plants are included in this last class.

Now before a flower can produce seed it must be fertilised by some means or other, and to this end Nature has some marvellous arrangements. This part of the subject would fill a volume, but it must suffice to say that *on the whole* these arrangements are such as to prevent self-fertilisation—that is that the pollen of a flower does not come into contact with the portion of that same flower which is to bear the seed. Briefly, Nature discourages in-breeding. The other precaution which Nature appears to take is to preserve the fixity of species, but these statements must be regarded as true only within certain limits.

The objects of cross-breeding are to produce a plant more vigorous than either of its parents, and to transmit some special characteristics of those parents to the resulting cross. Scores of examples of flowers

and vegetables readily occur in our minds which have so changed during the past forty or fifty years that it is hard to believe that they have descended from such varieties as were known in those times. These have been the result of judicial cross-breeding. If, for instance, the tomato of to-day is compared with the tomato of years ago, an astonishing difference and improvement is noticeable. The same applies to beans, leeks, peas, etc.

In the floral world our great grandparents never dreamt of such things as our present-day cannas, fuchsias, geraniums, and hundreds of other marvels of the gardeners' art and genius.

How to Hybridise.—As to the methods followed in cross-breeding and hybridising any amount of printed directions are not of great value, but we will make clear the principles which govern the practice.

Let us suppose we have a fuchsia which has some peculiar beauty about it, but has a poor habit of growth. We would like to have a fuchsia possessing, more or less, this beauty, but of better habit, and perhaps better constitution. First of all then, another fuchsia whose flowers are fairly good and whose habit of growth is first class must be found, and, of course, both plants must be flowering at the same time. So many flowers of the first one just before they are about to open are selected; and in the same way so many of the other, and the heavy bursting buds of the first are carefully opened out. The pollen-bearing anthers which surround the central stigma are then removed, taking care that none of the finely divided pollen touches the stigma. With the aid of a camel's-hair brush, or fine steel scalpel, some of the pollen from the flowers on the second plant is transferred to the stigma on the plant we are dealing with, and this done, the flower is tied up in a fine paper bag so that bees and other insects cannot carry any other pollen to it. In many cases the pollen from the first plant may be used to fertilise flowers on the second, thus making a double cross in which the male element in one fertilises the other, and *vice versa*.

Sometimes hybridising and cross-breeding are done with a still more specific object in view, for instance, if a new pea is wanted which is both very hardy and very dwarf. In this case two parents have to be chosen each containing one of the specific characteristics it is desired the cross shall contain. All that there remains to be done is to cross and re-cross, the resulting product being selected and re-selected, and in a very few years the desired result will be obtained.

It may be pointed out in conclusion that in many cases plants closely allied as to species will not cross, and that many insuperable difficulties crop up. Those wishing to follow up this work would do well to seek information at the various Horticultural Departments of the University Colleges now fortunately so numerous. A practical demonstration will teach more than many weeks or months of reading.

HYDRAECIA. — See POTATO STEM MOTH in *INSECT PESTS*.

HYDRANGEA (Nat. Ord. Saxifragaceæ).—This is a genus of hardy and half-hardy flowering shrubs, averaging 2–10 ft. in height. They thrive in sandy soil and are best propagated by cuttings.

Culture. — Cuttings taken in August and potted at once into 3-inch pots in sandy soil will form flowering plants in a year's time.

Short, unflowered shoots should be chosen, and they must be kept close and shaded till rooted. The plants should be wintered in a frost-proof frame or cool greenhouse, and be potted on in the spring as required. To turn the flowers blue, water with a solution of sulphate of iron, putting ¼ oz. of the chemical into a gallon of water.

Uses.—For conservatory decoration, as specimen plants on terraces, lawns, etc., and for planting out in beds during summer, the plant has long been popular. The fact that its period of bloom (August and September) is rare among flowering shrubs, and the great length of time over which the flowers remain in condition, justifies the attention bestowed on it. In the south of England and other mild parts of the British Isles all the species are quite hardy, and *H. paniculata* is hardy in all parts of the country.

Varieties.—The following hybrids are derived from *H. hortensis*: Beauté Vendomoise, Générale Vicomtesse de Vibraye, Lilie Moullière, Mlle Rénée Gaillard, Mme Moullière, Radiant. They are all well worth growing, as also is *H. paniculata*.

HYDRAULIC CEMENT.—See *Mortar*.

HYDROCHLORIC ACID.—See *Acids: Their Uses in Horticulture*.

HYDROCOTYLE (Pennywort. Nat. Ord. Umbelliferæ).—This is a genus of hardy plants for the wetter portions of the wild garden. *H. vulgaris* is the best known species. It is the Common Pennywort, a wild plant of little value. As there are many better things we do not propose to describe any species here.

HYDROCYANIC ACID.—See *Acids: Their Uses in Horticulture*.

HYDROCYANIC ACID GAS.—See *Insect Pests: General Methods of Destruction*.

HYDROFLUORIC ACID and HYDROFLUOR-SILICIC ACID.—See *Acids: Their Uses in Horticulture*.

HYDROGEN SULPHATE OF SODA.—See Sodium Hydrogen Sulphate in *Soda and Sodium Compounds*.

HYDROPHYLLUM (Water-leaf. Nat. Ord. Hydrophyllaceæ).—This is a genus of dwarf plants suitable for the wetter portions of the wild garden or for the bog garden, growing as a rule about 6 ins. high. *H. virginicum*, popularly known as Shawanese Salad, is probably the best known species. Two others grown at Kew are *H. appendiculatum* and *H. canadense*. The first two of these species bear blue flowers, the last white, and all bloom from May to July.

HYDROXIDE OF CALCIUM and HYDROXIDE OF LIME.—See Calcium Hydroxide in *Lime Compounds*.

HYDROXIDE OF POTASH.—See Potassium Hydroxide in *Potash and Potassium Compounds*.

HYDROXIDE OF SODA.—See Sodium Hydroxide in *Soda and Sodium Compounds*.

HYGROMIA.—See under Slugs and Snails in *Insect Pests*.

HYLEMIA.—See Carnation Maggot in *Insect Pests*.

HYLOBIUS.—See Pine Weevil in *Insect Pests*.

HYLURGUS.—See Pine Beetle in *Insect Pests*.

HYMENANTHERA.—For the best species see *Shrubs*.

HYMENOCALLIS (Nat. Ord. Amaryllidaceæ).—This is a genus of hardy and half-hardy bulbs of easy culture, requiring no more than the usual treatment bestowed on such subjects. A rich light loam is the best, and propagation may either be effected by seeds or by little bulbs in the usual way.

They should be planted about three times deeper than the diameter of the bulbs and covered with litter in October.

What to Grow.—The following bear white flowers from May to August, and average 12–24 ins. in height. For detailed descriptions larger works must be consulted: *H. bistubata, H. calathina, H. grandiflora, H. glauca, H. lacera,*[1] *H. littoralis,*[1] and varieties; *H. Palmeri* and *H. tenuiflora. H. Amancaes*[1] is light golden-yellow. A number of stove species are purposely omitted.

HYMENOPHYLLUM.—For the best species see *FERNS AND FERN GARDENING.*

HYMONOMUTIDÆ. — See LITTLE ERMINE MOTHS in *INSECT PESTS.*

HYOSCYAMUS (HENBANE. Nat. Ord. Solanaceæ).—This is an unimportant genus of annuals and evergreens of no garden value and of weedy appearance. The best known species is *H. niger,* known as COMMON HENBANE, or merely as HENBANE, an intensely poisonous plant described under the latter name in our article on *MEDICINAL HERBS.*

HYOSERIS (Nat. Ord. Compositæ). This is an unimportant genus of hardy herbaceous plants of very easy culture, but of little value for the garden. The best known species is *H. foetida,* or SWINE'S SUCCORY, a plant sometimes given a place in the borders, but quite undeserving of such an attention.

HYPERICUM (ST JOHN'S WORT. Nat. Ord. Hypericaceæ).—This is a large genus of shrubby greenhouse evergreens, hardy deciduous shrubs, hardy annuals, hardy herbaceous perennials, and hardy evergreen rock plants. The first three sections are excluded as being beyond the scope of the present work. The hardy herbaceous perennials are of excessively easy culture, useful alike for shady portions of shrub borders, mixed borders, rock borders, and in the wild garden. They practically grow themselves when once planted in light, rich soil, to which a little peat and leaf-mould have been added. They are easy to propagate by division of the roots in March or by seeds in the early summer, while the best planting period is February and March. We recommend the following sorts from the large number which have been described, all of which are hardy:—

Hypericum crispum.—This is a yellow sort blooming in June and July, which grows about 12 ins. high.

H. decussatum.—Syn. *H. orientale ptarmicaefolium,* which see.

H. hirsutum.—This is a useful sort bearing yellow blooms from June to August, and growing 1 ft. high.

H. linarifolium.—This is a pretty yellow species blooming from midsummer to the end of August, and growing about 12 ins. high.

H. montanum.—This is another useful yellow-flowering species. It blooms from June to August, and grows about 1½ ft. high.

H. orientale.—This and its variety *ptarmicaefolium* (Syn. *H. decussatum*) are two very useful yellow-flowering species blooming from midsummer to the end of August, and averaging 1½ ft. in height.

H. perfoliatum.—This and its variety *latifolium* are a couple of dwarf-growing yellow sorts blooming in July, and rarely exceeding 12 ins. in height.

[1] These are the only hardy species, and even they cannot be regarded as hardy except in the warmest parts of the United Kingdom.—EDITOR.

H. pulchrum.—This is a pretty dwarf yellow sort blooming from June to August, and averaging 12 ins. in height.

H. tomentosum.—This is a late blooming dwarf yellow sort only coming into bloom in August and September, and averaging 9–12 ins. in height.

Rock Garden Species.—These are very pretty evergreens which will thrive very well if well-drained loamy soil is provided. They are best propagated by means of seeds sown in gentle heat in March. We recommend the following :—

Hypericum Coris.—This is a dwarf, tufted evergreen. Flowers rich yellow. Site sunny. Soil sandy loam. Flowering Period, May to September. Height, 3 ins.

H. nummularium.—This is a trailing species. Flowers bright yellow in racemes. Site sunny. Soil sandy loam. Flowering Period, June to September. Height, 3 ins.

H. olympicum.—This is a handsome greyish-leaved evergreen. Flowers large yellow. Site sunny. Soil light loam. Flowering Period, June to September. Height, 9 ins.

H. polyphyllum.—This is merely a small edition of above with yellow flowers. Height, 4 ins.

H. reptans.—This is a trailing plant with evergreen foliage. Flowers golden-yellow. Site bright sunny. Soil ordinary loam. Flowering Period, July to September. Height, 3 ins.

New Variety.

Hypericum læve-rubrum.—A new St John's Wort from Asia Minor, with orange-scarlet flowers, dark green leaves, and creeping stems. It is very suitable for rock garden culture.

See also *Shrubs.*

HYPOCHLORITE OF CALCIUM.—See Calcium Hypochlorite in *Lime Compounds.*

HYPCHOERIS (Nat. Ord. Compositæ).—This is a genus of plants popularly known by the name of Cat's Ear, and well known to pig breeders on account of being of food value to their stock. The plants are chiefly weedy hardy perennials of no garden value but of very easy culture. Four species are grown at Kew: of these *H. maculata* is sometimes found in large herbaceous borders when the collection is extensive, but otherwise the genus may be dispensed with. The species named bears yellow flowers from June to July, and grows about 12–18 ins. high.

HYSSOP (*Hyssopus officinalis*).—See *Hyssopus* and *Potherbs.*

HYSSOPUS (Nat. Ord. Labiatæ). This is an unimportant genus of hardy evergreen bitter herbs which are sometimes planted in the herbaceous border instead of being kept in the kitchen garden or herb border. The species most often grown is *H. officinalis*, known as Hyssop, a few remarks on the culture of which appear in our article on *Potherbs.*

INARCHING.—See GRAFTING in *PROPAGATION OF PLANTS.*

INCARVILLEA (Nat. Ord. Bignoniaceæ).—Although grown only to a limited extent, several species of this genus are well worth including in the herbaceous border as they are rather attractive hardy perennials, bearing Gloxinia-like flowers. They succeed in common, rich, light, well-drained soil in a sunny site, and may be propagated in the usual way by seeds sown in the spring and summer, or by division of the roots in the autumn or spring, at which times they may be successfully planted. A novel way of increasing one's stock is to slip off the young growths which form so freely just above the rootstock in the summer, and dibble these in as cuttings under a handlight in very sandy soil. The following is a selection of the best hardy sorts :—

Incarvillea brevipes.—This is a good sort with purple flowers blooming from June to September, and growing about 1 ft. high.

I. compacta.—This is a pretty purple sort blooming from June to September, and averaging 1–1½ ft. in height.

I. Delavayi.—This is the most popular and widely grown sort. Various forms of it bear rosy-carmine, deep purple, and lilac-purple flowers respectively. The blooming period extends from June to September, and the plants grow 1–2 ft. high.

I. grandiflora.—This sort frequently offered in nurserymen's lists may be synonymous with *I. Delavayi.* It bears deep rose-red flowers from June to September, and averages 12 ins. in height.

I. Olgae (Syn. *I. Koopmanni*).—This, though not very hardy, is a handsome sort, bearing large bright rose-pink flowers not unlike Pentstemons, from June to August, and growing 2½–4 ft. high.

I. variabilis.—This useful sort requires a warm spot. It bears attractive and somewhat vivid rosy-purple flowers in July and August, and grows 12–18 ins. high.

INCENSE CEDAR (*Juniperus thurifera*, the genus LIBOCEDRUS and *L. decurrens*).—See *TREES*.

INCENSE JUNIPER (*Juniperus thurifera*).—See *TREES*.

INCREASED PRODUCTION ON ALLOTMENTS.—The above subject has for many years been gradually asserting its importance, but the sudden emergency created by the Great War served to place it in the front rank. Some hints were undoubtedly gained from the booming of "French Gardening" a few years ago, but that system has made little headway in England on account of the outlay required. It was rather a fuller development of English Gardening that was called for, and this has in many cases been brought about.

Whilst allotments could be fairly looked upon as an old institution in many parts of the country, there was abundant evidence that a full use of them was not made. In proof of this, attention need only be called to the general bareness of many plots from September until spring. This state of affairs was slowly improved during the thirty years before 1914, but under recent conditions a more rapid improvement has been noticeable. Many new allotment holders, especially in our towns, have been quick to learn lessons bearing on increased production. This in turn has served to stimulate workers in the country, and there is a great future before all amateur food growers so long as work is not relaxed but further effort made. Plots can produce double or treble what they are doing, provided the right line is taken.

How to Obtain It.—What we have just said sounds quite impossible, but we shall now point out how to go to work.

In the first place, work has often been hindered by a water-logged soil. Under such conditions a full yield of produce is quite impossible. "Cold" and "late" are the expressive words applied to these plots. Deep digging is often of some assistance in view of this difficulty. Open trenches are also of great value, but in bad cases nothing but drain pipes will be satisfactory.

Next undoubtedly comes the value of good spade work, carried out in dry weather, and October being the commencement of the gardening year, digging started then serves to expose a larger surface to air and frost. This is invaluable, in view of seed-sowing in early spring. The depth of digging naturally depends partly on the worker's available time, but a double depth is to be strongly recommended, since no one can expect to increase his production unless he digs well and deeply.

The necessity of an occasional supply of lime must next be noted on account of the varied purposes it serves. On sour soil it has been known in the same season to treble the yield of crops, and on all soils, save those resting on chalk or limestone, it will help the crops greatly, and thus make them give greater return than they otherwise would.

If the greatest possible yield is to be obtained from the land, full use must be made both of artificial fertilisers and natural animal manures. Very often a timely application of the former will increase

the yield by one-third, and no one can expect reasonably good results unless he buries some dung in his land from year to year.

Other important ways of increasing production are found by the use of Catch Crops, Double Cropping, Rotational Cropping, and Successional Cropping. For particulars of these other articles must be consulted. Lastly, every gardener who desires to get more from his plot should study good gardening from the best authorities available, neglecting neither the scientific nor the practical aspect.—C. W.

INDIAN PINKS AND JAPAN PINKS (*Dianthus chinensis*. Nat. Ord. Caryophyllaceæ).—The genus Dianthus contains some two hundred species, more or less, of perennials or sub-shrubby plants, and a number of species are treated in the article on *DIANTHUS*. *D. chinensis* is best sown as an annual in heat, or in a cold frame during March, and planted out in May, when it will bloom from July till frost occurs. As a biennial it may be sown in June or July, and thinned to bloom the following year. The small flowered sort (*D. chinensis*) is known as the Chinese or Indian Pink, though it does not come from India; and the large flowered and fringed strains (*D. c. Heddewigii*) as the Japan Pink. The flowers are exceedingly variable in colour from white to carmine and crimson, often beautifully marked and laced, and single or double.

What to Grow.—*Dianthus chinensis* can be had in many colours both single and double. It flowers freely from July to October, and averages 9–12 ins. in height.

D. chinensis Heddewigii[1] can also be had in many brilliant colours both double and single. It blooms freely from July to October, and averages 6–15 ins. in height. Some of the best varieties of this include *Atkinsoni*, a single, blood-red garden hybrid blooming from July to August; *Brilliant Fringed*, a single-flowered strain with many intense colours, coming in from July to October; *Crimson Bells*, also single, and blood crimson, coming in about the same time; *Diadem*, a true double, many-coloured sort blooming from July to October; *Salmon Queen*, a single sort producing salmon-pink fringed flowers from July to October; *Scarlet Queen*, also single, but bearing vivid scarlet flowers from July to October; *Sutton's Superb*, a splendid single sort available in many colours, and blooming about the same time as the above; *The Bride*, a single white sort, the flowers of which are zoned crimson or purple, and which are

[1] Often offered by the trade as *Dianthus Heddewigii*.—EDITOR.

produced freely all the summer; *The Mikado*, a fine single or semi-double sort, producing finely fringed flowers from July to October; and *Vesuvius*, a further sort available in many glorious colours from scarlet to orange, the flowers of which are finely fringed, and produced freely all the summer and well into the autumn.—J. INSECT FRIENDS.

Insects as a group are looked upon by gardeners as enemies and pests, and many of the families most abundantly represented in gardens justify by their habits this bad opinion. Some of the common insects of the garden are, however, distinctly beneficial, and it is desirable that these should be recognised as friends so that, as far as possible, they may be accorded protection and encouragement. There can be no doubt that many members of the groups briefly described in this short article are of great service in destroying such injurious garden pests as caterpillars and green fly, to the extent of keeping their numbers from becoming permanently excessive. Predaceous insects cannot be expected, however, to exterminate the plant-eating creatures on which they feed; for any approach to extermination the gardener must make vigorous use of insecticides and soil fumigants.

Beetles.—The order of the *Coleoptera* or Beetles, which includes many destructive insects—chafers, weevils, and wireworms for example—comprises several families, most of whose members are undoubtedly allies of the gardener. Of these the more important are the ground-beetles and the ladybirds.

GROUND-BEETLES (*Carabidæ*).—These are beetles of active habit, with relatively long legs, that give them the power of running swiftly, and with the strong biting jaws or mandibles, sharp at the tip, enabling them to seize on the plant-eating insects which serve as their prey. In all beetles the fore-wings (elytra) are hard and firm, protecting the delicate, membranous hind-wings; in most of the ground-beetles these latter are reduced so as to be useless for flight, and the excessively strong fore-wings form a sort of armoured deck over the insect's hind-body. Thus beetles of this family present a very characteristic appearance as they run about in pursuit of creatures weaker than themselves. Some spend the day lurking under stones and go hunting by night, but others display their activities in the bright sunshine. The grubs or larvæ of ground-beetles have elongate, well-armoured bodies with three pairs of fairly long legs, each foot bearing two claws. They also get their living by chasing and

catching smaller insects. Many kinds of common ground-beetles live in gardens, so that they must devour a large number of plant-eating insects. It is well, however, to remember that the feeding habits of some members of this family are at times abnormal, and then they gnaw roots and stems instead of hunting for insect prey.

LADYBIRDS (*Coccinellidæ*). — The appearance of these stout, rotund little beetles with their conspicuous pattern of spots—red or yellow or black—is familiar to every gardener. They afford a great contrast to the ground-beetles, having short legs with only three segments on each foot, instead of the five usual in most beetles. These ladybirds are of the greatest service to the cultivator of the soil, as their food consists of "green fly" (aphis), scale-insects, and other destructive pests which suck sap from plants. The grubs of the ladybirds have the same feeding habits as the perfect insects; they have groups of strong spines on their somewhat elongate, tapering bodies, which are often marked with black and yellow spots, and six legs of moderate length. Being found in numbers on plants infected with "green fly," they are not infrequently mistakenly regarded by persons unfamiliar with their appearance as the cause of the damage. The more abundant the green fly, the greater, as a rule, will be the ladybird population on any plant, since a rich food supply is thus provided for the voracious ladybird grubs, which, under favourable conditions, develop so quickly that the whole series of transformations from egg to perfect beetle may be passed through in a month.

Hover-Flies (*Syrphi*). — Most members of the vast order of the *Diptera*, or Two-winged Flies, are looked upon as harmful insects, for many are blood-suckers and disease-carriers in the perfect winged state, or feed on plant tissue or as parasites in animals during the larval stage. One conspicuous and beautiful group of these insects is, however, distinctly beneficial, as the larvæ—like the ladybirds just described—feed on "green fly." These hover-flies are allies of the well-known house-fly and bluebottle family; they have shining and metallic bodies, often adorned with yellow bands so that they resemble small wasps. By the rapid beating of their delicate gauzy wings, they poise themselves in the air, where they may often be seen hovering over the flowering plants along a sunny garden border. In the perfect winged state they feed on the juices of flowers, and are of no great economic importance; from the eggs which they lay on plants are hatched the curious larvæ which must be reckoned among the most valuable of "garden friends." Hover-flies belong to the large assembly of the *Diptera* which have the degraded larval form known as the maggot—without legs, without a definite head, and usually tapering to the front end, where is situated the mouth armed with strong hooks for tearing up the food. The maggot is seen in its typical form in the soft, whitish offspring of a house-fly or bluebottle; in the young of a hover-fly we see a maggot with a comparatively firm body, protected by rows of strongish tubercles, able to move actively about on the leaves of the plant which it inhabits, impaling aphides on its mouth hooks, and sucking out their juices. In this way the hover-fly larva helps to keep the numbers of "green fly" within bounds, but just because they are most numerous on plants badly affected, and their mode of life is

not familiar to many gardeners, they are often mistakenly destroyed instead of being recognised as friends and preserved.

Ichneumon-Flies.—Several families of *Hymenoptera*, known generally as Ichneumon-flies, are perhaps the most important of all the gardener's insect friends. The Hymenoptera are characterised by two pairs of narrow membranous wings, jaws adapted both for biting and sucking, and an elaborately formed ovipositor, or egg-placer, in the female, modified into a sting in many families. The division of the order which includes the ichneumon-flies (as well as ants, bees, and wasps) is distinguished by a very slender waist in the middle of the body of the winged insect, and by the absence of legs in the grub or larva. Ichneumon-flies have the waist region of the body particularly long and narrow, and the female's ovipositor comes off beneath the abdomen, not at its extreme tip as appears to be the case in wasps and bees. The female ichneumon lays her eggs in the bodies of other insects—usually in the caterpillars of moths and butterflies—piercing the skin with her ovipositor; the legless grubs hatched from their eggs devour the caterpillars internally, so that they perish before completing their transformations. In this way the numbers of destructive, leaf-eating caterpillars are kept within bounds. Many ichneumons are of large size, and of these one or a few grubs only feed in a single caterpillar, but there are multitudes of tiny ichneumons of whose grubs a large number may inhabit one caterpillar of fair size. A well-known example of this latter arrangement is seen in the caterpillars of the White Cabbage Butterflies (among the most destructive of all garden insects), which are attacked by a small black ichneumon *Apanteles glomeratus*. The female of this fly lays thirty or more eggs in a single caterpillar; when the little ichneumon grubs have finished their destructive work they eat their way out and spin golden-coloured silk cocoons around the shrivelled body of their victim. The gardener who knows the history of these cocoons will, of course, be careful never to crush or injure them.

The victims of ichneumons are by no means restricted to caterpillars. Many kinds of aphides or "green fly" are attacked by small flies allied to *Apanteles*. An aphid that has been destroyed by one of their grubs shows a curious rotund, swollen aspect, a circular hole through which the parasite emerged being conspicuous in the brown hardened skin.

Lacewing-Flies.—These are insects of the order *Neuroptera*, with two pairs of ample membranous net-veined wings and biting jaws. Their active grubs live on plants infected with aphides, among which they wander, and on which they prey. The lacewing grub has long slender mandibles, on which the aphid is impaled and its juices sucked out. Some of the "aphid lions"—as these lacewing grubs are sometimes called—attach the shrivelled skins of their victims to the tubercles that cover their bodies, so that they wander around like the primitive human hunter attired in the spoils of the creatures that they have slain and devoured.

G. H. C.

INSECT PESTS.

[The following article gives a brief description and means of treatment for all the more common and important garden pests, and the gardener is not often likely to meet with those which are excluded.—ED.]

American Blight. See WOOLLY APHIS.

Ants (*Formicidæ*).—Ants, of which there are many kinds, are very harmful. They cause annoyance by making hills in field and gardens; they damage seedlings, etc., by their workings in the soil, and carry Aphides from place to place, thus starting new centres of attack. They may also damage soft fruit and certain plants by devouring them. Soil may become so infected that it is almost valueless; on the other hand, Ants may reclaim barren land, such as shingle, by their bringing small material to the surface, and so commence the formation of soil.

TREATMENT.—Trace out the nests, and either dig in naphthalene, or pour in boiling soap and water. Tanglefoot bands will prevent them carrying Aphides from one tree to another. White arsenic mixed with honey and put in saucers near their runs will drive them away, or the ground may be watered with a solution of 4 oz. carbolic acid per 20 gallons of water.

Aphis. See APPLE APHIDES and ROSE APHIDES.

Apple Aphides (*Aphis malifoliae*, etc.).—Apple foliage is often badly curled and scorched by this purple and pink Aphis, which is covered with meal. Two green kinds also occur, namely, *Aphis pomi* and *Siphocoryne avenae*. They all winter on the apple in the egg stage. *A. malifoliae* flies in summer to plantains, etc., *S. avenae* to oats. *Aphis pomi* occurs all the year on the apple and pear trees.

TREATMENT.—For the leaf curler spray with lime and salt just as the buds are commencing to burst. For the others spray with nicotine and soap when seen on the leaves or blossom.

Apple Blossom Weevil (*Anthonomus pomorum*).—This is a reddish-grey weevil, about a quarter of an inch long, with a V-shaped pale mark on the back, and with a long curved snout and elbowed feelers. It hibernates under the bark of trees and in the soil from which it comes out in spring, when it lays its eggs in the blossom buds before they open out. Attacked blossoms never develop, but the petals remain closed and turn brown. This is what is known as "capped blossom." The white maggot changes to a yellow pupa in the dead blossom, and the weevil eats its way out when hatched.

PREVENTION.—Keep the trees clean. Jar off the weevils when they are placing their eggs on to tarred sheets and spray with lime salt wash. Keep poultry on infested land.

Apple Sawfly (*Hoplocampa testudinea*).—The maggot of this Sawfly may easily be mistaken for that of the CODLING MOTH (which see) as it lives inside the young apples and quickly ruins them. It can, however, be at once distinguished from the latter by the greater number of pro-legs, their more curved position, and feebler movements. It works also in a somewhat different manner. The adult or Sawfly, which is somewhat similar to the CURRANT AND GOOSEBERRY SAWFLIES (which see), lays her eggs in the opened blossoms, and the maggots hatching from them mature in the young fruitlets. More than one fruitlet may be spoiled by a single larva. On reaching maturity the maggots fall to the ground and remain as such in the soil until the spring, when they pupate. There is normally only one brood a year.

PREVENTION.—Pick off and destroy all attacked fruitlets showing holes in them, and well cultivate the land under the trees.

Apple Sucker (*Psylla mali*).—A small green insect with four transparent wings about the size of an Aphis, from whch it can be distinguished by its skipping movements.

Eggs are laid in the autumn near the buds of apple trees, and are just visible to the naked eye. These hatch at the time of the bursting of the buds, and the young enter them and feed by suction. The insects are flattish, at first rather dark, but become green: from their bodies they exude fine pale threads and little mealy globules. Blossom trusses are speedily ruined by them. Later, nymphs are formed with wing buds and more of the woolly excrement. They become winged in June.

PREVENTION AND TREATMENT.—Spray the trees in February with lime and salt wash. During an attack spray with nicotine and soap.

Asparagus Beetle (*Crioceris asparagi*).—This is a beetle a quarter of an inch long, which is of dark bluish-green colour. It has a rusty red thorax with yellow patches on the wing-cases, and red edges to them. It hibernates under rubbish during the winter, coming out in the spring to lay its dark brown eggs on the shoots. In four to ten days larvæ hatch out; they are a dirty olive-green colour, and have six black legs. They have a pair of foot-like tubercles on each segment, and an anal pair by which they hold on to the plant. In a fortnight the larvæ are mature, and fall to the ground to pupate, the yellow pupæ giving rise to the beetles in a fortnight or three weeks. The later broods lay their eggs on the fronds, at right angles to the surface, and the larvæ strip the feathery growth.

PREVENTION AND TREATMENT.—Turn ducks on beds attacked. Spray the fronds with arsenate of lead to kill the larvæ.

Asparagus Fly (*Platyparea poecilloptera*).—This is a small fly of brown colour with four light bars on the body and the wings. It has brown markings much like the CELERY FLY (which see), and is about the same size. It occurs locally from April to June, and lays eggs beneath the scales of the asparagus heads. The larvæ bore into the young shoots and stalks of the fronds, and eat downwards. They all pupate in winter, and hibernate in the underground portions of the stems.

TREATMENT.—It is said that if rods dipped in any sweet sticky substance are put in the soil the flies alight and are caught, but in any case all injured shoots should be destroyed.

Bean Aphis (*Aphis rumicis*).—This Aphis, which is often called BLACK ARMY, BLACK FLY, or COLLIER, frequently causes much loss in beans, and may attack peas, as well as many other plants, such as docks, dahlias, poppies, and the spindle tree (*Euonymus*). It winters on the spindle (*Euonymus sp.*), and also lives on docks (*Rumex*) in the egg stage. The eggs hatch in the spring, and the insects eventually become winged, some flying to poppies, others to docks, and last of all to beans, where they settle on the tops of the plants, soon commencing to produce wingless living young. These soon do the same, until the tops of the plants get covered with a black, sticky mass which spreads down to the pods. As the beans ripen off the aphides fly to docks, poppies, thistles, etc., and later back again to the spindle tree.

PREVENTION AND TREATMENT.—Destroy as far as possible all docks and poppies and spindle trees. Pinch the tops out of broad beans and burn them, to prevent the attack starting, remembering that the young can only live in the young tender top growths. When present dust with Belumnite, or spray with soft soap and quassia, having pre-

viously picked off the worst infected heads.

Beet Carrion Beetles (*Silphidæ*).—Two blackish beetles known as *Silpha opaca* and *S. atrata* destroy mangolds and sugar beets abroad, but in this country they are of little importance. The beetles are about half an inch long; they are flattish, and when fresh are covered with reddish-brown down. This, however, is soon rubbed off and the body appears black. In *S. opaca* the elytra have each three ridges, and between the second and third ridge is a black spot, and the tip of the body is tawny. *S. atrata* is black and shiny. The beetles hibernate, and are normally carrion feeders; they now and then attack mangolds and beets in the larval stage. The larvæ are dark, flattish, and broad, similar to Woodlice in form—but flat, with the sides of the body notched, about two-fifths of an inch long. They have six legs in front and two anal spines. They occur also in farmyard manure.

Treatment.—Where these insects are abundant, they can be caught by placing a newly flayed sheep-skin on the ground. The insects will collect under this and the skin can be put into boiling water to kill the creatures.

Beet Fly (*Pegomyia betæ*).—Beetroots and mangolds are often attacked by the larvæ of this fly, which is very like the Onion Fly, which see. The maggots burrow into the leaves and blister them, doing endless harm. The fly appears from late March to June, and sometimes on into late July. The female lays small snowy-white eggs which are placed two to six, side by side under the leaves, but usually in groups of four. The eggs hatch in from five to ten days and the footless maggots at once enter the leaves. When mature the larvæ are about one-third of an inch in length, and then fall to the ground to pupate. Another brood of flies will appear, and possibly a third, until the autumn when they pupate for winter in the soil.

Prevention and Treatment.—Crush all blisters seen early in the season, and deeply trench all infected soil. Give rich and stimulating manures to beet growing on infected ground. In gardens and allotments the attacked plants may be sprayed with nicotine wash to kill the maggots. Where an attack is always expected sow the seed several weeks later than usual.

Big Bud (*Eriophyes ribis*).—This disease, common in black currants, is caused by a minute elongated mite only just visible with a pocket lens. Numbers get into a bud and reproduce, causing it to swell up very abnormally. As the buds die the mites migrate to others, and are carried from bush to bush and garden to garden by the wind, birds, winged insects, or even by the gardener's clothes, and by means of baskets into which fruit is picked. The mites can be found all the year round; breedings and migration, however, take place mainly in the autumn and spring, though eggs may also be found throughout the winter. Normal buds may contain a few mites and so escape detection. Red currants may also be affected. Some varieties such as *Baldwins* and *Black Naples* are more affected than others, such as *Boskoops Giant*, and the French; none, however, are immune.

Prevention and Treatment.—Hand pick and burn all swollen buds. If only a few occur pick off the bud above and the one below the swollen one. If a bush is badly attacked and ceases to bear a paying crop, grub up and burn it. Treat soil where bushes have been taken up with naphthalene or any strong soil

fumigant, but replant if possible in fresh ground. Never plant cuttings unless they have been soaked in water for a couple of days before planting. Spraying, unless done a great number of times, does not succeed, and more will be spent than gained.

Brown Scales (*Lecanium*).—Soft brown fat scales or *Coccidæ*, belonging to the genus *Lecanium*, often do much harm to currants, gooseberries, peaches, plums, and plants in general under glass. The GOOSEBERRY SCALE (*L. persicae ribis*) and the PEACH SCALE (*L. persicae*) are very alike. The dead adult skin with ova beneath is oval, brown, convex, and notched behind, and about a quarter of an inch in length. Eggs occur beneath this, as a fine yellowish dust; they hatch in autumn into small oval, flattish, and pale reddish or slaty larvæ, commencing to grow in the spring into the mature scale insect. They attack both the wood and the leaves.

TREATMENT.—Spray in the winter with lime sulphur wash.

Brown Tail Moth (*Euproctis chrysorrhoea*).—This is a snow-white moth with a faint black spot on the front wings. The apex of its body has a rich deep golden-brown tuft of hairs and is very thick in the female; the wing expanse being one and a quarter to one and three-quarter inches. It occurs in August and September, and lays eggs in masses on the leaves covered with hairs from the tail. The caterpillars hibernate in colonies in small winter silken nests. In the spring they form colonies which live in larger silken nests. When mature they are deep brown with red-brown hairs; they have white spots on each side, a narrow broken double red line down the back, and two red tubercles on the eleventh and twelfth segments. They spin up cocoons amongst the foliage, and pupate late in June and July. The larval hairs are barbed and produce a rash. It attacks fruit, roses, hawthorn, sea-buckthorn, and some forest trees.

TREATMENT.—Cut off all winter tents and burn. Spray in summer with arsenate of lead. The presence of this insect must be notified to the Board of Agriculture, Whitehall, London, S.W. 1, unless the gardener desires to be fined £10.

Bulb Mite (*Rhizoglyphus echinopus*).—This is a very common small milky-white or yellowish-white mite, tinged with rusty red; it has four pairs of red legs and a red rostrum, the first two pairs of legs being the longest, and is only just visible to the naked eye. It feeds on bulbs of hyacinths, narcissi, tulips, onions, eucharis, and other lilies; also the tubers of dahlias and potatoes. It may do much damage to bulbs, in checking growth, when the leaves turn yellow, and no flowers result, or, worse still, the bulbs may rot from its attack. The young have six legs and are hatched on and in the bulbs.

TREATMENT.—Soak all bulbs likely to be affected in water at 125° F., for a few minutes, first dissolving some soft soap in the water. Another useful method is to wash the bulb in potassium sulphide, putting about 1 oz. of the chemical into a gallon of water.

Cabbage Leaf and Stalk Miner (*Phytomyza flavicornis*).—Cabbage and other Brassicæ may have the petroles and leaf stalks mined by footless larvæ; these are of a small fly called *Phytomyza flavicornis*, which is about a tenth of an inch long. When mature the maggots eat their way out of the leaf-stalks, etc., and pupate as small brown pupæ in the soil. The fly is dusky black. Attacked leaves turn pre-

maturely yellow and die, and the premature bursting of the heads of spring cabbage is attributed in some cases to this insect. No treatment is known.

Cabbage Moth (*Mamestra brassicæ*).—This is a moth with wing expanse of one and three-quarter inches, which is of a dark grey-brown colour and varied with dark and lighter marks on the front wings. It occurs from May into late June. The caterpillars attack many plants outside the cabbage tribe, especially tomatoes under glass; they foul the plants as well as doing damage by actually eating them. They vary in colour but are usually brown, smoky brown, or greenish-brown, and are paler beneath. When full grown they are one and a quarter inches long; and if disturbed roll themselves up. They change to a shiny brown naked pupa in the soil.

TREATMENT.—Spray attacked cabbage plants with 2 oz. of salt to a gallon of water, or dust with Belumnite. Trap the moths in glass-houses with sweetened fluids in jars, and spray young tomatoes with arsenate of lead.

Cabbage Root Fly (*Phorbia brassicæ*).—All kinds of Brassicæ, especially cabbages and cauliflowers, are often ruined by the maggots of this fly, which resembles the House Fly. These maggots tunnel into the stems, checking the growth considerably, and large plants may be so weakened that the wind blows them over. When badly attacked, the plants wilt, and look sickly or fall over. The grubs are footless, and very like those of the ONION FLY, which see. They turn to brown pupæ in the soil and in the stalks. Several broods occur during the year.

PREVENTION AND TREATMENT.—Either dibble in the young plants with soot and old lime or ashes, or protect them with felt discs that can be obtained from any horticultural sundriesmen. The soil should be firm and level so that the tarred discs can be put down flat. Watering with a solution of hellebore (1 oz. of hellebore per gallon of water) is another way of combating this pest.

Cabbage White Butterflies (*Pieridæ*).—There are three species of these which attack all Brassicæ, the LARGE WHITE BUTTERFLY (*P. brassicæ*), the SMALL WHITE BUTTERFLY (*P. rapæ*), and the GREEN VEINED WHITE BUTTERFLY (*P. napi*). Most damage is done by the first named, whose wing expanse is often two and three-quarter inches. The female lays her yellow eggs in clusters on the leaves. The caterpillars, which are too well known to need description, are more or less gregarious, and eat the leaves often to mere skeletons. They mature in a month and then become chrysalids, these being often seen on the walls of outhouses, palings, trees, etc.

PREVENTION AND TREATMENT.—Collect all egg masses and young broods of larvæ. Destroy all wintering chrysalids. Spray or water attacked plants with weak salt and water, or dust with Belumnite.

Cabbage White Fly (*Aleyrodes proletella*).—Several species of so-called "White Flies" or "Snow Flies" exist—one is found harmful to Brassicæ, another (*A. vapariorum*) is under glass to Tomatoes especially. These small mealy snow-white insects are related to Scale Insects and Aphides. They live by suction; both the body and wings are covered with a fine white meal. They place their eggs singly on or under the leaves, sometimes covering them with white powder. The eggs, which hatch in a few days, give rise to larvæ covered by a trans-

parent scale of small size. Later they become an opaque white with two yellow spots, and in eight to twenty days turn to pupæ under the "scale," hatching out four to ten days later. Many broods occur in the year. They produce brown and yellow patches on the leaves. The one in cucumber and tomato houses works similarly to the Cabbage species.

PREVENTION AND TREATMENT.—Destroy all outside leaves and stalks of Brassicæ. If the attack is severe spray with soft soap solution, putting ½ lb. into 5 gallons of water. Attacks under glass may be controlled by fumigating with tobacco preparations, two or three times at intervals of a fortnight, or with hydrocyanic acid gas.

Carnation Maggot (*Hylemyia nigrescens*).—This is very similar to the BEET FLY, which see. It lays its eggs on carnations, and the footless maggots coming from them eat into the leaf, and down to the centre of the shoot, where they tunnel into the pith and so kill the plant. At first they burrow into the leaves, making pale lines or more or less sinuous tunnels. They pupate in the plants, and also the soil. Young plants, especially layers, suffer most.

TREATMENT.—There is no means of prevention, but all attacked plants should be pulled up and burnt. If a shoot is flagging pull out the point, and if maggots occur they can be seen by cutting a slit down the shoot.

Carnivorous Slugs (*Testacellæ*).—Certain fat yellowish slugs may be found in the soil which have a small *external* shell, and are often regarded as pests. As these feed upon other slugs and insects, however, as well as earthworms, they should be protected.

Carrot Fly (*Psila rosæ*).—The maggots of this fly cause the "rust" in carrots, which is a common disease. The fly is less than half an inch across the expanded wings; it is shiny, and of a metallic blackish-green colour, with a large yellow head, black eyes, and yellow legs. It appears when the carrots are young, and lays its eggs on them, penetrating into the soil. Grubs may be found in the roots between the end of May and on to the time the carrots are lifted, several broods occurring each season. When mature the maggots change to sausage-shaped brown pupæ in the carrots or soil. The late broods all pupate in the soil of the carrot beds. Some few, however, may be lifted with the carrots and pupate in the store house.

PREVENTION AND TREATMENT.—Double dig or trench the infected land after an attack. Spread a mixture of ash or sand and paraffin oil (1 pint of oil to a bushel) over the young plants after thinning, and later apply soot freely. Burn all diseased carrots at once; to leave them rotting on the ground is a certain means of encouraging the pest.

Cattleya Fly (*Isosoma orchidearum*).—This is a small Hymenopterous insect belonging to the *Chalcididæ*, most of which are parasites of other insects. The fly is a fifth of an inch long; it is black, and has four transparent wings. Its larvæ attack the pseudo-bulbs and the other parts of Orchids, causing the invaded areas to swell up and turn black. They are white and footless, pupating in the galls, after which the small flies eat their way out, leaving tiny round holes. Small orange footless maggots also attack the plants; these are the larvæ of a small fly called *Cecidomyia cattleyæ*.

TREATMENT.—All galled growth should be carefully cut away, or the galls cut open and the maggots

destroyed. Badly attacked houses should be frequently fumigated with tobacco.

Celery Fly (*Acidia heraclei*).—Celery and celeriac are often quite spoilt by the numerous blisters produced in the leaves by this small fly's maggot, and in some years parsnips are attacked in the same way. When this occurs amateurs often imagine the damage is due to a distinct fly, but the so-called PARSNIP FLY is really the one under notice. The fly is nearly half an inch in wing expanse; it has mottled wings and bright green eyes. The female lays her eggs on the leaf, and the young maggots burrow into the tissue, where they cause the well-known blister-like scars. When mature they turn to yellow pupæ in the leaves and a few in the soil. The fly lays its eggs in the young plants, especially before being set out from April to June. Several generations occur, maggots being found in the leaves as late as December.

PREVENTION AND TREATMENT.—See that the seedlings are protected by muslin screens on bright days so as to prevent them being attacked. Never plant out any showing even small blisters. Crush all the first blisters that occur, and so prevent subsequent broods. Dry spray the rows in June with Belumnite, or spray with nicotine and soap (¾ oz. nicotine, 2 oz. soap, and 10 gallons of water), as soon as the blisters are noticed. Deeply trench all land where celery has been grown, and keep the rows freely fed and watered in dry weather.

Celery Stem Fly (*Piophila apii*)—This fly has been little known since 1848, and is not important. So little is known about it that no treatment can be advised, beyond that of keeping the plants healthy by frequent watering and feeding.

Centipedes. — Although many people regard these as harmful pests, since they are related to the MILLEPEDES (which see), they are beneficial and should not be destroyed. They can be distinguished from the latter as they have only one pair of legs on each segment. There are several kinds, one of the commonest being *Geophilus longicornis*. Their antennæ are long, and this also enables us to distinguish them from the Millepedes, many of which are exceedingly harmful.

Chafers (*Melolonthidæ*). — These are large, fat, dirty, white grubs, swollen at their ends, often found attacking garden plants, vine roots, etc. Chafer grubs have a large head, six jointed legs in front, and are very sluggish; they feed upon the roots of all manner of plants and even trees. The two most abundant are the JUNE BUG or SMALL COCKCHAFER (*Rhizotrogus solstitialis*), and the MAY BUG or LARGE COCKCHAFER (*Melolontha vulgaris*) The first is about two-thirds of an inch long and is pale brownish. It has four raised ribs on each wing case. The latter is an inch long, and has a black thorax, reddish-brown wing-cases, with four raised lines on each side, and at the sides of the body five white spots separated by black; the abdomen in both passes beyond the wing-cases, and in the female ends in a downwardly bent horny egg-tube. The LARGE CHAFER GRUB is one and a half inches long: it takes three to four years to mature, but the JUNE BUG MAGGOT lives only one year in the soil. The beetles collect in numbers on isolated trees, around which they may be seen flying in masses in the evening.

PREVENTION AND TREATMENT.—The grubs may be destroyed by digging in naphthalene or patent soil fumigants, the former at the rate of 2 cwt. to the acre. Many may

be trapped in vine borders, etc., by placing a turf upside down in the soil, and examining this at frequent intervals. The beetles may also be jarred off the trees in day-time and crushed or given to pigs.

Click Beetles. See under WIREWORMS.

Cockchafer Grubs. See CHAFERS.

Codling Moth (*Carpocapsa pomonella*).—This is a small moth three-quarters of an inch long, with dark grey and grey fore-wings, on which are darker wavy lines and a metallic patch at each corner, the hind-wings being a dark slaty-grey. It occurs in the orchard and garden at dusk, about or soon after the falling of the apple and pear blossom. It lays its minute flat eggs on the young apples or pears, and the maggots or larvæ coming from them enter the fruitlets by the "eye" and tunnel into them, and eventually escape by another opening at the sides, top, or base. The maggots are a dirty white to a dull pinkish colour, and are about half an inch long. They have six true legs, four pairs of sucker feet, and anal pro-legs. They fall with or from the apples, and crawl back up the trees to pupate under the bark, moss, lichen, and bands. They remain as larvæ as a rule till the spring and then pupate, but now and then do so at once, and a second brood then attacks the late apples.

PREVENTION AND TREATMENT.—Band standard and half-standard trees with sacking in spring and leave this on till the autumn or winter. Then the ascending larvæ will pupate beneath and can at leisure be killed. Spray cordons and bush trees with arsenate of lead within ten days of the falling of the blossom. Employ poultry in the attacked orchard, and turn pigs in when the fruit is falling.

Colorado Beetle (*Doryphora decemlineata*).—This is an American beetle which is very harmful to potatoes. It has occurred once in this country, and its presence must be notified to the Board of Agriculture and Fisheries at Whitehall. The beetle is a little less than half an inch long; its colour is yellow, and it has five long dark lines on each wing-case, and dark marks on the thorax, the wings themselves being a marked rosy hue. It hibernates under the soil and under rubbish, from a few inches to 2 ft. in depth, and lays yellow oval eggs on the potato and other plants, the larvæ feeding on the foliage. The young are dull reddish-brown, and bear some resemblance to Ladybird larvæ; later they vary from orange to brick-red marked with rows of black spots. They pupate in the soil.

PREVENTION AND TREATMENT.—This insect is dealt with officially by the Board of Agriculture. In America affected plants are sprayed with Paris green or arsenate of lead.

Crucifer Midge (*Cecidomyia brassicæ*).—This is a small two-winged "gall-fly," with black head and thorax. It has a pinkish abdomen banded with dark brown, and black legs silvery beneath. It lays its eggs in young cruciferous seedpods in which small white footless maggots are found in May and June. These fall to the ground to pupate from the split pods, and a second brood of flies occurs a few days later.

TREATMENT.—Where the seed heads are badly attacked it is best to give seed production up and burn the lot; there is no remedy, but the central shoot may be pinched off so that others grow: these will be free from maggots.

Cuckoo Spit (*Philaenus spumaria*).—The Cuckoo Spit on roses, other plants, and even on apple trees, is too well known to need description. It is caused by an insect known as the FROG HOPPER, which is related

to the CAPSID BUGS—creatures which live by sucking out the sap of plants. It lays its eggs in the plant, and the young wingless larvæ feed by sucking the sap and cover themselves with a frothy mass, under which they change to nymphæ, and from this stage in the early autumn the winged and jumping Frog Hoppers appear. Rambler roses are particularly liable to attack, and so are chrysanthemums. The pests stunt all growth above them.

TREATMENT.—Spray forcefully with nicotine and soap, or pyridine and soap solution.

Currant and Gooseberry Sawflies (*Nematus ribesii*).—Both currants and gooseberries are often defoliated by so-called FALSE CATERPILLARS, which are the larvæ of a Sawfly. These larvæ range in colour from bluish-green to green; they are spotted with black, marked with yellow and blue at the sides, the first and last but one segment of the body being yellow. When full grown they reach half an inch in length, and then become pale green, except for the yellow behind the head and on the tail. The adult Sawfly is about half an inch in wing expanse, and has four transparent wings. The female has an orange body, the male a dark one; and the thorax of both is black and yellow. The Sawflies appear in April, and the females lay their eggs along the veins under the leaves. The eggs hatch in five to seven days, and the young larvæ feed together, eating out the well-known small round holes in the leaves. Later they pass out over the foliage, and often completely destroy it. In four or five weeks the larvæ reach three-quarters of an inch in length and fall to the ground to pupate in earthen cocoons, the pupæ hatching out in two to three weeks. The winter is passed in the soil under the bushes. The Sawfly larvæ have all more than four pairs of pro-legs, and so can at once be distinguished from the larvæ of any butterfly or moth, which never have more than four pairs of pro-legs.

PREVENTION AND TREATMENT.—Pick off all early attacked leaves, showing the small round holes. Spray with arsenate of lead or blow Belumnite or hellebore over the attacked bushes. If the fruit is to be picked and used green, apply 1 lb. of soft soap to 10 gallons of water as a heavy wash.

Currant Clearwing (*Aegeria tipuliformis*).—This is a small "clearwing" moth, two-thirds of an inch in wing expanse, the body and thorax of which are purplish-black with yellow bands. It has an expanded tail, and the clear wings have black fringes as well as black veins, also a yellow sheen. It occurs in late May and June, laying its eggs on currants, especially of black variety, and the larvæ tunnel into the shoots, working up and down the stems during the winter. In April they are pale caterpillars less than an inch long, which then pupate in the black tunnel in the shoot or stem.

TREATMENT.—Prune back all stems that are dying until the black tunnel is cut away, and burn with the caterpillars in them.

Diamond Back Moth (*Plutella maculipennis*).—This is a small moth like a Clothes Moth, but the wings are folded roof-shape on the body. The front wings are reddish-brown to slaty-brown, with a pale yellowish white border, and when folded the pale edges meet, and form diamond-shaped areas. The hind wings are slaty-grey with long fringes. It occurs in June and July, laying its eggs under the leaves, the larvæ feeding on cabbage, turnips, and

all Cruciferæ. At first these are grey; then they become green, and are half an inch long when mature. They feed under the leaves, and when the leaves are touched they fall by a silken thread and hang in the air. Maturity is reached in four to five weeks, and pupation takes place in a network-like cocoon on the defoliated leaf-stalk, the pupa being black and white. Winter is passed in the pupal stage amongst dead foliage, including that of cruciferous weeds.

TREATMENT.—Spray with arsenate of lead, or draw branches of broom or birch between the rows to knock off the larvæ, and trample them underfoot.

Earwigs (*Forficula auricularia* and *Labia minor*).—Earwigs are of two kinds: those which are common flyers—the SMALL EARWIG (*Labia minor*); and those that do not fly as a rule—the LARGE EARWIG (*Forficula auricularia*). They all have four wings, the first pair being small stumps, beneath which the large membranous wings are complexly folded up. These insects will often feed upon the blossoms of dahlias, violas, and other plants, also upon ripe fruit and hop leaves. They mostly feed by night and hide away during the day under any shelter. The female lays her eggs in little nests in the soil, or under the bark of trees, and the young, which are similar to the parents but white, are attended by the mother for some time. They grow into the adult by moulting their skins, and gradually darkening in colour.

TREATMENT.—Place a pot filled with moss and horse dung, hay, straw, or paper, on a stick where they are working, and the insects will be attracted there during the day, when they can be caught and put into boiling water. Heaps of rubbish (straw, paper, etc.) may be thrown on the ground where they are doing harm and burnt during the day.

Eelworms (*Anguillulidæ*).—These are almost microscopic white eel-like creatures, many of which are parasitic in plant tissues. Some attack roots and stems, such as the EELWORM ROT in peas and beans, etc. (*Tylenchus devastatrix*), or onions, and many flowering plants. Others penetrate into the foliage, such as the FERN-LEAF EELWORM (*Aphelenchus oleisistus*); another produces the CAULIFLOWER DISEASE OF STRAWBERRIES (*Aphelenchus fragariæ*). Others still produce galls, such as KNOT ROOT, which see. They all lay their eggs in plant tissues, and when the plants decay the worms and any unhatched eggs pass to the soil, which may quickly become impregnated with them. They enter the rootlets, etc., by means of a fine boring spine. Attacked plants often show crinkled leaves, and the invaded parts decay more or less rapidly. The wounds caused by the pest also let in various fungi and bacteria.

TREATMENT.—Sterilise all soil used for potting or in smaller beds by heat. Do not grow the same crop two years running if attacked. Dress attacked land with lime, or with one or other of the stronger soil fumigants (see article on *SOIL FUMIGATING*).

Felted Beech Coccus (*Cryptococcus fagi*).—This is a naked scale insect which forms white mildewy-looking wool on the trunk and branches of the beech, and which any time may kill very large trees. The insects breed and grow beneath the felted grey or white mass. They live by sucking out the sap.

TREATMENT.—Scrub the attacked tree, if an ornamental one, with soap and water and a hard brush, or

spray with paraffin emulsion or caustic alkali wash in winter.

Flat Body Moths (*Depressaria Spp.*).—Sometimes the larvæ of the so-called Flat Body Moth do harm to carrot plants for seed; they draw the tip of the flower heads together with silk and feed upon the flowers and seeds. They are greenish to yellowish-grey, with black spots and faint streaks along the back, and are half an inch long when mature. They pupate either in the flower heads or bore into the stalks. The moths are three-quarters of an inch in wing expanse; the wings lie flat over the body; the fore-wings are dusky reddish-brown freckled with white and with dark streaks; the hind wings being grey. The head and thorax are reddish-brown and freckled with black. Another larger species attacks parsnips.

TREATMENT.—Cut off all webbed heads or blow hellebore over the seed heads which are only slightly affected.

Fruit Bark Beetles (*Scolytus rugulosus*, etc.).—These are small beetles about a tenth of an inch long, and of a shiny pitch-black colour, which attack the bark of fruit trees. They bore into the bark, and the females form galleries, and lay eggs there. The small white footless maggots eat away galleries at more or less right angles. Later the larvæ pupate and the adults or beetles escape by numerous small openings which have the appearance of shot holes. The trees are often killed by this pest.

PREVENTION AND TREATMENT.—Destroy all badly attacked trees in winter, and well manure all neighbouring trees so as to produce a flow of sap and thus kill the larvæ.

Garden Swift Moth (*Hepialus lupulinus*).—This is a very active evening and night-flying moth about an inch in wing expanse. Its colour is brown, and it has white markings on the front wings. The moth lays her eggs late in May and June whilst in flight. The caterpillars, which are a dull white, feed upon the roots of mint and many other plants all the winter, and do great damage. They have typical caterpillar legs, also a brown head, and are very active, wriggling violently whenever exposed. In the spring they change to brown pupæ.

TREATMENT.—Clear the ground by using naphthalene or other soil fumigants (see article on *SOIL FUMIGATING*).

Goat Moth (*Cossus ligniperda*).—The large caterpillars of this moth tunnel into apple, ash, oak, pear, willow, and other trees, eventually killing them. The moth is large and heavy, the female reaching three and a half inches in wing expanse, while the male's wing expanse is between two and three inches. The body is large and hairy, and when the wings are expanded reaches much below them. The fore-wings are dark grey and brown, with dusky transverse streaks, the hind-wings being grey to greyish-brown with small darker markings. The moths occur in June and July, the female laying her eggs on the trees. The caterpillars when full-grown are three to three and a half inches long, and are deep dull ochre-yellow, with a broad stripe of a rich mahogany-red down the back. They feed in the trees for three years and then change to brown pupæ in cocoons of wood chips, pupation taking place in May.

TREATMENT.—When trees worth saving are attacked, insert a piece of stick cyanide in the holes and close with clay. Burn all dead timber attacked by the moth as soon as cut down.

Gooseberry Sawfly. See CURRANT AND GOOSEBERRY SAWFLIES.

Green Fly. See ROSE APHIDES.

Heart and Dart Moth. See under SURFACE LARVÆ.

Knot Root (*Heterodera radicicola*). —This well-known disease in cucumbers, melons, and tomatoes is due to minute Eelworms—microscopic creatures which invade the roots and cause them to swell up into fantastic growths, when death soon follows. The male worm is cylindrical, but the female is citron shaped.

TREATMENT.—Sterilise all soil used in the houses by heating it up to 200° F. Destroy all galled roots by complete burning (not charring). Use strong soil fumigants (see article on *SOIL FUMIGATING*), which will do a certain amount of good.

Lackey Moth (*Clissiocampa neustria*).—The caterpillars of this moth live in colonies under and on silken tents on fruit and other trees and in hedges; they are often a foot long. Large plantations of fruit trees are often completely defoliated by them. The caterpillars when mature are one and a quarter inches long; they are lined with brilliant colours on a dark and blue ground and have rusty hairs. The heavy bodied moths are shades of reddish and yellowish-brown, with a pale line or lines across each fore-wing. They occur and lay their eggs in September in rings, without any hair, on the current year's growth of wood, the eggs hatching in May and June. When mature the caterpillars spin cocoons of silk amongst the foliage, etc., in August.

PREVENTION AND TREATMENT.—Destroy all "nests," either by cutting down with long handled shears or even shooting down with a gun. Spray with arsenate of lead where the nests cannot be removed. See that all egg-rings are destroyed when pruning.

Larch Aphis (*Chermes abietis-laricis*, etc.).—The white fluffy growth seen on larch needles is due to several species of Aphis. One species migrates to the spruce, where it forms pine-apple-shaped galls.

TREATMENT.—Spray the spruce in the winter with paraffin emulsion, and if any special larch trees are attacked spray them also.

Larch Sawfly (*Nematus erichsoni*). —This is a sawfly the larvæ of which do considerable harm to the larch trees in the north of England. It is nearly an inch long, and has a wing expanse of a little less than an inch. Part of the abdomen is red, black, or tawny at apex, though the general colour is black; the wings are glassy and are slightly clouded below the stigma. The flies lay small white eggs at the base of young larch leaves, and the caterpillars devour the foliage during the summer, especially in July and August, and leave the trees at the end of the latter month. The larva when full grown measures three-quarters of an inch long; it is grey-green above, and paler at the sides, while underneath it is yellowish-green. The larvæ have twenty legs, and when fully fed leave the trees and pass on to moss and litter, or down to the soil below, there spinning cocoons in which they pass the winter. In the spring or summer they pupate, and the Sawflies soon hatch out. Larch trees are liable to attacks until they are seventy years old.

PREVENTION AND TREATMENT.—Kill all clustered larvæ by hand, or jar them off the trees and trample underfoot. Spray the trees with arsenate of lead, burning litter in the winter below attacked trees.

Leather Jackets (*Tipulidæ*).—The Daddy Long-Legs or Crane Flies that we see too often are the parents of larvæ that do so much

damage in the soil, called "Leather Jackets." These grubs when mature are slightly over an inch long, and about as thick as a goose quill. They have a wrinkled, brownish, rather tough skin, a well-marked head, which can be retracted into the body, a blunt tail-end with short finger-like processes around it and no legs. They feed on the roots of nearly all plants, and may be found all the year round just under the soil surface. The Daddy Long-Legs itself needs no description for it is obviously well known. When mature, the Leather Jackets change to brown chrysalids, which can be told by two horns in front and many backwardly projecting spines on the body. When the time comes for the flies to hatch, the pupæ by means of the spines push their way out of the soil; the Crane Flies emerge and are soon ready to lay eggs.

PREVENTION AND TREATMENT.—Leather Jackets, unlike Wireworms, can be easily killed by digging in naphthalene at the rate of 2 cwt. to the acre. Gaslime is valuable and should be used when obtainable. Various other soil fumigants, indeed most of those referred to in our article on *SOIL FUMIGATING*, will destroy them, and many of the grubs may be caught in gardens by placing turf upside down on infected land, after which the attracted larvæ are destroyed by hand.

Lettuce Root Aphis (*Pemphigus bursaria*).—A white fluffy material is often seen on the roots of old and late sown lettuce plants. This is due to the POPLAR GALL APHIS, (*P. bursaria*), a migration taking place annually between poplars and lettuce.

TREATMENT.—Dig in naphthalene and destroy at once all attacked roots. Never leave them in the soil, as is so commonly done.

Little Ermine Moths (*Hyponomeutidæ*).—These are small moths with satiny-white or leaden grey fore-wings on which are numerous small black dots; and with darker hind-wings, and longish fringes. Their caterpillars live in colonies under tents of silk, where they spin their cocoons. Winter is passed as eggs or newly hatched larvæ under a small resinous covering on the young wood. One species attacks apple, hawthorn, and pear trees, another Euonymus.

PREVENTION AND TREATMENT.—Cut off all nests and burn. Spray with arsenate of lead in the summer, and with caustic alkali wash in winter, to destroy egg-covers.

Magpie Moth (*Abraxas grossulariata*).—This is a moth with a two-inch wing expanse which is creamy-white and spotted or banded with black and yellow. It occurs in July and August, when the female lays yellow oblong eggs on the leaves. Little pepper-and-salt caterpillars come forth very soon and feed until the late autumn; then they hibernate amongst dead leaves, etc., and commence to feed again in spring. By June they are full grown and reach one and a quarter inches in length, when it will be noticed they are black spotted on a white ground, with orange marking at the sides. The pupa is black, banded with orange, and occurs in a loose cocoon of silk amongst the leaves.

TREATMENT.—Spray in the early spring with arsenate of lead and destroy all winter shelter, such as dead leaves, etc.

Marguerite Fly (*Phytomyza affinis*).—This is a small fly similar to a small House Fly. It is dark in colour, about a tenth of an inch long, and occurs in May and June, when it lays its eggs in the leaves of chrysanthemums. The footless

maggots bore a narrow tunnel which appears pale in the tissue of the leaf, and these change to seed like brown puparia. Several broods are possible each season.

TREATMENT. — Spray frequently with nicotine and soap wash.

Mealy Bugs (*Dactylopius longispinus*, etc.).—These are naked scale insects which attack vines and many hothouse plants. The females are apterous, and covered with white meal and cottony matter, the minute males being pale red and winged. The females lay a mass of eggs covered with cottony material, and these produce the spawn or larvæ which wander about.

TREATMENT. — Paint affected parts with methylated spirit, or nicotine and soap. Fumigate with hydrocyanic acid gas in vineries from time to time.

Mealy Plum Aphis (*Hyalopterus pruni*).—This is an Aphis which migrates between plums, etc., and rushes and reeds. It collects in dense masses under plum and apricot leaves, producing a quantity of honey-dew that falls on and ruins the fruit in the case of the plum. There is no leaf curling, as in the ordinary green PLUM APHIS (*A. pruni*), on which separate notes are given.

TREATMENT.—Spray with paraffin jelly plus 1 lb. of liver of sulphur to every 100 gallons of wash.

Millepedes (*Julidæ*).—These are included with centipedes in a group called *Myriapoda*. Unlike Centipedes, which are garden friends, Millepedes may do much damage. They are elongated and active and have two pairs of legs on all the rings of the body, except for the first three, which have each one pair. Some of them, such as the SMALL SNAKE MILLEPEDE (*Blanjulus guttulatus*), are very harmful to roots of many plants and to tubers. This Millepede is about half an inch long, wirelike and about as thick as a pin. It is of pale dull pinkish colour and has a double row of pink or purple spots down the back. All Millepedes can coil themselves up like an Ammonite, and spend their winter in the soil, the females laying their eggs on the ground. The larger dark kinds mainly feed on decaying vegetation, and thus are not serious garden pests.

PREVENTION AND TREATMENT.—Dress badly infected soil with naphthalene or other soil fumigants (see article on *SOIL FUMIGATING*), and trap by placing in the soil decaying turnips or potatoes, taking these up a few days later and burning them up.

Mole Cricket (*Gryllotalpa vulgaris*). — In glass-houses this pest is sometimes very harmful, and also it is a nuisance out of doors. It feeds upon the roots of all manner of plants, and even upon grass. The adults are nearly a couple of inches long; they are of a brown colour, with curious broadened anterior legs and two tails. Tunnels are made by them in the soil, the females making their egg nests sometimes as deep as 10 ins. below the surface. One female will lay over three hundred eggs. The young are like the adults in form, and to some extent resemble ants, but they do not move so rapidly. Their habits are chiefly nocturnal, and it is at night that they come forth and eat the plants, but even by day they devour roots.

TREATMENT.—Pots baited with meat may be sunk in affected borders, level with the soil. If their burrows can be traced they may be destroyed by pouring in boiling water, or by burying naphthalene. When much ground is infected carbon bisulphide injections will be necessary, or other

strong soil fumigants will need to be used. (See article on *Soil Fumigating.*)

Mushroom Pests.—Numerous insect and allied pests attack cultivated and wild Mushrooms, including Woodlice (see later); maggots, the larvæ of Midges (*Sciara Sp.*), also Rove Beetles (*Quedrus*). Dung Beetles (*Aphodius Spp.*) and Springtails (*Aptera*) likewise do some harm.

Treatment.—Spray the walls, etc., before setting spawn with 2½ per cent. Lysol, and spray the beds themselves before any growth takes place.

Mussel Scale (*Lepidosaphaes ulmi*).—This is a small brown scale, often less than an eighth of an inch long, which is found on the bark, leaves, and fruit of apples, pears, etc. In the winter the scales have eggs under them, which eggs hatch in mid-June into little six-legged larvæ, looking like specks of lime. Later these settle down, plunging their proboscis into the plant tissue, and lose their legs, etc., as they become covered with the scale, which has been secreted by the insect.

Treatment.—Spray with caustic soda wash or lime sulphur wash in winter, and paraffin emulsion at the end of June.

Narcissus Bulb Fly (*Merodon equestris*).—This is a fly of very varied colour, which is hairy and much like a small bumble bee, but much more active, as on sunny days it darts about from place to place. It lays its eggs on various kinds of daffodils, narcissi, and lilies. The maggots coming from the eggs enter the bulbs when the leaves are dying off and destroy them. They may pupate in the ruined bulb or in the soil, and this takes place in the early spring. Much damage is caused by the fly, which is notifiable to the Board of Agriculture.

Prevention.—Never plant any bulbs feeling soft, and in any case soak all bulbs in water for ten days before planting if the maggot is suspected. Flies cannot be dealt with except by catching with a butterfly net. Various baits have been tried, but none seem to be of any value for enticing the insects.

Nut Weevil (*Balaninus nucus*).—This pest is a tawny to chocolate-brown weevil with golden-brown pubescence and a long, curved snout. It is about one-third of an inch long, and lays eggs in the young cob, filbert, and hazel nuts, causing the well-known maggot—a sluggish, white, footless creature, with a brown head. This grub eats out the nut and escapes from the shell by tunnelling a round hole. It then falls to the ground, where, in the soil, it pupates, and comes up in the early summer as the Nut Weevil.

Prevention.—Keep a look out for the weevils, and jar them off on to tarred sacks. Spray with arsenate of lead, and treat soil in the winter with strong soil fumigants.

Onion Fly or Maggot (*Phorbia cepetorum*).—The Onion Fly which produces the "Maggot" in onions is very similar to the House Fly. It lays its eggs on young onions close to the ground in the spring. These give rise to dull, dirty-white, footless maggots, which at first feed freely in the soil on the young onions. Later they become brown puparia in the soil—the chrysalis stage—and in a short time another brood of flies appear. These again lay eggs, and the maggots from them eat into the onions, causing the leaves to wilt and turn yellow, and then the onions rot with a characteristic smell. Winter is

passed in the soil as brown puparia, and some of the maggots may be harvested with the crop, these, of course, hatching out in the store-room.

PREVENTION AND TREATMENT.—Sow the seed under glass, and transplant in spring or use seedling bulbs. Dress young onions in the spring when attacked with a light sprinkling of washing soda, and also use old soot very freely. Pick out and destroy all attacked plants. Sprinkling with paraffin and sand at times does good.

Orchid Borer (*Xyleborus morigerus*).—This small beetle lays its eggs in the aerial roots and stems of orchids. It bores its way in, and the footless white maggots, hatching from the eggs, soon form long tunnels. Their presence can be detected by small round holes the size of No. 16 shot, and the wilting of the part attacked. Dendrobiums are especially liable to attack. The beetle is about a twenty-fifth of an inch long; it is brown and stumpy in form.

TREATMENT.—Cut away all parts showing the round holes, tunnels, etc., inside, and burn them.

Otiorhynchus Weevils (*Otiorhynchus picipes*, etc.).—These weevils are characterised by having no wings, the elytra being firm together. The chief are the CLAY-COLOURED WEEVIL (*O. picipes*), the VINE WEEVIL (*O. sulcatus*), and the PLUM WEEVIL (*O. tenebricosus*). They are large beetles one-third to half an inch in length, with a blunt, short rostrum, also marked elbowed feelers near the end. *O. picipes* is tesselated with paler shades, *O. sulcatus* is dark, and *O. tenebricosus* is black and has reddish legs. The beetles feed upon the leaves, buds, and wood of fruit trees, vines, etc., laying their eggs in the ground; the curved, footless maggots, with wrinkled skin, devouring the roots of all manner of plants, especially strawberries and pot plants. They occur as larvæ and adults during the winter. The beetles are very timid, falling at the least shock or sign of light, and as they feed at night may be trapped.

PREVENTION AND TREATMENT.—Spray attacked fruit trees with arsenate of lead. Band young grafted or young stock with Tanglefoot to prevent bud-eating. In foliage attacks jar the weevils on to tarred sacks in the case of bad attacks.

Oyster Shell Bark Scale (*Aspidiotus ostraeeformis*).—This is a more or less scurfy, grey, round, scale insect attacking various fruit trees, which may reach a twelfth of an inch in diameter. Masses of them get mingled up and deformed, producing a dirty-grey, scurvy coating, especially on the bark of plum trees.

TREATMENT.—Smear thick clay and lime over the attacked trunks, and spray with lime sulphur wash for the upper parts in the winter.

Pea and Bean Seed Beetles (*Bruchidæ*).—Peas and beans are often badly damaged by the maggots of several kinds of beetles, related to weevils, which are mostly small, broad-bodied creatures, seldom more than a sixth of an inch long. In colour they are various shades of brown, with grey or rusty markings. The female lays her eggs in the developing pea or bean pod. The maggot lives inside the pea or bean, pupates there, and remains in the seed unnoticed all the winter. Infected seeds can be told by the small round depressions on the sides, where the maggot comes to the surface to pupate. When the beetle hatches, it eats its way out, leaving behind a round exit hole.

PREVENTION.—Never sow infected seed unless the seed has been soaked

in 1 per cent. carbolic water for some days, or has been fumigated with carbon bisulphide.

Pea and Bean Weevils (*Sitones*).—Too frequently loss occurs amongst early and mid-crop peas owing to damage by these small weevils, which eat out the leaves in more or less regular notches at the sides, and too often kill the whole plants. The weevils are small beetles only a fifth of an inch long which are greyish to clay-coloured, and have three pale stripes on the thorax and stripes on the wing cases. They lay their eggs in the ground, the maggots feeding on roots of peas and beans, and then pupate in the soil. Later they hatch, and the beetles attack the late sown peas, continuing to live until next year. Only one species appears to be epidemic on peas and beans. The clover species are now known to be distinct from this pea and bean pest. These small beetles are very timid, falling at the least shock, and hence are not seen unless looked for carefully. They are earth-coloured beneath, and hence too often escape notice. In dull, cold weather they lie quiet under stones, clods of earth, etc., to protect themselves.

PREVENTION AND TREATMENT.—If the soil is fine the pests can find no protection, so start with a fine tilth. If the soil is rough, spread fine soil from glass-houses over the attacked rows. If not, a heavy dressing of soot and road dust will be equally effective, especially if a little paraffin is added.

Pear Leaf Blister Mite (*Eriophyes pyri*).—This is a small mite which enters the pear leaves and causes first pale then black spots, and then dying leaves. It is somewhat similar to the BIG BUD of currants, which see. It may also attack young fruit of both apples and pears and ruin it. Although it spreads slowly, it may do much harm. It winters in the buds under the scales.

TREATMENT.—Spray in the winter with lime sulphur wash, and in the spring with paraffin emulsion.

Pear Leaf Blister Moth (*Cemiostoma scitella*).—This is a small moth a quarter of an inch long, and of leaden-grey colour; it has a darker streak along the front wings, also a coppery band and black spot with violet pupil and darker lines at the apices, its hind wings being leaden-grey. The larvæ eat out round patches (blisters) in apple and pear leaves, which look like dark spots, and when mature leave the blisters and spin up in crevices in the bark and in the soil.

TREATMENT.—Hand pick the first attacked leaves and spray with arsenate of lead.

Pear Midge (*Diplosis pyrivora*).—One of the most disappointing things regarding pears is to find young fruitlets growing away rapidly then failing. If they are cut open one finds them full of small white maggots. These are larval Pear Midges—the young of a small, two-winged black fly, which by means of her long egg-laying tube places her eggs deep in an unopened blossom. When full grown the maggots escape from the galled pearlet and pupate in the soil, hatching out in the following year about the time the pear blossom commences to show.

PREVENTION.—All that can be done is to pick off all swollen, galled fruitlets and burn them, and to keep hens and chickens under attacked trees or in orchards.

Pine Beetle (*Hylurgus piniperda*).—This is a small beetle one-fifth of an inch long and somewhat dark in colour. It is often very harmful to the young shoots of Scots Pine. The beetles hibernate in the rough bark and burrow into it. They then eat out exit holes, surrounded

by a ring of hard resin. Some hibernate in the shoots, which fall with the insects in the autumn. They commence to breed in early March or April. The female lays her eggs both in healthy and sickly trees, and in those felled during the previous year. The larval tunnels, which arise from the mother gallery made by the female and are often 3 ins. long, are at first threadlike, and then gradually widen out, at more or less right angles to the mother gallery. These galleries are made in the bark and not the wood. The beetles escape from holes eaten through the bark—the so-called "flight holes." Those from the second brood, and late swarmers from the old burrows, bore into the young leading shoots, enter the pith, and kill the shoots, which fall to the ground in the autumn, and often cover the soil in pine woods.

TREATMENT. — Destroy breeding places in the stems of cut trees or unhealthy ones. Keep woods free from all brushwood and remove dead trees at once.

Pine Weevil (*Hylobius abietis*).—This is a dull black weevil, with pale yellowish spots on the wing-cases forming irregular bars. It also has some yellow spots on the thorax, a stout rostrum with elbowed feelers at the end, and varies from one-third to half an inch in length. It is injurious in the perfect state alone, and eats the needles and shoots of young and even old conifers, but especially those four to seven years old. The bark is eaten as if by rabbits. The pest, which may be found in all stages during the season, may even live two years in the beetle stage, and continue egg laying. A single generation takes fifteen months to complete. The weevils appear in "swarms" during April, the eggs being laid on the roots of trees felled a year or so previously, and on stumps, where winding galleries are made.

TREATMENT.—Destroy all stumps and roots when felling. Place pieces of fresh bark on the ground, the outer bark upwards, to catch the beetles. Collect and destroy beetles by jarring-off on to tarred matting. Make trenches to prevent beetles from reaching a newly felled or newly planted area.

Pith Moth (*Blastodacna vinolentella*).—This pest is a small moth whose larva penetrates into the shoots of apple, pear, and probably also hawthorn, causing the death of the shoots. The larva winters at the base of a bud forming a brown blister like a "Canker" scar, but has a round hole in it. In the spring the small caterpillar eats up the growing shoot as the side bud grows out, and kills it.

TREATMENT. — Only bush trees seem to be attacked and locally; all flagging shoots should be taken off. During winter pruning see that all blistered areas are cut away and burnt.

Plum Aphis (*Aphis pruni*).—This is a small green Aphis which curls up plum leaves, and often causes them to fall. It winters in the egg stage on plums, laying small shiny black eggs near the buds in the late autumn.

TREATMENT. — Spray with lime and salt wash just before the blossom buds open.

Plum Red Grub (*Opadia funebrana*).—This is a small chestnut-red larva which feeds inside ripening plums and damsons, with typical pro-legs like the CODLING MOTH, which see. It leaves the plum and spins up a cocoon on the bark of the trees and amongst grass, etc., beneath them. The moth, which appears in June and July, laying her eggs at the base of the plums, is half an inch in wing expanse;

its fore-wings are purplish-grey clouded with smoky-grey.

TREATMENT.—Band as for CODLING MOTH, which see.

Potato Stem Moth (*Hydraecia micacea*).—This moth, with wing expanse of one and a half inches, has pale brown fore-wings tinged with a rosy hue, and a broad dark patch below the upper border, between the inner line and the elbowed line; its hind-wings are whitish-grey with a darker central line. It appears from August to October, and lays eggs on a variety of plants, and in gardens and allotments, especially upon potatoes. The caterpillar eats up the haulm, soon killing the plants; holes into the stem are noticeable, from which "frass" is pushed out. Pupation takes place in the soil, the insect remaining in that state all through the winter and spring.

TREATMENT.—Cut off and burn with the caterpillar in it all pieces of flagging haulm.

Radish Fly (*Anthomyia radicum*).—This fly is similar to the ONION FLY, which see. Its larvæ attack roots of various crops, including radishes and others. They are footless yellowish-white grubs, pointed in front, and greatly resemble the Onion Maggot.

TREATMENT.—An entomologist states that if the plants are attacked they should be watered once a week with the following: Add a quarter of a pint of crude carbolic acid and a quart of soft soap to a gallon of boiling water. Mix with a force pump, and add to twenty-five gallons of water. Naphthalene will do much to clear infected land if dug in freely.

Raspberry Maggot or Beetle (*Byturus tomentosus*).—This small beetle is about one-sixth of an inch long and is brown in colour, with a dense golden-brown coating when fresh. It occurs when loganberries and raspberries come into bloom, and lays its eggs in the blossoms. The maggots get into the young-forming fruit and live in and around the receptacle, quickly spoiling the fruit. They are yellowish, and have brown marks in the middle of each segment. They are not more than one-third of an inch long, and at the tail end are two curved projecting points. When mature they fall to the ground or get into holes in the cane or pole to pupate for the winter.

PREVENTION AND TREATMENT.—Jar the canes on to tarred boards to catch the beetles, especially when they are seen to be laying their eggs. Cut and clear out all old growth.

Raspberry Shoot Borer (*Lampronia rubiella*).—This small moth is half an inch across the wings, the front pair of which are shiny brown with yellow spots, the hind pair being grey. It occurs at the end of May, and lays its eggs in the flowers, the larvæ feeding in the core of the berries. They leave these before ripe, and fall to the ground, and shelter in a small white cocoon under the rind of the canes, etc., all winter. In the spring they enter the shoots and kill them. The larvæ which pupate in May are red and have a black head; they are about a quarter of an inch long.

TREATMENT.—Cut back all canes after an attack. Apply soot and lime round the stocks in winter. Smear grease over canes in March.

Raspberry Weevil (*Otiorhynchus picipes*).—This is a blunt-snouted oblong weevil, mostly pitchy black in colour, with some parts light brown and ashy, its brown and yellowish-brown scales giving a tessellated appearance. When old the scales are rubbed off. It appears in May in greatest numbers, and eats the foliage and buds of all manner of plants. It lays eggs in the soil and

the white footless maggots feed on rootage of raspberries and strawberries, pot plants, etc., pupating in the soil. The beetles only work at night and are very timid, falling on the least jar or flash of light.

TREATMENT.—Spray with arsenate of lead or jar the beetles off at night on to tarred sacks. Treat the soil with soil fumigants such as naphthalene.

Red Spiders (*Tetranychus* and *Bryobia*). — Fruit trees, especially gooseberries and vines, are often attacked by these small mites, which are only just visible to the naked eye. To some extent apples also are attacked, and many greenhouse plants. There are two main kinds, of which the best known is *Tetranychus*, which spins a fine webbing under the leaves, laying its eggs in summer under the webbing, when many broods may occur. The *Bryobias* lay eggs in autumn on the wood and buds of the plants they infect; and small round red bodies hatch in March. The colour may vary from transparent white or green to dull red.

PREVENTION AND TREATMENT.—Fruit trees and bushes which have been attacked should be sprayed in the winter or very early spring before the buds open with caustic soda. In the spring the mites may be killed by spraying with paraffin jelly to which 4 oz. of liver of sulphur to each 25 gallons of wash has been added. Vineries and hot-houses should have frequent and copious syringing with plain cold water or be fumigated with nicotine, sulphur, etc. See article on *FUMIGATING*.

Rhododendron Bug (*Stephanitis rhododendri*).—Undoubtedly this is a very beautiful flat-shaped bug with delicate white network-like wings. It lays its eggs on Rhododendrons, the young sucking the leaves and turning them a rusty colour. Many globules of liquid exude and the foliage is quickly spoilt. It is an introduced and serious pest where it occurs.

TREATMENT.—Spray with paraffin jelly as soon as noticed.

Rose Aphides, or Green and Red Fly (*Aphididæ*). — Three Aphides or Green Fly attack the rose, the chief being *Macrosiphum rosæ*—a green and red Aphis, with black honey tubes, which often smothers the tips of the shoots, leaves, and blossoms. It also lives on the teasel, and may invade roses from that. Young are produced in numbers, and now and then alate females occur and fly to other roses, etc. Another attacks roses, wheat, and grasses (*M. dirhodum*), and a third (*M. rosarum*) seems to live permanently on the rose. All winter mostly in the egg stage, though living females of the first may be found all the winter.

TREATMENT.—Spray with nicotine and soap wash, or quassia wash, as soon as the winged (alate) females are seen on the bushes.

Rose Grubs (*Tortricidæ*).—Several Tortrix moths lay their eggs on roses and produce the common ROSE MAGGOTS, which eat and spin together the leaves, tips, and blossom buds, often completely spoiling the first blooms. They are small moths, seldom more than three-quarters of an inch across the wings. The maggots have six jointed legs in front, and four pairs of sucker feet. They pupate amongst the foliage. Some maggots are dull red (*Pardia tripunctata*), some are brown (*Spilonota roborana*), while others are green (*Tortrix ribeana*), or maybe yellow (*Craesia holmanniana*).

TREATMENT.—Spray with nicotine and soap wash, or kill by hand in small gardens.

Rose Sawflies (*Blennocampa pusilla*, etc.). — Several Sawfly

larvæ damage roses. The two worst are the LEAF ROLLER (*B. pusilla*), and the ROSE SLUGWORM (*Eriocampa rosæ*). The larvæ of the first cause the young leaves to roll inwards at their edges, especially in Maréchal Niel; the latter skeletonise the foliage in the same manner as the PEAR SLUGWORM. See under SLUGWORM below.

TREATMENT.—Destroy the first by hand picking. The other pest may be controlled by spraying with arsenate of lead.

Shoot and Fruit Currant Moth (*Incurvaria capitella*).—This is a small moth over half an inch in wing expanse; its fore-wings are brown, and each has a yellow bar and two spots on them. The young larvæ eat into the fruit, and then hibernate. In spring they enter the tips of the shoots, which they quickly kill.

TREATMENT.—Pick off all flagging shoots and spray in winter with caustic soda wash.

Slugs and Snails (*Limacidæ* and *Helicidæ*).—Both these do considerable damage in the garden, especially to seedlings, beans, lettuces, peas, and young Brassicæ. The grey FIELD SLUG (*Agriolimax agrestis*) is one of the worst, and like all slugs has a small hidden shell. All slugs secrete slime and lay their oval eggs in the soil, the young being similar to the adults. They feed mainly at night, but sometimes in the day in dull showery weather. Winter is passed in the soil and under rubbish.

Several snails attack garden plants, notably the LARGE GARDEN SNAIL (*Helix aspersa*) and the SMALL BROWN or STRAWBERRY SNAIL (*Hygromia rufescens*). Unlike slugs, they all have a shell into which they can completely withdraw themselves. Snails lay round eggs in groups in moist soil and under boxes, boards, etc. The young resemble the adults, but the shells are at first very frail. Snails usually pass the winter in a dormant state, covering the entrance to their shells with a lid; many are often stuck together in a mass, in rockeries and at the foot of walls, etc. Both kinds have a rasping tongue by means of which they gnaw the tender parts of plants.

PREVENTION AND TREATMENT.—Dig naphthalene into infected land. Dress heavily attacked plants with soot and lime in wet weather. Heaps of bran mash poisoned with arsenic will kill many slugs, and many patent slug traps are also effective. Collect all winter masses of snails and crush. Protect and encourage thrushes.

Slugworm or Pear and Cherry Sawfly (*Eriocampa limacina*).—This is a slug-like larva which eats the upper skin of pear and cherry foliage, especially in the autumn. The adult Sawfly appears first in May, and lays a single egg in each leaf from below, and the presence of the eggs is told by a small pale speck in the leaves. The larva escapes on the top of the leaf and soon becomes covered with slime. In form it is very marked, being much swollen at the head end, and it has twenty legs. In four weeks it reaches half an inch in length, and then becomes dry and yellowish, falling to the soil to pupate. In the summer this stage lasts a fortnight or three weeks; in winter for a much longer time.

TREATMENT.—Spray attacked foliage with arsenate of lead, or dust with fine lime.

Small Apricot and Vine Moth (*Batodes angustiorana*).—This is a small Tortrix Moth which feeds upon many fruit trees and now and then may do some harm, especially to apricots, pears, and vines by devouring the foliage and curling it up in the caterpillar stage. The moth occurs from June to

August and is about half an inch in wing expanse; it has red-brown to ochreous-brown fore-wings with reddish-brown markings. It lays its eggs on the twigs, and these hatch in spring. The larvæ are greyish to yellowish-green, and are marked with small pale spots from which hairs arise; their length is about half an inch. The larvæ are noticeable from April to June, and pupate in the tubular leaf chambers.

TREATMENT. — Spray with nicotine and soap wash, or with arsenate of lead.

Social Pear Sawfly (*Pamphilus flaviventris*). — The orange-yellow larvæ of this Sawfly live under a tent of silk on hawthorn, pear, etc., and do much damage. They have black heads and three pairs of yellow clawlike legs, but no prolegs; they have also two spines at the end of the body and are about an inch long. By August they are all mature and pupate in the soil. The Sawflies appear in May and June, and lay their yellow eggs in groups on the leaves. The female is black, with yellow legs, part of its body is tawny, and there are yellow marks on each side. The male has a reddish-yellow abdomen; the fore-wings having a dusky bar across them.

TREATMENT.—Cut off the tents, or spray with arsenate of lead.

Surface Larvæ (*Noctuids*).—Caterpillars of the HEART AND DART MOTH (*Agrotis exclamationis*), the TURNIP MOTH (*A. segetis*), and the YELLOW UNDERWING MOTH (*Typhaena pronuba*) are very destructive in the soil to all manner of plants. These caterpillars are dull coloured, of various shades of brown, brownish-grey, and dirty green, with darker lines along the body and dull greenish beneath.

They have six true legs in front and four pairs of sucker feet with an anal pair. When mature they are about an inch long. They feed just under the soil by day, but at night crawl out and cut off leaves, which they may pull into the ground, as well as devour the tissue. In some years much damage is done by them, and their evil working goes on from the summer to next spring. When mature the larvæ change to smooth brown chrysalides in the soil. The first two moths have brown fore-wings with various darker markings and pale hind-wings; the Yellow Underwing has the hind-wings of dull ochreous-yellow with a dark band near the edge.

PREVENTION AND TREATMENT.—Trap the larvæ by placing heaps of bran mixed with arsenate of lead. Dress infected land when digging with naphthalene, applying 2 cwt. to an acre. Frequent side hoeing does good; any grubs which are turned up can be crushed, and many go to the birds. Hand picking the grubs from the soil by scraping them out when working along any row of plants is well worth while.

Thrip or Black Fly (*Thripidæ*).—These are very minute black active insects when mature, with four very narrow wings with long fringes and weak sucking mouths. They feed upon leaves and pods and blossom, often doing much harm in the adult and larval stages. The larvæ are yellow or orange in colour, with six legs, and can run rapidly. They do most harm. One form is very bad on peas, attacking the pods and blossoms; another attacks scarlet runners; while still others attack many greenhouse plants. They lay their eggs in slits cut in the blossoms and leaves, and hibernate at the roots of grass or amongst rubbish. Several species of Thrips also

damage apples, pears, and plums, destroying the buds and blossoms.

PREVENTION AND TREATMENT.—Dress land with soil fumigants and spray attacked plants with nicotine and soap wash.

Tiger Moth (*Arctia caja*).—This large moth is two and a half inches across the wings. Its front wings are creamy, with large black areas, while the hind are bright red, with five black spots. It has a dark head and thorax, also a red abdomen with black bars on it. The caterpillars are called WOOLLY BEARS; they are large, very hairy, dark brownish-black or rusty-red in colour. They feed on strawberry plants and other garden plants, but are of little economic importance.

TREATMENT.—Collect by hand, if abundant.

Turnip and Cabbage Gall Weevils (*Ceutorhynchus sulcicollis*).—Turnips, swedes, and cabbages are often found to have round swellings on them. These are caused by the maggots of a small weevil, called the GALL WEEVIL, which is a beetle one-eighth of an inch long. In colour it is blackish, and is covered with a fine grey or white dusting, most pronounced below. It has a long curved snout and elbowed feelers. The female lays her eggs on and in the roots, and from them come the footless white grubs we find in the galls. When mature the maggots eat their way out of the galls and pupate in the soil.

PREVENTION AND TREATMENT.—Avoid planting any young stock showing signs of galled growth; and avoid planting Brassicæ on land that has been invaded for two years. Dig in naphthalene or other strong soil fumigant and trench vacant ground.

Turnip Flea Beetle (*Phyllotreta nemorum*, etc.).—This is a small beetle, one-eighth of an inch long. In colour it is shiny black, with a yellow or white line on each wing-case. This, with several other allied beetles, attacks turnips, swedes, and Brassicæ generally. The beetles can at once be told by their skipping movements. They eat the seedling plants, later riddle the leaves and often make it necessary to re-sow several times. They hibernate in the winter, coming out in spring, and at first attack charlock and other cruciferous weeds. They lay their eggs on the soil and under the leaves, the little larvæ mining into the leaves as soon as they hatch. When full grown they fall to the earth to pupate. The egg stage lasts from a week to nine days; the maggot stage from three weeks to a month; and the pupa stage from one to three weeks. The maggots of a closely related FLEA BEETLE (*P. undulata*) live in the soil.

PREVENTION AND TREATMENT.—Grow the plants in a good tilth and rich seed-bed so as to hurry them into the rough leaf. Steep the seed in turpentine or paraffin for several hours and mix with sand before sowing. Smother the young plants with fine road dust, or apply a "dry spray." If late turnips are sown between early potatoes, the fly does not get near the seedlings.

Turnip Leaf Miner (*Scaptomyza flava*).—This small yellowish fly, about one-tenth of an inch long, lays its eggs on turnip leaves, etc. The green footless maggots tunnel into the leaves and may pupate there. They do little harm. If at any time very abundant on special plants spray with nicotine and soap wash.

Vapourer Moth (*Orgyia antiqua*).—The very beautiful caterpillars of this moth are of various colours. They feed upon roses and fruit trees and do some harm. The female moth is wingless, fat, and grey; the

male is winged and is one and a quarter inch in wing expanse, and of a rich chestnut-brown colour. The female lays her eggs on the cocoon spun by the larva, on leaves, outhouses, walls, and such-like.

TREATMENT. — Destroy all egg masses seen, and when the larvæ are prevalent, spray with arsenate of lead.

Wasps (*Vespidæ*).—These often do much damage to ripe or ripening fruit, especially apples, plums, and pears. Two types occur, the GROUND or COMMON WASP (*Vespa vulgaris*), which makes its nest in the soil, and the TREE WASP (*Vespa sylvestris*), and others which form hanging nests in trees, shrubs, kale-pots, etc. These latter are often the most harmful. At the same time we must remember that wasps do much good in early summer by devouring quantities of caterpillars; but the good done does not outweigh the evil.

PREVENTION.—Destroy all queen wasps. Trace nests in soil and fumigate with tar and sulphur or place stick cyanide at night in the nest entrance and close up. Trap with beer and sugar in suspended jars. Shoot down or cut off suspended nests.

Winter Moths (*Cheimatobia brumata*, etc.).—The caterpillars of the WINTER MOTH (*C. brumata*) and allied species, such as the MOTTLED UMBER MOTH (*Hybernia defoliaria*), and the MARCH MOTH (*Anisopteryx aescularia*), attack all kinds of fruit trees and bushes, also roses and forest trees. They are known as LOOPERS owing to their crawling in a series of loops, and also as MEASURERS or CANKER WORMS. The male moths are winged, but the females are quite or nearly wingless. The Winter Moth larva is green with paler and darker lines; the Mottled Umber Moth is rich brown with yellowish side lines, and the March Moth green and thin. These larvæ can be told by having the true six legs in front, only one pair of sucker feet in the middle and an anal pair. The male Winter Moth is an inch across the wings, the front ones brown with darker wavy lines, the hind pair grey. The male Mottled Umber Moth is various shades of yellowish-grey and brown and finely speckled; the March Moth is greyish-brown with paler transverse lines. The females of the last two are entirely wingless, but the true Winter Moth female has little stumpy remnants of wings, useless for flight. The moths emerge from the ground between October and March or even April (March Moth, etc.). The Winter Moth and Mottled Umber Moth lay their eggs singly near the buds, etc.; the March Moth in rings around the year's growth of wood, covered with brown hair. The larvæ feed on buds, foliage, blossom, or fruit, and are all matured by the end of June. They then pass to the soil and pupate there. The eggs hatch just as the buds are bursting in spring.

PREVENTION AND TREATMENT.—Grease band standard and half-standard trees early in October, keeping the bands going all the year round. Spray bush trees and cordons with arsenate of lead, or nicotine and soap wash early in May. Keep poultry when possible in the garden and orchard under the trees. See that all egg bands of the March Moth are cut off and burnt when pruning.

Wireworms (*Elateridæ*). — The larvæ of Click Beetles are the well-known Wireworms, which are often such serious pests in the garden. The adult Click Beetles are brownish and can be told by their curious skipping movements, which are at-

tended by a "clicking" sound. These beetles may be found almost all the year, but mostly out of doors in June and July. They lay their eggs in and on the soil, especially preferring land covered with dense vegetation, such as grass land, cloverley, or where there is much weed growth, but will also lay freely even in clean land. As is well known, wireworms are a shade of yellow or yellowish-brown, and have a hard smooth skin, a brown head, with biting jaws, and a few fine scattered hairs. They have three pairs of jointed legs on the first three rings of the body, and under the tail end is a small rounded process. These larvæ, which may reach an inch in length, live in the soil for three to four years, and even five, feeding most of the time on the roots and tubers of different plants. In cold frosty weather they pass deeper into the soil and thus escape harm. When they are full grown they change in the soil into pupæ and emerge in winter or spring, and later come up as perfect Click Beetles.

PREVENTION AND TREATMENT.—The damage done by Wireworms may be prevented by (i) deep and clean cultivation; (ii) the use of stimulating manures; (iii) drilling the manure with the seed; (iv) the growth of crops not attacked to any extent, such as beans, onions, peas; and (v) by digging in naphthalene at the rate of 2 cwt. to the acre, all of which act as deterrents but do not, it seems, kill the insect. Wireworms may be trapped with pieces of carrot, potato, or turnip placed in the ground and lifted weekly. The Click Beetles may be trapped by enticing them to lay their eggs under heaps of clover or lucerne covered with a few tiles or boards. Land badly attacked should have mustard grown on it and green matter dug in. When grass land is dug up the turf should not be taken off but deeply buried.

Wood Leopard Moth (*Zeuzera pyrina*).—This is a moth one and a half to two inches across the wings. It is white, but spotted with deep steel blue on the front wings, with smaller specks on the hind. It occurs in June and July, and its larvæ tunnel into the wood of the apple, cherry, chestnut, pear, plum, etc., and especially into the small branches.

They are yellowish-white, spotted with black, and after ten months of life reach two inches in length. They then spin silken cocoons covered with bark chips in which they change to brown pupæ.

TREATMENT.—Cut off and burn all small branches seen to be flagging, down to the end of the black tunnel, formed by the caterpillar. If the attack is low down, place pieces of potassium cyanide in the holes as for GOAT MOTH.

Woodlice (*Omiscidæ*). — These creatures, which are related to crabs and lobsters, are often called MONKEY PEAS, SLATERS, and SOW-BUGS. They breathe by means of little gills attached to the base of the legs, and some can curl themselves up into a ball. They damage seedlings, and are often harmful in frames and in mushroom pits. They love moisture and are mainly nocturnal, hiding away amongst any rubbish and in crevices all day. The young are very similar to the adults.

PREVENTION AND TREATMENT.—Trap by placing flower-pots half-filled with moss and fresh horse manure on their sides; they collect there and so are easily caught. Remove all rubbish from, in, and around frames. When frames are cleared pour plenty of boiling soap and water into the crevices.

Woolly Aphis, or AMERICAN BLIGHT (*Schizoneura lanigera*). — This is an Aphis which lives on the roots, trunk, branches, shoots, and foliage of the apple and elm. It produces a quantity of white flocculent wool. By means of the constant puncturing of the bark or skin galled growths are formed both above and below ground on the apple and thus much harm is done. There is a migration between the roots and trunk, also a migration to elm trees, where the sexual brood occurs and eggs are found during winter. The progeny on the elm becoming winged, fly away to the apples in early summer. They can, however, live and reproduce asexually on the apple alone for many years.

PREVENTION AND TREATMENT.— Keep the trees clean by winter spraying with caustic soda wash. Spray attacked trees with paraffin jelly, or paint the woolly patches with methylated spirits. Dress attacked soil with naphthalene, at the rate of about 2 cwt. per acre, forking it well in at once.—F. V. T.

INSECT PESTS: General Methods of Destruction.—Having described a few of the numerous insect pests which worry the gardener, we give below some notes on the making of various sprays, washes, etc., which are there recommended for destroying the various pests. No good purpose, for instance, could be served by repeating the formula of Paraffin Jelly every time it is mentioned, since it would be mere repetition. Many books might, however, be written on General Methods of Destruction of Insect Pests, so it will be obvious that the few notes that follow might be amplified very much. However, we prefer to describe the ways of making a few of the most important and most frequently employed insecticides, rather than cover many pages in describing the preparation of every wash that is known. Those we describe will cover, it will be found, practically the whole ground, and this being the case, little attention need be paid to the preparation of special washes which are not described in these notes.

In most cases the gardener can obtain the preparations described below ready-made from any reliable horticultural sundriesman, and although in such cases as Lime Sulphur Wash and Arsenate of Lead it is far better to rely on preparations made by experts under chemical supervision, in others the washes may be prepared quite easily and quickly by the gardener himself. Care should, however, be taken to measure or weigh up the various chemicals and liquids referred to exactly, since a small error in such as Arsenate of Lead, or other poisonous chemicals, may lead to serious loss instead of benefit. The gardener will find our article on *WEIGHTS AND MEASURES* useful here.

One point more before we describe the mixtures themselves. There are certain washes highly praised in many gardening books, such as American Paraffin Emulsion, Paranaph, Resin Spray, etc.; these are not included in the present article since they are not of any special value here. Soil fumigants as such, are also excluded, as they receive full attention in our article on *SOIL FUMIGATING*.

Arsenate of Lead.—This is used for killing biting or leaf-eating insects, such as Caterpillars and Beetles. The formula is—

Arsenate of Soda (Com.)	2 oz.
Acetate of Lead	7 ,,
Water	10 gals.

Dissolve the two chemicals in water, and apply as a fine spray. Various commercial "pastes" are on the market, and may be obtained ready for use on being mixed with water. This wash may be used with Bordeaux Mixture.

Caustic Soda Wash.—This is used for cleaning fruit trees, and destroying scale-insects, also the wintering little Ermine Moth larvæ. Its formula is—

Caustic Soda (Com.)	2 lb.
Water	10 gals.

Dissolve the Caustic Soda in a little cold water, and dilute with the remainder. Keep the liquid off the hands and clothes, as it is very corrosive. Apply with considerable force as a spray, not later than the end of February, and never use except on dormant fruit trees.

Hellebore Spray.—Hellebore is an intensely poisonous and strong smelling powder, which is useful as an in-

secticide for Sawfly larvæ where Arsenate of Lead could not be used. It is not, however, nearly so efficacious. The formula of the spray is—

Hellebore Powder	4 oz.
Water	10 gals.

Hellebore should always be dissolved in a little hot water first, and then the mixture diluted to required strength. The eyes, nose, and throat must be protected when using it.

The powder itself may also be used dry as a dust. As a modern insecticide, however, it may be discarded.

Hydrocyanic Acid Gas.—This is used for fumigating glasshouses and fruit trees in order to kill Mealy Bug, Scale, and other insects. The formula is—

Potassium Cyanide (98 per cent. purity)	1 oz.
Sulphuric Acid (Sp. Gravity 1·83)	1½ oz.
Water	3½ oz.

For hardy or dormant plants use 1 oz. of Potassium Cyanide to 200 cubic ft. of space, and for tender plants use 1 oz. of the Cyanide per 500 cubic ft. The method of estimating the cubical air contents of greenhouses is dealt with in our article *ARITHMETIC AND GARDENING*.

As the gas is exceedingly dangerous to human beings, precautions must be taken before adopting this method of destroying pests. Special appliances are thus necessary to enable the house to be worked from the outside, and such can be obtained from horticultural sundriesmen. The house should be as dry as possible, the temperature not exceeding 60° F.

First make the house as air-tight as possible, and pour the Sulphuric Acid slowly into the water, using an earthenware or non-metal jar. Then drop the Cyanide into it, and note that the deadly fumes come away at once. Leave the house sealed up for at least an hour, after which ventilate completely before attempting to enter it. One machine will be needed for each 10,000 cubic ft. of space treated.

Fruit trees, before planting, may be put into small air-tight houses or sheds, and left for at least three hours, to kill Scale, Woolly Aphis, etc., upon them.

Lime Salt Wash.—This is most effectual in the cleaning of orchard trees, and for killing Apple and Plum Aphis. It also checks the Apple Sucker and Apple Blossom Weevil. It is one of the most useful washes of all, since the lime and salt return to the soil, and much improve the health of the trees, so that they are better able to resist disease. The formula is—

Quicklime	1–1½ cwt.
Common Salt	5 lb.
Water	100 gals.

Slake the lime up with water, and then strain through a coarse piece of sacking into the salt and water. Apply as a thick spray any time between late February and the bursting of the buds.

Lime Sulphur Wash.—This is most useful for destroying Scale insects in the winter and summer. It is difficult to mix accurately, and gardeners are advised to purchase it ready-made from any reliable firm.

London Purple.—This is a waste product which contains much soluble Arsenic, and unless lime is added, very serious scorching will take place. We cannot recommend it highly, as its killing power is low compared to Arsenate of Lead, and its evil effects are too frequent. The formula, however, is—

London Purple	3 oz.
Quicklime	3 ,,
Water	40 gals.

Apply as a spray any time during the growing season.

Nicotine and Soap Wash.—This is a most powerful insecticide for the destruction of Aphis, Apple Sucker, Cuckoo Spit, Leaf Miners, and all forms of young Caterpillars. Its formula is—

Nicotine (96 per cent. purity)	1½–2½ oz.
Soft Soap	4 ,,
Soft Water	20 gals.

Pour the Nicotine into the dissolved soap in the water, and apply as a fine spray, but avoid using it on any plants the leaves of which are likely to be cooked or eaten in less than four or five weeks. The same remark applies to fruit.

Paraffin Jelly.—This is most useful for killing Aphis, Leaf Hoppers, Red Spider, and Scale. Its formula is—

Paraffin	5 gals.
Soft Soap	8 lb.
Soft Water	10 gals.

Simmer together in a closed copper, and when boiling add a few pints of water. When all is dissolved pour into a pail or barrel, when it will soon become a thick jelly. The formula used for spraying is—

Paraffin Jelly	10 lb.
Water	40 gals.

This should be applied in the form of a fine spray at any time throughout the growing season.

Paris Green.—This insecticide was much used at one time, but owing to the fact that it frequently produces scorching, its place has long since been taken by Arsenate of Lead. Although it is frequently recommended in many gardening books, no one with any experience advises its use. However, for those who must have it, the formula is—

Paris Green Paste	1 oz.
Quicklime	1 ,,
Water	10 gals.

The paste must be carefully shaken up with a little water, and strained, after which the lime is added. It must be constantly stirred and applied as a fine spray.

Pyrethrum Powder and Spray.—Pyrethrum is used by gardeners for all biting insects both as a wet spray and a dry spray. It may also be used as a fumigant under glass. The formula of the wet spray is—

Pyrethrum Powder	2–3 lb.
Water	10 gals.

The fresh powder is infused in a little hot water for at least 3½ hours. The liquid is then strained off, and added to the full amount of water. When cold the liquid is used as a spray.

The dry powder may be dusted freely over the plants when they are wet with dew.

Pyridine and Soap.—This is chiefly used for killing Cuckoo Spit and Aphis. Its formula is—

Crude Pyridine	4 oz.
Soft Soap	2 oz.
Water	10 gals.

Mix the Pyridine in a little warm water. Add the soap previously dissolved in half a gallon of water. Stir well, and dilute to 10 gals. Apply as a forceful spray as soon as attacks are noticed.

Quassia and Soap.—This most useful simple wash is valuable for Aphis of the non-mealy or woolly sort. Its preparation is described in our article on *Quassia*.

Tobacco Wash.—This is not so reliable as Nicotine and Soap Wash, and as Tobacco Waste is difficult to obtain; the only way one can use any Tobacco Wash in this country is to rely on a commercial firm for making the same. The formula, however, is—

Tobacco Waste	4–6 lb.
Soft Soap	1–2 ,,
Water	20 gals.

The Tobacco Waste is infused in water, and this is constantly agitated. A pinch or two of soda is added, and then the solution is mixed after straining, with the dissolved soap and water.

Woburn Winter Wash.—This useful wash is used for destroying Mussel Scale, and generally for cleaning fruit trees. Its formula is—

Paraffin (Solar distillate)	10 pts.
Iron Sulphate	1 lb.
Quicklime	½ ,,
Caustic Soda	4 ,,
Water	20 gals.

Dissolve the Iron Sulphate in 18 gallons of water, and slake the lime in a little water, adding a little more to make it into a milk. Then run the milk into the dissolved Iron Sulphate through a fine sieve, finally churning up the oil into the Iron Sulphate and Lime, adding last of all the Caustic Soda. Apply as a heavy spray during the winter when the trees are dormant.—F. V. T.

See also *Soil Fumigating* and *Soil Sterilisation*.

INSECTICIDES.—See *Insect Pests: General Methods of Destruction* and *Soap Washes: Their Use in the Garden*.

INTERCROPPING.

There appears to be some doubt as to the exact meaning of the term "intercropping." People confuse it indiscriminately with catch cropping, with rotational cropping, and even with successional cropping. But, very briefly, intercropping is the act of growing one maincrop subject between another.

In the article on *Catch Crops* we saw how to grow quickly maturing crops between those which stand longer upon the ground, and the question that every gardener has to answer for himself before proceeding far into the matter of intercropping is whether it is applicable in his case and in his district or not. Intercropping is a matter on which there are many opinions, and it is doubtful whether it pays in suburban areas, where there is much smoke in the atmosphere or anything else to hinder the proper and rapid development of the crops. Given a

genial climate in the south of England, far away from varnish, steel, soap or other factories, with a warm, light soil, a moderate rainfall, and a little knowledge of the culture of vegetable crops, there is no reason why intercropping should not be the great success we wish. In the absence, however, of these conditions it is better to leave it alone.

If intercropping is to be successful, then the originally intended main-crops must be set at slightly greater distances apart than is usually allowed. No good purpose can be served by crowding, and what is winked at in the case of catch crops must be treated with contempt in the case of intercropping. Savoy cabbages, broccoli, curled greens, maincrop potatoes, cauliflowers, red cabbage, chou de burghley, Brussels sprouts, and kale are all crops which can be grown on the intercropping system. As, however, all of these take up considerable space, if one is to be planted between the other, room must be allowed for their proper development.

One of the greatest essentials in successful intercropping is a rich soil, and if this is non-existent it would be foolish in extreme to tax the already poor soil by growing two crops instead of one at the same time. It would also be foolish to plant one crop between another before the first crop was anything like matured, in the hope that the second crop might get food enough to develop when the first had been taken from the land. Much, however, can be done by the use of suitable liquid animal manures or fertilisers, and certainly for all successful intercropping these liquids must not be stinted. Strong plants are the first essential, and any one who has seen cabbages, etc., struggling for life between rows of main-crop or early potatoes will realise how strong each subject must be. The after care of all intercropped areas is the same as that given to those which are grown in the ordinary way, namely, frequent hoeing and weeding must be carried out, and the crops lifted, cut, or harvested at a suitable time.—E.

INTUMESCENCES.—See *DISEASES OF PLANTS*.

INULA (FLEABANE. Nat. Ord. Compositæ).—This may be said to be a flower of the future. So far there are not a great number of sorts offered by the trade to choose from, nor are the flowers as attractive as some. The plants, however, come in very well for shrubbery borders, sunny spots in the wild garden, or the mixed border, but they are hardly of sufficient merit to be put among one's choicest plants in the perennial border.

Culture.—But little difficulty will be found in growing these even by amateur gardeners and beginners who have no experience of gardening. They may be planted any time from the early winter onwards into the early spring, and are easily propagated by seeds sown in the usual way, or division of the rootstocks; this last operation being conducted in November or February. A position in full sun suits them; we grow ours in a mixed border facing due south. They will thrive in any garden soil of fair quality. If large flowers are required, abundance of water should be applied in hot seasons, and weak liquid manure will also be a decided help.

What to Grow.—We recommend the following:—

Inula glandulosa. — A desirable sort, with golden-yellow flowers. These are produced in July and onwards. The height is about 2 ft.

I. grandiflora.—This large free-flowering yellow sort, blooming from July well into the autumn, is by some

authorities considered synonymous with *Helenium grandiflorum*. Its height is 2–3 ft.

I. Helenium (ELECAMPANE).—This is sometimes mistaken for an *Helenium*. It is a yellow summer-flowering sort, averaging 1 yd. in height.

I. Hookeri.—Probably the most popular sort of all. Its flowers are, as usual, yellow, and are large; they come later than the other sorts, the plant being at its best in August. The height averages rather less than 1 yd.

I. macrocephala. — This useful yellow flowering sort, coming in at the same time as *Inula grandiflora*, appears to be synonymous with *I. royleana*. It averages 3 ft. in height.

I. royleana.—This bears attractive yellow flowers from July to September, and averages 3 ft. in height.

See also ELECAMPANE in *MEDICINAL HERBS*.

IODAME (*Quercus glandulifera*).—See *TREES*.

IONOPSIDIUM.—A synonym for COCHLEARIA. See *VIOLET CRESS*.

IPOMOEA (Nat. Ord. Convolvulaceæ). — This a very large genus composed mostly of climbing plants, the greater part being tropical or sub-tropical perennials. There are a few annual species which need to be grown in a warm house in this country, but the one hardy annual species, *I. purpurea* (Syns. *Convolvulus major*, *C. purpureus*, and *Pharbitis hispida*), is well known in gardens, and the parent of a race of popular summer-flowering climbing plants. Seedlings may be raised under similar treatment to that found successful for half-hardy annuals, but unless each seedling is placed in a separate pot quite early in its career there is likely to be loss and disappointment when planting is done. The expression "hardy" requires a little qualification in regard to *Ipomoea purpurea*—it is nearly, but not quite, hardy in the majority of British gardens. Early May is soon enough to make a sowing out of doors, and late May or early June quite soon enough to plant out seedlings raised under glass. For covering arches, trellis work, and for wreathing windows, this plant, popularly known as the MORNING GLORY, is charming, no matter what the colour of its flowers may be, and the colour range extends from white, through pink, rose, and crimson, to purple, pale blue, and various striped shades. There are double as well as single varieties, but the latter are the most popular. The flowers of both are short-lived, it is true, but so freely produced that this defect is hardly noticed.

The typical *I. purpurea*, and its varieties *elatior*, white and blue, and *varia*, white, striped blue, or pink, were valued in gardens in our great-grandfather's days, and each was figured in the *Botanical Magazine* about a hundred years ago.

IPOMOPSIS.—Now included in the genus *GILIA*.

IRIS.—See *IRISES*.

IRISES (Nat. Ord. Iridaceæ).

The Iris genus is confined to the northern temperate zone and numbers more than one hundred and fifty species, distributed from California in the West to Japan in the East, and from Alaska in the North to Hong-Kong in the South. Many of the species hybridise readily with one another, and a large proportion of the Irises usually seen in gardens are of hybrid origin and not wild species. Most Irises flower in the first six months of the

year, while a few flower somewhat irregularly in the autumn.

BULBOUS IRISES.

1. The Reticulata Section.—All the members of this section have bulbs with outer coats formed of a network of coarse fibres. The so-called type *I. reticulata* is of a deep blue colour with a central streak of orange on the falls, and slender four-sided leaves. It is probably much rarer in the wild state in the Caucasus than its red-purple counterpart, *I. Krelagei*. They both flower in February and March.

I. Histrio from Syria is less hardy and has flowers brightly mottled with two shades of blue, while the still more delicate *I. Vartani* from Palestine has flowers of a pale grey blue with a strong scent of almonds.

I. histrioides from Northern Asia Minor is far more vigorous and has large flowers of a bright steel blue which appear as soon as the leaves pierce the ground. The dwarf *I. Danfordiae* from Central Asia Minor has brilliant yellow flowers.

All the members of the section seem to prefer a good soil, rich in humus, but at the same time warm and well drained. The bulbs should be lifted annually and replanted in fresh ground after a short interval; if left undisturbed, they sometimes increase rapidly, but often fall victims to a fungoid disease. The flowers are stemless, but are raised on long perianth-tubes to a height of 6–9 ins. above the ground.

2. The Juno Section.—These Irises are distinguished by their broad, channelled leaves and by the fleshy tuberous roots that remain attached to the bulb in its resting state. *I. alata* from Spain, Sicily, and North Africa, and *I. palaestina* from Palestine are autumn- and winter-flowering species which unfortunately cannot be relied upon to ripen their growth in this country so as to form flowering bulbs for the next season. Height, 6–8 ins.

I. persica, with flowers of blue-green and brown-purple, is a difficult species to grow except in stiff loam, but well repays any trouble, as do also its near allies *I. Heldreichii* or *stenophylla*, with flowers of two shades of blue-purple, and the red-purple *I. Tauri*. None of these grow more than 6 ins. high.

I. sindjarensis from Mesopotamia grows to a foot or more in height, and needs a stiff soil. It bears pale blue flowers and has produced some beautiful hybrids with the various members of the persica group.

The following species come from farther east in Central Asia and are better suited to a light sandy soil well enriched with old manure and leaf-soil: *I. Rosenbachiana*, with flowers of every shade of blue- and red-purple—height, 8 ins.; *I. bucharica*, a very vigorous grower with white and yellow flowers; *I. orchioides*, wholly yellow; and *I. Warleyensis*, of a rich purple with a conspicuous yellow blotch. The last three species hybridise easily together, and give rise to a number of intermediate forms; height, 12–18 ins., flowering in March and April.

3. The Xiphion Section.—The members of this section are chiefly confined to Spain and Portugal, with outlying members in North Africa and South-Western France. *I. Xiphium*, the wild type of the well-known Spanish Irises, has blue flowers, but has given rise in cultivation to innumerable varieties. Yellow forms are obtained from the nearly allied Portuguese *I. lusitanica*, while *I. filifolia* from the extreme south of Spain and the neighbourhood of Tangier has flowers of a magnificent red-purple shade. The giant *I. tingitana* does not flower freely except in very warm and sheltered

positions. Its bulbs need very rich feeding if they are to become strong enough to bloom. All the above species like a soil that becomes warm and dry in the late summer, but the so-called English Iris, *I. xiphioides*, which is really a native of the Pyrenees, needs a cool, moist position to do well. The wild plant has flowers of a deep blue, but under cultivation has given rise to many varieties of all shades of purple, ranging from the deepest blue to pure white. The members of this section vary in height from 12 to 24 ins., according to soil and position.

NON-BULBOUS OR RHIZOMATOUS SPECIES.

These have a rootstock consisting of a rhizome or underground stem, and are divided into *Pogoniris*, of which the flowers are bearded, and *Apogon* species, which are beardless.

Pogoniris or Bearded Species.—These are perhaps the best known of all Irises. They range from the dwarf *I. pumila*, which sends up its stemless flowers in April, to the 4 ft. high *I. trojana* and *I. mesopotamica*, which do not flower until June. The wild species are confined to Central and Southern Europe and Western Asia. Species and hybrids alike all prefer a good rich soil plentifully supplied with lime, and it is essential that the positions chosen should be well drained and sunny. The plants should be lifted and replanted every two or three years, and the best time for this operation is immediately the flowers have faded, though it may be carried out with success as late as August or even in early September. If the rhizomes are replanted after that date, root growth has practically ceased for the year, and the plants are therefore unable to anchor themselves in the ground before winter. In soil not deficient in lime these Irises are rarely attacked by disease, and the one disease to which the rhizomes sometimes fall victims is easily checked by a liberal application of superphosphate of lime, which should be watered in, if the soil and the weather are dry.

There are many species of bearded Iris, of which some have given rise to innumerable hybrids. Among the more desirable are: *I. pumila*, very variable as to colour in the wild state; of garden forms, *coerulea* is one of the most pleasing, 6 ins., April; *I. Chamaeiris* may be obtained in white, yellow, red-, or blue-purple forms, 6–12 ins., April and May; *I. arenaria*, bright yellow, 4–6 ins., May; *I. aphylla*, with a branching stem and flowers of blue- and red-purple, very hardy and floriferous, 12–18 ins., May; *Caparne hybrids* or intermediates between the foregoing and the later and larger species, 12–18 ins., May. Some of the best are: *Ivorine*, ivory white; *Queen Flavia*, deep yellow; *Don Carlos*, deep blue; *Dorothy*, grey blue; the so-called *Germanica Hybrids*, though it is probable that no such wild species as *germanica* ever existed. Some good forms are *Kharput* (28 ins.), red-purple; *Amas* or *macrantha* (24 ins.), blue-purple; *Oriflamme* (30 ins.), an improvement on *Amas*; *Kochii* (18 ins.), a dwarf dark red-purple; *florentina* (24 ins.), white, tinged with faint blue. Other good plants are: *albicans* (24 ins.), pure white, the albino form of the blue-purple *Madonna* (24 ins.); *pallida* (12–36 ins.), in all shades of blue and red-purple, e.g. *dalmatica* (30 ins.), pale lavender, *Ciengialti* (15 ins.), dwarf blue, *Goldcrest* (26 ins.), a taller blue; *Monte Brione* (30 ins.), red; *Ed. Michel* (30 ins.), red; *Mrs Alan Grey* (24 ins.), *Queen of May* (30 ins.), *Her Majesty* (30 ins.)—all good pinks; *Mme Chereau* (36 ins.) and *Jeanne d'Arc* (30 ins.), white, edged blue and purple; *Prosper Laugier* (36

ins.), *Isoline* (36 ins.), *Alcazar* (30 ins.) — all of mixed and almost indescribable colouring; *Black Prince* (30 ins.), very late, of light and dark blue-purple; *Thorbecke* (30 ins.), white and deep purple; *variegata* (12–30 ins.), yellow with purple and mahogany veining, of which the best forms are *Iris-king* (30 ins.), *Gracchus* (24 ins.), and *Maori-king* (24 ins.); *trojana* (40 ins.), tall and late, with flowers of two shades of red-purple on much-branched stems.

Oncocyclus Irises are a peculiar group of species confined to Asia Minor, Syria, and Persia. They have broad straggling beards and only one flower, often of immense size, on the stem. They are difficult to grow, but so amazing in their shape and colouring as to be well worth the effort. The rhizomes must be planted in October in a warm, well-drained position in strong, rich soil. They should be lifted in July and kept dry till October. *Iberica* (8–12 ins.) is one of the easiest; *paradoxa* (12–18 ins.), *Lortetii* (20 ins.), *Gatesii* (20–24 ins.), *susiana* (24 ins.), *Sari* (15 ins.), *acutiloba* (12 ins.) will all repay successful cultivation.

Regelia Irises are closely allied to the Oncocyclus species. They produce two or three flowers on each stem and, though needing the same treatment as the Oncocyclus species, are quite easy to grow under those conditions. Only three species are commonly in cultivation, but all are worth growing: *Korolkowi* (12–18 ins.), *stolonifera* (12–24 ins.), *Hoogiana* (24 ins.).

Regeliocyclus hybrids between the above groups combine some of the features of both and grow more vigorously. Some of the best are *Charon, Persephone, Sirona.*

Apogon or Beardless Species.— Of these there are a number of groups and some isolated species, several of which have given rise to garden forms.

The *sibirica* group needs cool soil, rich in humus. The best are the type and its albino form, *I. sibirica* and *sibirica alba* (18–36 ins.); *I. orientalis* and *I. orientalis alba* (Snow Queen) (24–30 ins.); *Wilsoni* (30 ins.) and *Forrestii* (18 ins.), yellow; *chrysographes* (18–24 ins.), very rich dark purple with gold veining; *Clarkei* (18–24 ins.), of various shades of purple; *Delavayi* (36 ins.), tall and late, of various rich shades of purple.

Bog Irises are our native *Pseudacorus* (36–40 ins.), yellow, and its American counterpart *versicolor* (24–36 ins.), with a good crimson form *kermesina; laevigata* (18–24 ins.), a rich blue with a pure white form and another spotted with blue (*albopurpurea*); *Kaempferi* (24–36 ins.), the Japanese Iris, with its innumerable varieties, which must have rich soil and moisture.

Many Apogon Irises do well in borders of rich, well-manured soil. Among these are: *spuria* (24–48 ins.), of various shades of purple; *ochroleuca* (36–48 ins.), white and yellow; *aurea* (36–48 ins.), deep yellow; *Monnieri* (36–48 ins.), lemon yellow; *Monspur* (36–48 ins.), a hybrid between *Monnieri* and *spuria.* All these have tall, stiff, narrow foliage and tall stems, bearing flowers of the shape of the Spanish Iris, arranged in a spike one above the other.

I. longipetata (24 ins.), *I. l. montana* (18–24 ins.) (*tolmeiana*), and *Tollong* (24–30 ins.) are an American group of good border plants. The Californian species *douglasiana* (12–24 ins.), *tenax* (12–18 ins.), *Purdyi* (12 ins.), *bracteata* (18 ins.), *macrosiphon* (12 ins.), *Watsoniana* (18–24 ins.) show amazing variety of colour, each individual plant being different. They are, however, not easy to move, but succeed well in

light, rich soil, free from lime. They should be raised from seed and planted out where they are to bloom.

Our native *foetidissima* (18–24 ins.), with lead-colour or yellow flowers, will grow in half-shady places among trees, and its scarlet seeds are decorative in winter.

I. ensata forms huge tufts of foliage, which remain green in the hottest seasons and produce numerous stems with small graceful flowers in May. Its colour is mostly a blue purple, but there are white and dark forms and a Tibetan variety with larger flowers of primrose shaded with blue-grey.

I. ruthenica (6–9 ins:) is a dwarf plant well suited for edges or for growing on a rockery. The best form is very floriferous and bears blue flowers in May.

I. graminea (12–24 ins.) is a good plant for the front of a border and should be grown for the scent of its flowers, which is like that of a ripe greengage.

I. unguicularis (*stylosa*) is one of the most valuable of winter-flowering plants and should be given the best available position, close against the foot of a south wall, by preference against the wall of a greenhouse, where it will be helped by the warmth from within. It should be planted in early September in rather poor soil with some lime rubble and then left undisturbed. Each autumn the old leaves should be cleaned from the clumps, which must be carefully searched for slugs and snails which take refuge in them and eat the buds. No stem is produced, but the perianth-tube grows to a length of 6 ins. The flowers should be gathered in bud and allowed to open indoors. There is an ivory white form which is scarcely so good as the lavender purple type. *Speciosa* is a dwarf late-flowering form with deep, richly coloured flowers.

All Apogon Irises should be moved in early autumn while the soil is still warm enough to encourage fresh root action, so that the plants become re-established before winter. They must not be allowed to become dry, and must therefore be watered in periods of drought.

Evansia Irises form a connecting link between the bearded and the beardless species, for the flowers bear a linear crest, something like a cockscomb. *I. cristata* (6 ins.), *gracilipes* (10 ins.), *lacustris* (4 ins.) are dwarf rockery species, which must have half-shade and soil rich in humus. They are easily managed if moved immediately the flowers have faded. Upheaval in autumn is nearly always fatal. *I. Tectorum* (18 ins.) and *Milesii* (30 ins.), the first dwarf and the second tall, have flat fringed flowers and are good border Irises, if frequently lifted and replanted. *I. japonica* (24 ins.), lilac, and *Wattii* (36–48 ins.), white, are species for the cool greenhouse, with branching sprays of delicate fringed flowers and evergreen foliage.

Propagation of Irises. — This is easily carried out either by dividing the rhizomes in the case of named varieties or by seeds in the case of the species. Seeds should be sown when ripe in pots of light soil enriched with leaf-mould, and the pots should then be plunged to the rim in the open ground. Seeds of species will then germinate in the spring, and the seedlings may be planted out in their permanent quarters as soon as they possess about four leaves. Seeds of hybrids germinate more irregularly and, if they are of any value, the ungerminated seeds should be sifted out and resown when the seedlings are put out. Seeds have been known to lie dormant in the soil for eighteen years and then to

germinate and produce healthy plants.—W. R. D.

NEW VARIETIES.

The following are some of the best :—

Iris Cantab.—This has fragrant light blue flowers, and an orange scarlet disc or ridge.

I. germanica Richard II.—This has white standards shaded lavender, and deep maroon falls lined with white.

I. Hoogiana.—This has two mauve flowers in each spathe, with a golden beard.

I. Iota.—This has pale mauve standards with darker falls.

I. Leucothœa.—This has purplish-lilac standards with a darker netting, and falls of the same colour but shaded grey, with black beard.

I. Little Bride.—This has erect pale lavender standards with paler falls, and an orange ridge down the middle.

I. Rotherside Masterpiece.—This has creamy-white standards with golden-orange falls.

I. sibirica Emperor.—This has larger and better flowers than the type, and grows 3½ ft. high.

I. s. Perry's Blue.—Both the standards and falls of this are dark blue, but the style is much paler.

I. Turkoman.—This has brown standards with blue veins. The falls are darker, and it has a deep blue beard. W. J. C.

IRISH GARDENING.

Gardening in Ireland, as in other countries, is largely controlled by climate and soil. Round the coast, especially in the South and West, the climate is comparatively mild, but against this there is the fact that in the extreme West strong winds from the Atlantic militate against satisfactory growth. On the other hand, even as far North as County Down, notably about Rostrevor, Castlewellan, and Newcastle, the climate is not unlike that of Fota in the extreme South, where, during the summer, the conditions are almost sub-tropical. In the vicinity of the Kenmare estuary and about Bantry the climate is milder than anywhere else in Ireland. In the midland counties, however, away from the influence of the sea, the climate is colder and more like that of many parts of Britain, but probably with a moister atmosphere. The soil, too, varies considerably, a great deal of it being calcareous. But in County Wicklow, where some of our most famous gardens are situated, there is little or no lime, and consequently Himalayan Rhododendrons and plants of the heath family generally flourish exceedingly well. This is true also of the milder parts of the North, and many similar plants grow there luxuriantly. It is noteworthy that at Howth, in County Dublin, Rhododendrons are a feature where sheltered from wind, the reason being the comparative mildness due to proximity to the sea, and the fact that the rock composing the hill of Howth is not of limestone; elsewhere in the county lime is present in quantity.

Thus it will be seen that no hard-and-fast rules can be laid down for gardening in Ireland, and the idea, common in Britain, that the climate is uniformly mild is quite erroneous. The mild districts alluded to are as a general rule so favourable to the growth of half-hardy plants that a large number are from time to time planted in the open. Many flourish for years, and astonish visitors, who are accustomed to see the same plants in greenhouses; yet the disastrous winter of 1916–17 killed more plants in Ireland than anywhere in the United Kingdom for that very reason.

During the summer of 1917 a fairly complete census was taken of plants killed and injured during the previous exceptional winter. From that it is possible to gain a fair idea of those which can be depended on for permanent effect.[1]

Trees and Shrubs.—Australia, Chile, the Himalayas, and Peru are some of the countries from which come many of the trees and shrubs characteristic of Irish gardens where the owners are enthusiastic.

Australian shrubs are represented by *Grevillea rosmarinifolia* and

[1] For lists see *Irish Gardening*, vol. xii. pp. 137, 138, 139, 140, 141, and 150.

Grevillea juniperina. The former is a handsome plant of dwarf spreading habit, leaves dark shining green, flowers red in clusters. The other is more erect, with narrow rigid leaves and yellow flowers. *Drimys aromatica* is an interesting plant also, suitable for the warmer districts. It forms a well-furnished bush with highly aromatic leaves.

From Chile we have the glorious *Embothrium coccineum*, which in some gardens is well over 30 ft. high, and bears masses of its beautiful scarlet flowers; *Eucryphia pinnatifolia*, a beautiful plant of the rose family with handsome white flowers, is evergreen, or nearly so, in mild localities, deciduous elsewhere; *Fuchsia macrostemma*, with attractive bright green leaves and long slender scarlet flowers, makes an attractive wall plant; while its varieties or hybrids corallina, globosa, gracilis, and Riccartoni are among the most delightful of autumn-flowering shrubs. *Fuchsia Riccartoni* will form large handsome bushes where allowed room to develop. *Abutilon vitifolium* is hardy in many places, and makes a wonderful display with its large pale purplish-blue or sometimes white flowers. *Tricuspidaria lanceolata*, from the Island of Chiloe, Valdivia, etc., is a glorious shrub in many Irish gardens, bearing abundance of its large pendent scarlet flowers in early summer; it is evergreen as a rule, but in cold districts may lose some of its dark green lance-shaped leaves. *Podocarpus nubigena* is rare, but should be noted as suitable for mild sheltered districts, as also is *Lomatia ferruginea*, a graceful shrub with fern-like leaves, green above, with a rusty tomentum on the under surface.

From the Himalayas we have such Rhododendrons as arboreum, barbatum, cinnabarinum, Falconeri, fulgens, glaucum, triflorum, and the more tender *R. grande* and *R. Edgeworthii*, which flourish in the mild non-calcareous districts. It should be noted by intending planters that the large number of new species recently introduced from China bid fair to become beautiful additions to our Irish gardens. *Abelia triflora* is also noteworthy, forming immense bushes bearing sweet-scented flowers; it was first introduced to the Botanic Gardens, Glasnevin.

From New Zealand come the Pittosporums, handsome evergreens with mostly inconspicuous flowers; they are, however, distinct shrubs with ornamental leaves, and make beautiful specimens. The hardiest species are Buchanani, crassifolium, Colensoi, Ralphii, tenuifolium, and the Chinese sort, daphniphylloides. *Pittosporum Tobira* from Japan has the most showy flowers, which are white and fragrant. Olearias also from New Zealand are successful, the best species being avicenniaefolia, macrodonta nummularifolia, oleifolia, and stellulata, the latter being an Australian shrub. *O. Haastii* is well known, and flowers freely in early autumn. Shrubby Veronicas do remarkably well in many places and are useful evergreens, many with beautiful flowers. The best sorts are Haastii, Lewisii, salicifolia, Traversii, sub-alpina, and rakaiensis among the larger growers, while dwarfer species include such as Armstrongii, Bidwillii, Canterburyensis, cupressoides decumbens, epacridea, Hectori, and pimeleoides. About Howth and Killiney, near Dublin, a dwarf blue Veronica allied to Autumn Glory has become naturalised on railway embankments, etc. It is very hardy, and flowers profusely in summer and autumn. The white-flowered *Leptospermum scoparium* makes huge specimens in some districts, and is probably the hardiest species; but Chapmannii, Nairnii, Nicholii, and pink and red flowered varieties, are beautiful in mild localities, and are worth trying wherever there is tolerable shelter.

A noble New Zealand plant is *Cordyline indivisa*, which flourishes in many parts of Ireland. The huge leaves reach a length of 6 ft. or more, and are 6 ins. wide in the middle; the veins are orange-coloured, and a large specimen is one of the finest sights to be seen in any Irish garden. *Plagianthus betulinus* and *Plagianthus Lyalli* are interesting New Zealanders, the former becoming a small tree in time with slender branches, clothed in summer with rounded lobed leaves; the flowers are unimportant. The latter, now often called *Gaya Lyalli*, is a handsome shrub, flourishing nearly everywhere as a wall plant, but in many places as a bush in the open. It bears in early summer quantities of pure white flowers. In some gardens plantations of New Zealand flax are a feature, but probably the handsomest variety is *Phormium tenax atropurpureum*, with dark purplish green

leaves, and in summer immense inflorescences of reddish-yellow flowers.

From Peru the two most notable shrubs in Irish gardens are *Desfontainea spinosa* and *Fabiana imbricata*, both handsome and attractive, the former with holly-like leaves and tubular reddish-yellow flowers, the latter with small heath-like leaves and white flowers. *Carpentaria californica* is a beautiful shrub, quite hardy, and most attractive when bearing its pure white flowers. Cold winds in winter and spring are its chief enemy, and a position should be chosen for it accordingly. Ceanothuses do well as a rule, though some suffered severely during the winter and spring of 1916–17. The evergreen section is susceptible to harsh spring winds, but when species such as *Ceanothus rigidus* and *Ceanothus papillosus* survived and continued to flourish in the vicinity of Dublin, it is obvious that the genus is suitable for planting in Ireland. The deciduous autumn-flowering kinds do well, and annually make a great show. Camellias are amongst the best evergreens for Irish gardens, and are ornamental at all times. *Camellia japonica* and its varieties, latifolia, Donckelaarii, etc., are far too seldom seen outside, considering their merits as flowering and foliage shrubs. *Camellia cuspidata*, with narrow long-pointed leaves, makes a neat and attractive bush, which bears pure white flowers.

Other shrubs and trees typical of Irish gardens are Coprosmas, *Fagus antarctica*, *Fagus betuloides*, *Fagus obliqua*, *Solanum crispum*, *Arbutus Menziesii*; and the common Strawberry Tree, *Arbutus Unedo*, *Fendlera rupicola*, Escallonias, the tree heaths (*Erica arborea*, *Erica lusitanica*, etc.), and Bamboos flourish in many places. Californian and Mexican Pines are good in many localities, and several species of Eucalyptus are generally hardy.

Herbaceous and Alpine Plants.—All the best plants of the herbaceous border and the rock garden do well in Ireland with reasonable treatment, and in the vicinity of Dublin and elsewhere there are numerous herbaceous borders of great beauty. Scattered over the country there are many rock gardens rivalling in extent and number of plants the best to be found in Britain. In the deep soil of County Meath, although the climate is cold, herbaceous plants do exceptionally well, and assume a colour more intense and pure than in many places.

It is difficult, however, to point to any herbaceous or Alpine plants peculiarly suited to Ireland as opposed to other parts of the kingdom. The majority of them grow vigorously when reasonably treated by skilled gardeners; but in some cases winter damp has a disastrous effect, especially on Alpines from high altitudes, many Androsaces, Saxifrages, and other plants with hairy leaves perishing in winter unless planted in crevices or on a sharp slope where they can be protected from overhead moisture.

Nevertheless, the moisture-loving species of Meconopsis, Primula, etc., do remarkably well, especially in the North, and should certainly be made a feature, since they are perfectly hardy as far as cold is concerned. In the comparatively cool climate of County Antrim magnificent groups and specimens are to be seen annually of such good plants as *Primula bulleyana*, as well as others, such as *P. Beesiana*, *P. Littoniana*, *P. pulverulenta*, *P. sikkimensis*, all of which attain larger dimensions than are usual elsewhere; and the same is true of *Meconopsis aculeata*, and other species of this plant, such as *M. integrifolia*, *M. Wallichii*, etc. It is noteworthy, too, that these and similar plants seed profusely in the same locality. Generally speaking, the North seems well suited to the growth of plants from high altitudes.

It is impossible within the limits of this article to mention a tithe of the plants successfully grown in Ireland, but any one beginning to furnish a garden will do well to commence with the hardier kinds first; then with experience of the soil and climate of the district it is very probable many more tender plants may subsequently be added. For fruit growing many of the limestone districts are equal to Kent, except for Pears.—J. W. B.

IRON AND IRON COMPOUNDS.

Gardeners with very few exceptions fail absolutely to realise the importance and the need of iron or iron compounds for plant-food. This failure of recognition is because iron is what is called a secondary fertiliser; in other words, it is not brought before gardeners nearly so much as are the usual fertilisers, nitrate of soda, sulphate of ammonia, superphosphate, and so on, which are in almost daily use during the summer months. But it has been neglected too long. Recent experiments have served to show that iron is a fertiliser of no small importance, and that while in large quantities it may prove detrimental or even poisonous to plant-life, in small quantities it produces remarkable results.

Research has shown that iron is the primary need of all green leaves of plants. If there is not enough iron in the soil the colour of the leaves will be pale, and that of the flowers will be poor in extreme, while in some cases it will be of an entirely different nature. This is shown by the effect iron has on Hydrangeas. It will turn a pink or white hydrangea into blue, and this fact is, of course, frequently taken advantage of, the plants being watered with a weak solution of some iron salt occasionally as the flowers open and so they become blue. When iron is given to any kind of flowers their colour is deepened, and it is probable that if we knew more about its use, we should be able to change the colour of many of our flowers to the type colours or something near them.

Experiments with Iron.—Instead of dealing with Iron Compounds under separate headings as we have done under Potash and Soda, we propose to speak about them collectively. But before proceeding to do this we want first to mention the enormous value of experiments with iron. Unfortunately up to the time this article was written but few experiments of any practical value have been made.[1] What is wanted is initiative in this direction, and initiative not only on the part of those in charge of Horticultural Colleges and Experimental Stations, but on the part of every man who calls himself a gardener. Such experiments should be commenced without delay, for they may take some years to complete, and efforts should be made to determine exactly the effects, good or bad, of various compounds of iron on the chief flowers and vegetables. There are some who may not like to take on this Herculean task; they may not have facilities for doing the large amount of accurate testing, and making the enormous number of observations necessary to complete the work. But if they cannot do it all, they can at least do a small part of it, such as, for instance, the taking of one compound of iron and the testing of its effects. Such results as are obtained ought to be communicated not to the Scientific Press, which no practical gardener ever reads, but to the popular gardening papers which are usually sharp enough to realise the value of any article showing original work, and will pay often generously for exclusive publication rights.

A point of importance when dealing with many iron salts is to keep them before use in tightly corked bottles or air-tight tins. Some of

[1] The experiments that have been made, such as they are, are of but little practical value, since they are never reported in language understood by gardeners who have not studied any Chemistry. The kind of information given may be useful enough to scientists, but it is Double Dutch to ordinary gardeners.—EDITOR.

them change very rapidly when exposed to the air, and lose much of their value, becoming in many instances very dangerous to plant life. As a general rule, soils of a very light almost white sandy colour, such as abound around Bournemouth, and, in fact, in many parts of the country where the tertiary sands prevail, need iron much more than strong dark soils, but there are some striking exceptions to this rule. Take, for instance, the strong Jurassic clays so abundant round Scarborough, or indeed so abundant right through the belt of Jurassic rocks which runs across England. These clays are often dark enough in colour, so is the soil, yet the bricks produced from them are yellow not red, a sure sign of the absence of iron. These soils need dressing with iron; if they were, the crops produced would probably be much better both as regards quantity and quality—for it has been shown that iron influences and increases quantity.

Some Iron Compounds.—If we treat iron compounds collectively instead of alphabetically, we may say that SULPHATE OF IRON (*Ferrous Sulphate*, $FeSO_4.H_2O$), or GREEN VITRIOL as it is called, is probably the most useful soluble salt. One ounce of this can be dissolved in 4 gallons of water, and the plants given a good soaking of this. It is useful for many crops and most flowers. In the winter, 1 oz. of this can be put on to each square yard and dug in. This chemical is an ingredient of very many lawn sands, as in large quantities it burns and completely kills weeds. Then there is iron itself. This is usually applied to the ground in the form of dust or filings, sometimes mixed with leather dust. Its use so far is in an experimental stage, as is also the use of iron oxide (*Ferric Oxide*, Fe_2O_3). As regards the latter, soils in iron-stone districts often contain more than enough of it, and sometimes such soils are poor in product as they are "too irony." Many things have been recommended as a dressing for such soils, the chief of which are gypsum and lime. Iron ammonia sulphate (or *Ferrous Ammonium Sulphate*, $Fe\,SO_4.(NH_4)_2SO_4.6H_2O$) can be used similarly to green vitriol or sulphate of iron. It is a much more stable chemical and does not spoil itself so readily.

Reference must also be made to other compounds of iron, namely, the phosphates, sulphides, chlorides, and nitrates of this metal. These chemicals, such as they are, may be said to be in an absolutely experimental stage up to the present, so there is plenty of work waiting for any one who cares to commence experiments with the compounds of iron.—E. T. E.

See also *CHEMISTRY FOR GARDENERS*.

IRON WEED.—See *VERNONIA*.

IRONWOOD (*Ostrya virginica*).—See *TREES*.

ISATIS (WOAD. Nat. Ord. Cruciferæ).—Only two species of this genus are really worth growing, and both are hardy biennials. These, *Isatis glauca* and *I. tinctoria* (the last is the well-known WOAD or DYER'S WOAD), both bear yellow flowers in July. The first grows only 2 ft. high, but the other often grows 1 yd. or more high. Both succeed in ordinary garden soil, and need very little care or attention, as they practically grow wild. Propagation by seeds sown in the usual way is not at all difficult, and planting may be successfully carried out from October to March.

ISNARDIA.—Now included in the genus *LUDWIGIA*.

ISOLEPSIS.—Now included in the genus *Scirpus*.

ISOSOMA. — See Cattleya Fly in *Insect Pests*.

ITALIAN GARDENING.

To those who admire the formal style, the Italian garden makes a strong appeal. In carrying out the scheme in the United Kingdom the designer is faced by certain difficulties. The southern climate of Italy makes it possible to grow many striking subjects which are too tender to flourish in our northern islands. Still, by a careful selection, it is possible to find many plants giving the needful beauty of form.

In the typical Italian garden much attention is paid to making the grounds harmonise with the house. Even when dealing with the smallest villa each feature of the garden is considered in its relation to the residence, and the views which are obtained from the windows. Formal beds of rigid geometric design predominate, and these are always filled with the most gorgeous flowers. Sculpture, balustrades, sundials, and stone seats are freely employed. No Italian garden is complete without a terrace; there is always a fountain too, and, quite likely, a cascade. Alleys of trees, preferably those with dark evergreen foliage, such as the cypress, are considered essential features. With such skill are the different parts of the garden arranged, that the formality never gives the impression of stiffness.

In many old English houses more or less successful attempts at this kind of gardening have been carried out. Those who wish to introduce the style into their own grounds would find it worth while paying a visit to any such garden that may be within reach. In this way it is easy to grasp the adaptations needful for carrying out the scheme in Britain. The geometric beds are usually bordered with box, and the intersecting paths are often paved. In the beds themselves a constant succession of the most brilliant flowering plants must be maintained from the spring to the fall. Compact bushes of bay and other evergreens, often in tubs, must in England take the place of the orange and lemon trees of Italy. Agaves in pots should be freely used in the summer, or, as permanent subjects, yuccas will be found to be of great value. The British gardener misses the lawn in the Italian design, but its absence is in keeping with the style. On the sun-baked hillsides of the southern peninsula the formation of a grass lawn is almost impossible. In more recent times a charming effect has been secured in the spring and early summer by the annual sowing of grass seed, intermixed with the seeds of poppies, cornflowers, and similar subjects. The gay colours of the flowers stand up in fine contrast to the bright green of the grass, and a most striking effect is secured.

Useful plants with striking foliage for the Italian garden include Acanthus, Aralia, hardy Bamboos, Cordyline, Gunnera, New Zealand Flax (*Phormium*), Tree Mallow (*Lavatera*), hardy Palm (*Chamaerops*), and Yuccas. Most of these subjects are fairly hardy in Britain. For the summer months more tender plants could be placed out of doors. The American Aloes (*Agave*), Bananas, Tree Ferns, and many of the Palms specially help in securing a striking Italian effect.

ITALIAN STARWORT (*Aster Amellus*).—See *Aster*.

ITEA.—For best species see *Shrubs*.

IVESIA.—Now included in the genus *Potentilla*.

IVIES.—See Hedera in *Climbing and Trailing Plants*.

IVORY DUST.—See "Hoof Parings" in our notes on organic products under Nitrogenous Manures in *Manures*.

IVORY MILK THISTLE (*Silybum eburneum*).—See *Silybum*.

IVY.—For best kinds see Hedera in *Climbing and Trailing Plants*.

IVY-LIKE MORNING GLORY (*Ipomoea hederacea*).—See CLIMBING AND TRAILING PLANTS.

IXIA LILY.—See *IXIOLIRION*.

IXIAS (Nat. Ord. Iridaceæ).

These are pretty, hardy bulbs, with brightly coloured, star-shaped blooms. They have narrow, Gladiolus-like leaves, and bear their flowers in spring on slender spikes about 12–15 ins. in height.

Culture. — Ixias like a warm, sunny border, with light, rich, sandy soil. They should be planted in September or October about 4 ins. deep. They make excellent pot plants. Five or six bulbs in a 4½-inch pot make a good display. They resent much heat, a winter temperature of from 40–50° F. being sufficient. The flowers are much brighter in colour when the plants are grown "cool."

Species and Varieties.—*Ixia azurea.*—Azure blue, with maroon centre.

I. Bridesmaid. — White flowers, with crimson eye.

I. Bucephalus. — A rosy-carmine variety, good in pots.

I. crateroides.—A brilliant cerise-scarlet variety, fine for cutting and for pot culture.

I. Emperor of China.—Yellow, with black eyes.

I. Excelsior.—A large-flowered variety, with crimson-scarlet blooms.

I. Linaresii. — Bright lilac-blue flowers.

I. Queen of Roses.—Rose.

I. Snowflake.—Pure white.

I. viridiflora.—This bears sea-green flowers, with a dark, almost black, centre; it is quite unique, and is splendid in pots.

I. White Swan. — White, with indigo eye.—J. J. & E. T. E.

IXIOLIRION (IXIA LILY. Nat. Ord. Amaryllidaceæ).—This is a small bulbous genus, allied to the *ALSTROEMERIA*, on which a separate article is given, and is included because its bluish-lilac flowers are so useful for vase decoration. In all but the colder parts of the British Isles it is hardy in light, well-drained soil, in warm, sunny positions.

Culture.—The bulbs should be planted in the autumn about 2 ins. deep, and protected with some light substance during the winter. This should be removed in February or early March, according to the season. When the foliage has died down, the bulbs should be lifted and stored until planting time. Ixiolirions may be grown in pots if they can be wintered in a frost-proof frame, and brought into a cool greenhouse about the middle of February.

Species and Varieties.—The best are:—

Ixiolirion Pallasii.—This bears pale lilac-blue flowers in umbels in early June. Height, 1–1½ ft.

I. tartaricum (more correctly *I. montanum tartaricum*).—This is similar to the above, but has smaller and more numerous flowers in the umbel. It flowers in the open in June, and grows 12–18 ins. in height.

JAPANESE GARDENING.

Interesting adaptations of the Japanese style of gardening are often to be seen nowadays. In the Land of the Rising Sun the laying out of a garden is controlled by certain fixed laws which are only partially understood by Westerners. Still, some delightful effects can be secured by following the leading rules on which the Japanese gardener works.

A Japanese garden makes a strong appeal to the amateur on account of the fact that it can be developed on a very small plot of ground. In planning, one of the most important points is to consider the effect of the garden as a whole. Every plant, and each piece of rockwork, must be thought of in its relation to the general scheme. All parts of the garden must be true to their particular characters. Any elevations, such as may exist or be built up, will be suggestive of mountainous country, and the plants must be in keeping with the idea. Dwarf or stunted trees and shrubs give a wind-swept appearance, and are well adapted to the hilly parts of the garden. Low, flat areas of ground give the impression of pasture, and should be planted with subjects having a free habit of growth.

No Japanese garden is complete without water. This may be in the form of quite a tiny pool, but if a stiff outline is avoided the pond will be one of the most attractive features. On the banks of the water moisture-loving plants can be allowed a freedom of growth that is natural in such situations. If possible the placing of a small island in the pool is to be recommended. Where the water can be narrowed down to give the effect of a stream, a bridge might be introduced. In situations where there is a natural supply of water more ambitious schemes may be attempted.

Native Japanese plants should predominate in the garden. Especially suitable are the spring flowering trees so widely used in the East, such as the almond, cherry, crab-apple, etc. These will usher in the spring with a wonderful wealth of blossom. Azaleas are useful for giving fine splashes of colour in the early summer, whilst wistaria should be freely used for training over pergolas. Japanese

Irises should of course be made a great feature of in the garden, and a selection of chrysanthemums will give a good effect in the fall. A useful small tree is the Japanese Maple, of which there are numerous varieties. Most of these provide splendid autumn tints just when there is a need of colour.

Other interesting plants which are very suitable for, if not inseparable from, Japanese gardens include *Anemone japonica, Forsythia suspensa,* Japanese Heaths, Japanese Lilies, Paeonies, *Physalis Alkekengi, Primula japonica,* and *Tricyrtis hirta.*

JAPANESE WINDFLOWER. — A name for *Anemone japonica.*

JAPANESE WISTARIA (*Wistaria japonica*).— See *CLIMBING AND TRAILING PLANTS.*

JAPANESE YEW.—A name applied to the genus CEPHALOTAXUS and to *Taxus cuspidata.* See *TREES.*

JASIONE (SHEEP'S SCABIOUS.[2] Nat. Ord. Campanulaceæ).—The comparatively unknown genus Jasione includes one hardy annual of fair merit for use in the rock garden. This (*Jasione montana*) is a pale blue, June flowering subject, growing about 8 ins. high. Sow seeds of it outdoors in March where the plants are to grow, and thin out, as soon as large enough, to 6 ins. apart each way.

Perennial Border Species.—These are suitable for the herbaceous border or rock garden. Provided they are not set in a fully exposed place, and are afforded some light, loamy soil they should do well. Propagation is best effected by seeds sown in the usual way or by the usual division of the roots in the spring. The three useful species are *Jasione foliosa, J. humilis,* and *J. perennis.* All bear blue flowers in June and July. The first and last are about 12 ins. high; *Jasione humilis* rarely exceeds 6 ins. however.

JASMINE PLANT.—A name applied to *BOUVARDIA,* which see.

JASMINUM.—For the best species see *CLIMBING AND TRAILING PLANTS.*

JEFFERSONIA (Nat. Ord. Berberidaceæ).—Only one species of this genus is commonly grown. This, *J. binata* (Syn. *J. diphylla*), is a little hardy herbaceous perennial suitable for edgings and margins to borders or for the rock garden. It bears white flowers in May, succeeds in light sandy soil in a sunny site, is propagated by seeds sown in the summer, or by division of the roots in the spring, and grows about 6 ins. high.

JERSEY ELM (*Ulmus campestris sarniensis*).—See *TREES.*

JERUSALEM ARTICHOKES. — See *ARTICHOKE.*

JERUSALEM CROSS (*Lychnis chalcedonica*).—See *LYCHNIS.*

JERUSALEM OAK (*Teucrium Botrys*). See *TEUCRIUM.*

JERUSALEM PINE (*Pinus halepensis*).—See *TREES.*

[1] The Kew Authorities refer it to *Tsuga Sieboldi.*—EDITOR.

[2] Or SHEEP'S-BIT SCABIOUS. — EDITOR.

JERUSALEM SAGE (*Phlomis fruticosa*).—See *PHLOMIS*. See also the genus PHLOMIS in *SHRUBS*.

JESSAMINE (*Jasminum officinale*).—See *CLIMBING AND TRAILING PLANTS*.

JESSAMINE POTATO TREE (*Solanum jasminoides*).—See *CLIMBING AND TRAILING PLANTS*.

JEW'S MALLOW.—The genus KERRIA. See *SHRUBS*.

JOB'S TEARS (*Coix Lacryma-Jobi*).—See *COIX* and *ORNAMENTAL GRASSES*.

JOBBING GARDENING: OPENINGS FOR WOMEN IN.—See *WOMEN GARDENERS*.

JONIRIS.—Now included in the genus *IRIS*.

JONQUILLA.—Now included in the genus *NARCISSUS*.

JONQUILS (*Narcissus Jonquilla*. Nat. Ord. Amaryllidaceæ).—These are not as much grown now as formerly, but are worthy of inclusion in the garden or greenhouse for the dual reason of the loveliness of their flowers and for the pleasantness of the scent they give.

Culture.—This is quite simple. Outside the bulbs should be planted about three times their own depth in soil, preferably in groups. They may be used for naturalising, and may be planted in the rock garden or rock border as well as in the flower borders. Indoors four should be set in each 5-inch pot, using light loamy soil, and giving plenty of water when the flowers open.

Varieties.—No special variety or varieties can be recommended here. The plants bear yellow flowers in the spring-time, and average 9 ins. in height.

[For the flower known as QUEEN ANNE'S DOUBLE JONQUIL and the SMALL JONQUIL see *Narcissus Odorus* in *NARCISSUS SPECIES*.—EDITOR.]

JUDAS TREE.—A name applied to the genus CERCIS, more especially to *C. Siliquastrum*. See *TREES*.

JUGLANS.—For the best species see *TREES*.

JULIDÆ.—See MILLEPEDES in *INSECT PESTS*.

JUNCUS (RUSH. Nat. Ord. Juncaceæ).—Most of the Rushes are too coarse for the water garden proper, but may be used for planting on stream or river sides, or, again, in the wetter and more marshy portions of the wild garden where they will thrive with very little attention. The genus is a large one, and as the plants are of but little value we do not propose to describe the species here, but merely to name the kinds most often grown. These are the TOAD RUSH (*J. bufonius*); the CANDLE RUSH (*J. effusus*, and its varieties *conglomeratus* and *spiralis*); the COMMON HARD RUSH (*J. glaucus*) used for basket making; and the MOSS RUSH (*J. squarrosus*).

JUNE BERRY or JUNE-BERRY.—A name applied to the genus AMELANCHIER, more especially to *A. canadensis*. See *SHRUBS*.

JUNE BUG and **JUNE BUG MAGGOT.** See under CHAFERS in *INSECT PESTS*.

JUNIPER.—See *MEDICINAL HERBS*, and see under JUNIPERUS in *TREES*.

JUNIPERUS.—For the best species see *TREES*. See also JUNIPER in *MEDICINAL HERBS*.

JUPITER'S DISTAFF (*Salvia glutinosa*).—See *SALVIA*.

KAFFIR LILY (*Schizostylis coccinea*. Nat. Ord. Iridaceæ).—This, also known as the CAFFRE LILY, CRIMSON FLAG, or WINTER GLADIOLUS, is a hardy rhizomatous-rooted plant introduced into British gardens in 1869. It has sword-like foliage, and bears on slender stems, averaging 1½–2½ ft. high, numerous bright crimson saucer-shaped flowers in October and early November. These spikes are excellent for cutting, the unopened buds expanding in water like those of the Gladiolus. It is hardy except in cold damp soils and exposed localities.

Culture.—To be seen at its best it should be grown in clumps in a warm, rich, well-drained soil; but not in one which is hot and dry, and a top-dressing of leaf-mould after the flowers are over will greatly benefit the plants. The bulbs may be planted any time between September and March.

The Kaffir Lily may be grown in pots in light rich soil. After potting in March, the pots are best plunged in the ground all summer and only brought into a greenhouse in late September or early October, when the flower spikes are appearing. Frequent watering is necessary, also repotting in March or April, when severe frosts have gone, after which the pots should be again plunged for the summer in the open ground.

KERRIA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

KIDNEY VETCH.—A name applied to *ANTHYLLIS*, which see.

KILLARNEY FERN (*Trichomanes radicans*).—See *FERNS AND FERN GARDENING*.

KINDS OF CROPS.

Every gardener is aware that there are four chief classes in the vegetable kingdom—flowers, fruit, fungi, and vegetables—but he is in most cases uncertain as to the precise meaning of such terms as Brassica Family, Bulbous Crops, Bush Fruits, Cabbage Tribe, Catch Crops, Culinary Crops, Gross-Feeding Crops, Hard Fruits, Headed Crops, Leaf Crops, Leguminous Crops, Onion Tribe, Rhizomatous Plants, Root Crops, Saladings, Seed Crops, Small Fruits, Soft Fruits, Surface Crops, Tap-Rooted Crops, Tuberous-Rooted Crops, Turnip-Rooted Crops, Umbelliferous Crops, etc. We thus propose to explain these terms in the present article:—

Brassica Family.—This includes all plants of the Cabbage Tribe, most turnip-rooted crops, and some others.

Bulbous Crops. — These have bulbous roots and are much like bulbs. Leeks, Spring Onions, Potato Onions, and Shallots are all of this kind. They must be distinguished from turnip-rooted crops, and this is easy, for a bulb is made up of scales which can be removed one by one, and this is not the case in a turnip-rooted crop.

Bush Fruits. — These include Black, Red, and White Currants, Gooseberrries, Loganberries, and Raspberries. Strawberries are sometimes included under the same heading. It may be applied to smaller bushes of Apples, Pears, and Plums as well.

Cabbage Tribe. — Strictly this consists only of plants of the Brassica Family, of which the leaves or heads are used as food. These include Borecole, Broccoli, Brussels Sprouts, Cabbage, Cauliflower, Chinese Cabbage, Chou de Burghley, Couve Tronchuda, Curled Greens, Kale, May Greens, Savoys, Winter Greens, etc.

Catch Crops.—These are used for growing between more permanent crops, or on ground not vacant for more than a month or two. They include Corn Salad, Endive, Lettuce, Radish, Spinach, etc. Mustard, Rye, Vetches, etc., are sometimes used as catch crops for digging-in purposes.

Culinary Crops.—By these is meant any crop which has to be cooked before use. Thus all the important vegetables are culinary crops, but saladings (eaten raw) are not.

Gross-Feeding Crops. — These are crops which like a lot of dung and thus need heavily manured land. The three most important are Cauliflowers, Celery, and Onions. Leeks are also gross feeders.

Hard Fruits.—Apples and Pears are the chief of these, but the term is applied to any fruits of which the flesh or peel is reasonably hard. Vegetable Marrows (if fruits at all) would be considered as hard fruits, and the same applies to Cucumbers, Melons, etc.

Headed Crops.—This term is by some confined to such crops as Borecole, Brussels Sprouts, Curled Greens, and Kale, which make a definite "head" at the top of the plant. Other gardeners, however, talk about heads of Asparagus, heads of Broccoli, Cabbage, Cauliflower, and Savoy, so the term is rather wide and vague.

Leaf Crops.—By these is meant any crop of whatever kind it may be that is used for its leaves. A few of the large number include Borecole, Brussels Sprouts, Cabbage, Chinese Cabbage, Corn Salad, Couve Tronchuda, Curled Greens, Endive, Kale, Lettuce, Nasturtiums, Savoy Cabbage, Seakale, Seakale Beet, Spinach, Spinach Beet, and Winter Greens.

Leguminous Crops.—All these belong to the Natural Order Leguminosæ, and have the power of utilising the nitrogen of the air to form nitrates. They include every sort of Bean and Pea that is grown in gardens.

Onion Tribe.—By this is meant all the crops belonging to the genus *Allium*. Chives, Garlic, Leeks, Onions, Potato Onions, and Shallots are the chief crops concerned.

Pea Tribe.—This term is loosely used to include all leguminous crops, but it should be abandoned.

Rhizomatous Plants.—By this is meant any crop possessing a swollen surface stem or root just under the soil. The best example is a flower—the Iris—used in medicine. Readers will be able to find other plants

coming under this category if they observe closely.

Root Crops.—This term is very comprehensive, including as it does all tap- and turnip-rooted crops. More often it is used for the former than the latter. Sometimes gardeners include in it bulbous crops, but this is quite inadmissible.

Saladings.—These are usually considered to include the smaller leaf and root crops which are eaten raw, such as Corn Salad, Endive, Lettuce, Nasturtium, Mustard and Cress, Purslane, Radish, etc. Cucumbers and Tomatoes, often forming an addition to the salad bowl, are not usually considered Saladings however.

Seed Crops.—In gardening, by this term we mean crops which are grown for their seeds which are eaten. These include Beans of all kinds; Indian Sugar Corn or Maize, and Peas of all kinds. The Marrow and Tomato are grown for their fruits and not for their seeds, and are thus excluded from Seed Crops.

Small Fruits.—This term often means the same as the term Bush Fruits, already explained. More often we mean small bushes of Apples, Apricots, Cherries, Peaches, Pears, and Plums, when we talk about Small Fruits.

Soft Fruits.—All fruits of which the flesh, skin, or peel is not hard is the best explanation of this term.

Surface Crops.—These are an opposite kind of crop to Root Crops; whereas the latter root downwards for some depth, Surface Crops root within a few inches of the surface and thus they need much more watering. The most important surface crops are the Saladings, of which we have already given a list.

Tap-Rooted Crops.—These have a long tap-root. At present all the turnip-rooted crops given in the next paragraph but one are included, but gardeners should distinguish the latter class as they need more surface cultivation than do the strictly tap-rooted crops, which are as follows: Beetroot (long), Carrots, Parsnips, Salsafy, and Scorzonera.

Tuberous-Rooted Crops. — Although botanists disagree, the following are considered tuberous-rooted crops by the gardener: Artichokes, Chinese Artichokes, Potatoes, and Potato Onions. Some flowers are also tuberous rooted, as, for instance, one section of the Begonia and all the Dahlias.

Turnip-Rooted Crops. — This term is comprehensive, including as it does all crops having any resemblance in the shape of their roots to a turnip. These include Beetroot, (Globe Beet), Cardoons, Celeriac, Kohl Rabi, Radishes, Swedes, Turnips, and Turnip-Rooted Parsnips. Many of these are of the Brassica Family, but by no means all.

Umbelliferous Crops. — These belong to the Natural Order Umbelliferæ (hence their name), which order contains many poisonous plants. The chief useful crops included in this term are Carrots, Celeriac, Celery, Chervil, Fennel, Parsley, Parsnips, and Skirret.

Care must be taken not to use terms with no meaning, such as the Potato Family, meaning that group of tuberous crops including the Potato, and so on.—E.

KINDS OF ROCKS.—See *Garden Geology.*

KINDS OF SCENERY.—See *Landscape Gardening.*

KING OF THE BLUEBOTTLES (*Centaurea depressa*).—See Cornflower.

KING OF MALE FERNS (*Nephrodium Filix-mas pseudo-mas cristatum*).—See *Ferns and Fern Gardening.*

KING-NUT (*Carya sulcata*).— See *TREES*.

KING'S GARLAND FLOWER (*Daphne blagayana*).—See *SHRUBS*.

KINGSACRE-BERRY.—See *BRAMBLES AND BERRIES*.

KINNIKINNIK (*Cornus Amomum*).—See *SHRUBS*.

KIRI (*Paulownia imperialis*). —See *TREES*.

KNAPWEED.—See *CENTAUREA*.

KNAUTIA.—Now included in the genus SCABIOSA. See *SCABIOUS*.

KNEIFFIA. — Now included in the genus ŒNOTHERA.

KNIPHOFIA (Syn. *Tritoma*. RED-HOT POKER, TORCH LILY, etc. Nat. Ord. Liliaceæ).—The Kniphofias are probably among the most brilliant of all hardy herbaceous perennials, and are of extraordinary value for all garden purposes. For making a splash of colour against the more sombre background of shrubs they are invaluable, but are too good as a rule for use in the wild garden. The smaller sorts prove striking features in the front portions of perennial borders, mixed borders, etc., while the taller species are grand for the back rows of the same borders.

Culture is not a matter of much difficulty. The plants succeed in ordinary light, rich, sandy soil in a sunny or lightly shaded site, and are propagated by division of the root-stock in the spring or by means of slipping off suckers from the root-stocks. In very exposed districts it is advisable to lift and winter in a frame, or to cover the roots with leaf-mould, cocoanut fibre refuse, etc., to keep them warm. Early and efficient staking is essential if the taller sorts are to be grown successfully.

What to Grow. — An enormous number of species and hybrids have been described. We recommend the following :—

Kniphofia aloides (RED-HOT POKER). — This is the well-known species, and a great favourite. It produces glorious flame-coloured flowers from June to October, on plants 3–8 ft. high. Among the best forms derived from this, flowering at the same time and of similar height, are : *Egypt* (sulphur-yellow) ; *Empress* (bright scarlet) ; *grandiflora* (brilliant flame and yellow) ; *Heroine* (yellow) ; *Ideal* (bright scarlet) ; *Leda* (orange-scarlet) ; *Maxima* (deep yellow) ; *Meteor* (rich dark yellow) ; *Nobilis* (rich orange) ; *Ophir* (orange-yellow) ; *Saundersi* (orange-scarlet) ; *Sirius* (bright reddish-orange) ; *Stella* (pale yellow) ; *Torchlight* (bright flame-colour) ; and *Triumph* (orange-yellow).

K. Burchellii.—This bears orange flowers in June, and grows 1½ ft. high.

K. foliosa.—This striking plant bears yellow flowers in August, but is not quite hardy. Its height is 3–4 ft.

K. Macowanii.—This also is not quite hardy, but is a splendid sort bearing richly red-tinted orange or flame-coloured flowers in August and September, on plants only 1½ ft. in height.

K. modesta.—This bears white flowers freely during the summer months, and averages 2 ft. in height.

K. Nelsoni.—This bears attractive bright orange or orange-vermilion flowers throughout the summer, and averages 2 ft. high.

K. Northiae.—This bears light yellow flowers, sometimes tinted red, from June onwards, and averages 5 ft. high.

K. Rooperi. — This sort bears bright orange or reddish-orange flowers in September, October, and November. It grows 3–4 ft. high.

K. sarmentosa.—This bears at-

tractive orange flowers throughout the summer, and grows only 2 ft. in height.

K. Tuckii.—This is often offered by nurserymen as being a brilliant orange-red. It is, however, a disappointing sort as its colour rapidly fades and leaves a poor pale yellow. The plant blooms from June onwards, and averages 2–3 ft. high.

K. Uvaria.—This popular sort of the trade is now considered synonymous with *K. aloides.*

KNIVES.—See *GARDEN TOOLS.*

KNOHL-KHOLL.—A synonym for *KOHL RABI,* which see.

KNOT GRASS or KNOTGRASS.—See *ILLECEBRUM, POLYGONUM, WATER GARDEN: PLANTS FOR THE,* and *WEEDS.*

KNOT ROOT.—See *INSECT PESTS.*

KOCHIA (Nat. Ord. Chenopodiaceæ).—*K. trichophylla* of the seedsmen (now referred by some authorities to the variety *trichophylla* of the weed *K. scoparia*) is an annual well worth growing, forming compact little plants which are striking if used as dot subjects in summer bedding. The foliage of the plant is not much to look at until late August or early in September, when it becomes a brilliant bright red. The flowers borne from July onwards are greenish and are produced on plants about 2 ft. in height. The best way is to raise and treat as a half-hardy annual, but it may also be grown in pots for greenhouse or conservatory decorations.

KOELERIA (Nat. Ord. Gramineæ). This is a genus of hardy grasses of which several species are grown at Kew. In dry districts the species prove useful lawn grasses, but otherwise must be considered as weeds of no garden value. The two best known species are probably *K. albescens* and *K. phleoides,* and its variety *grandiflora* (Syn. *K. berythea*), all of which are popularly known by the name of CRESTED HAIR GRASS.

KOELREUTERIA.—For the best species see *TREES.*

KOHL RABI (*Brassica oleracea Caulo-rapa.* Nat. Ord. Cruciferæ).—This vegetable, so long regarded only as food for sheep or cattle, is now an established favourite in many gardens, especially in those districts where it is well-nigh impossible to secure palatable roots of white or yellow turnips. In appearance the roots of these are totally unlike anything else we cultivate, having an almost bulbous stem, of a turnip character, with a top suggesting one of the more coarse kinds of winter greens. To be really palatable it is important that growth be made very rapidly and the roots eaten in a young or half-grown state. If left to attain full size, these become coarse and hard, invariably proving most disappointing to gardener and cook alike. A great advantage these possess over turnips is, the roots bear drought remarkably well.

Culture.—Seed for an early crop may be sown very thinly in April, subsequent small sowings being made until July to secure roots for early winter supply. When sown in their permanent positions, reduce the seedlings while still small to about 3–4 ins. apart. This allows each alternate root to be withdrawn when these reach a usable size. Seedlings bear transplanting very well in the driest weather, provided they are well watered immediately.

Kohl Rabi may be left in the open ground all winter or be stored in pits or a cold shed, but wherever

convenient the former is the better plan to adopt, ensuring plump roots of better quality.

Varieties.—The *Early Purple* and the *Early Green* are the best sorts to grow. The *Large Purple* and *Large Green* are usually too coarse.

F. R. C.

See also *ORNAMENTAL VEGETABLES.*

KONIGA.—Now included in the genus *ALYSSUM.*

KORO-MIKO (*Veronica parviflora*).—See *SHRUBS.*

KOROLKOWIA.—Now included in the genus FRITILLARIA. See *CROWN IMPERIAL* and *FRITILLARY.*

KORUMEEK (*Veronica salicifolia*).—See *SHRUBS.*

L

LABELS.—See article on *GARDEN LABELS.*

LABIA.—See EARWIGS in *INSECT PESTS.*

LABRADOR TEA.—The genus LEDUM and *L. latifolium.* See *SHRUBS.*

LABURNUM.—For the best species see *TREES.*

LACE BARK PINE (*Pinus bungeana*). See *TREES.*

LACEWING FLIES. — See *INSECT FRIENDS.*

LACHENALIA (Nat. Ord. Liliaceæ).

Greenhouse bulbs, 6–12 ins. high, succeeding in good loam, peat, rotted cow manure, and sand in equal parts. They are propagated from offsets and by seed.

Culture.—The bulbs should be potted early, not later than the middle of August, six or seven bulbs in a 5-inch pot. Do not press the soil too firmly, and let the tops of the bulbs be half an inch beneath the surface. Place the pots in a cold frame till about the middle of November, when they should be brought into the greenhouse or conservatory. The plants like plenty of air, but should not be placed within reach of a draught. The temperature should be maintained about 50° F. during winter. February is the season of bloom. The more pendulous varieties are useful for hanging-baskets.

Varieties. — Brightness, Cawston Gem, His Reverence, Nelsoni, Rose Barton, Rosemary, Ruth Lane, and the species *L. luteola maculata* are very good.—J. L. G.

LACKEY MOTH.—See *INSECT PESTS.*

LACQUER TREE (*Rhus vernicifera*). See *SHRUBS.*

LACTUCA (Nat. Ord. Compositæ).

The lettuce of our kitchen gardens and our salad bowls belongs to this genus and goes by one or other of the names *Lactuca sativa* and *L. Scariola.* The genus contains a few good border plants which are hardy perennials in habit, and are of importance where a representative collection is desired, otherwise they may be passed over. All those described below succeed in light rich garden soil in a sunny site, and can be propagated by division of the roots in the autumn or spring, at which times they may be successfully planted :—

Lactuca alpina (BLUE SOW-THISTLE).—This bears dark blue or purple-blue flowers from July onwards, and averages 1 yd. in height.

L. cretica.—This is a tall blue July blooming plant about 6 ft. high.

L. macrophylla.—This sort bears purple-pink flowers in July and August, on plants 3–4 ft. high.

L. Plumieiri.—This is a splendid sort bearing purple flowers from July to August, on plants 6 ft. high.

L. racemosa.—This is an attractive pale blue sort blooming from July to September, and growing 3–4 ft. high.

L. tuberosa. — This ornamental border plant is not included in the *Kew Hand-list,* but is well worth cultivating for its large blue flowers, which last are produced in September on plants 2 ft. high.

LAD'S LOVE.—See *ARTEMISIA.*

LADIES' BEDSTRAW (*Galium verum*). See *GALIUM.*

LADIES' FINGERS (*Anthyllis Vulneraria*).—See *ANTHYLLIS.*

LADIES' TRESSES (*Spiranthes autumnalis*). — See note at end of *HARDY ORCHIDS*.

LADY FERN (*Athyrium Filix-fœmina*). See *FERNS AND FERN GARDENING*.

LADY'S MANTLE.—See *ALCHEMILLA*.

LADY'S SLIPPER. — See *CYPRIPEDIUM*.

LADY'S SLIPPER ORCHIDS. — See CYPRIPEDIUM in *HARDY ORCHIDS*.

LADY'S SMOCK (*Cardamine pratensis*). See *CARDAMINE*.

LADYBIRDS.—See under BEETLES in *INSECT FRIENDS*.

LÆLIA.—See *ORCHIDS*.

LÆLIOCATTLEYA.—See *ORCHIDS*.

LAGURUS (Nat. Ord. Gramineæ). This is a genus of handsome ornamental grasses the best species of which, *L. ovatus*, popularly known as the HARE'S-TAIL GRASS, is described in our article on *ORNAMENTAL GRASSES*.

LAMARKIA (Nat. Ord. Gramineæ). This is a genus of hardy annual grasses. The best species, *L. aurea*, is referred to in our article on *ORNAMENTAL GRASSES*, which see.

LAMB'S LETTUCE.—See CORN SALAD in *SALAD PLANTS*, also *VALERIANELLA*.

LAMB'S-SKIN.—See *ARNICA*.

LAMBERT'S CYPRESS (*Cupressus macrocarpa*).—See *TREES*.

LAMIUM (DEAD NETTLE. Nat. Ord. Labiatæ).—This is a genus of nettle-like hardy herbaceous perennials, the leafage of which has no stinging properties. The species are of little garden value, though *L. maculatum* and its varieties *album*, *aureum*, and *rugosum* are sometimes grown in mixed or shrub borders. The type is purple; the varieties, however, bear white and reddish flowers respectively, the second having golden variegated foliage. All bloom from June to August, and average 12–18 ins. high. Another species of weedy appearance (*L. Galeobdolon*) is popularly known as the YELLOW ARCHANGEL, while a third (*L. purpureum*) is the troublesome RED DEAD NETTLE described in our article on *WEEDS*.

LAMPRONIA.—See RASPBERRY SHOOT BORER in *INSECT PESTS*.

LAND SCAB.—See COMMON SCAB in *POTATO DISEASES*.

LANDSCAPE GARDENING.

In Landscape Gardening one naturally seeks to attain "the beautiful," but it is not given to everyone to have the same tastes, or perception, as to the best means to attain it.

The senses by which we discover beauty are mostly sight and hearing, but in Landscape Gardening the latter is little exercised. With regard to the perception of beauty by the aid of sight, it is necessary to bear in mind that the whole matter is governed by lines, which may be either curved or straight, natural or artificial. The curved or serpentine line is indicative of grace. For instance, we say the country presents some graceful undulations; and again we say a winding stream through meadows with overhanging trees, is lovely. The same idea is also expressed in vegetation by the natural grace of the branches, the beauty of the flowers and foliage. Straight, angular, or broken lines, on the contrary, denote hardness and artificiality, though these may be entirely in keeping, when designed in connection with the architecture of the buildings, such as the terrace, the parterre, the Dutch garden, the avenue, the forecourt, etc.

The great principle underlying beauty in Landscape Gardening is unity, the harmony of all parts, the adaptation of the design of the garden in the immediate vicinity of the house to its architecture, passing gradually from that to the natural,

as the garden recedes from the house, until it merges into the scenery of the surrounding country. This, however, requires different treatment in accordance with our particular views of the character of the scenery, which may be divided into the following distinctive characteristics: (1) Grand; (2) Picturesque; (3) Wild; (4) Peaceful; and (5) Uninteresting. The characteristics are represented by :—

(*a*) Agricultural Scenery,
(*b*) Aquatic Scenery,
(*c*) Mountainous or Rocky Scenery,
(*d*) Pastoral Scenery,
(*e*) Seascape Scenery,
(*f*) Sylvan or Wooded Scenery,
(*g*) Urban Scenery,
(*h*) Wild Scenery.

In reproducing Nature in gardens, the idea governing this should be to borrow from her most agreeable scenes, improving that which is most beautiful by adding thereto harmony and variety in arrangement and colour, and concealing, or omitting, any imperfections. To attain this ideal there must be simplicity in design, gentleness in outline, easy undulations of the land, graceful winding walks, also a few appropriate ornaments in keeping with the architecture of the house. One also needs to give due consideration to the laws of light and shade in the planting of heavy or light foliaged trees and shrubs; to colour, in the judicious introduction of bright-coloured foliage plants, with those of more sombre character; to the combination of foliage for autumnal tints; to the harmony of new plantations with the general effect of the landscape; to comparative proportion of the several features or objects; as well as to the relative convenience of the different parts of the garden, and to the cost of maintenance, so that it shall not exceed the sum that the owner is disposed to pay.

Where the property is not situated in the town or suburb, it is important to hide the boundaries in such a manner that it is possible to obtain an uninterrupted view of the surrounding country. In open spaces this can be done by the use of a ha-ha, or a light iron post and wire fencing. Where there are already walls or close fences, these should be hidden by shrubs or ivy, so that their existence is not detected at a distance.

The judicious arrangement of the lawns contributes greatly to the beauty of the garden, especially if it is possible to embrace a view of the country beyond. They should be embellished with plantations or groups of trees, and a few isolated specimens placed in positions to bring nearer or to push back the perspective.

Water is always a source of pleasure, and gives life to the landscape. When it is running, it is often possible to vary it by widening or checking the stream in places, making it descend suddenly over a cascade or rapids broken by rocks placed loosely or arranged across the stream. In the case of still water, the natural position for it is at the bottom of a valley, or in the lowest part of the property. It should receive simple and natural treatment, a careful distribution of light and shade, and the arrangement of suitable trees and plants on the sides or margin.

The formal or geometrical style of Landscape Gardening has been handed down from remote times, when the few gardens then existing were small, enclosed with walls within the Monasteries, and were used principally for the cultivation of plants for food and medicine. At a later period there arose a desire

to have a pleasure garden in connection with the larger mansions that were then being erected; these were likewise treated in the formal style, with straight walks, plots of grass, severe parterres, clipped hedges, and avenues of trees.

Modern Landscape Gardening is in reality a composite or mixed style, being a judicious blending of the two former, and may be considered the intimate union of Art and Nature, of Architecture and Landscape.

To attain the best results in unity of design and harmony of the different parts, it is necessary to have a suitable knowledge of architecture, to understand the style of the garden which is to surround the house, to have the eye of an artist in designing the picture, and the knowledge of an engineer and gardener in carrying it out.—A. G. J.

LANDSCAPE STYLE.—See *GARDEN PLANS*.

LANTANA (Nat. Ord. Verbenaceæ). This is a genus of free-flowering, slightly scented, evergreen shrubs which are propagated by cuttings of half-ripened wood in the spring, in slight bottom heat. Pot in fibry loam, a little peat, and sand. Temperature required, 40–50° F.

Greenhouse Species and Varieties.—*Lantana delicatissima.*—Pale rose. Flowers from June to September. Height, 1–2 ft.

L. Drap d'Or.—Bright yellow. Flowers from June to September. Height, ½–1 ft.

L. lilacina.—Rose. Flowers from June to September. Height, 1–2 ft.

L. Magenta King.—Purple-scarlet. Flowers from June to September. Height, 1–2 ft.

L. Rayon de Soliel.—Deep yellow. Flowers from June to September. Height, 1–2 ft.

L. salviaefolia.—Red. Flowers from June to September. Height, 1–2 ft.

LAPAGERIA (Nat. Ord. Liliaceæ). This is a beautiful evergreen greenhouse creeper, with bell-shaped flowers hanging in clusters from the rafters of the greenhouse or conservatory. It is propagated by cuttings or layers in November in sandy peat. Pot or plant in good peat and sand, giving plenty of shade and moisture. Temperature needed, 40–45° F.

Greenhouse Species.—*Lapageria alba.*—Pure white. Flowers from October to December. Height, 2–15 ft.

L. rosea.—Deep rose. Flowers from October to December. Height, 2–15 ft.

L. superba.—Deep crimson. Flowers from October to December. Height, 2–15 ft.

NEW VARIETY.

Lapageria alba delicta.—This has large pale blush flowers, with pink veins.

LAPEYROUSIA (Nat. Ord. Iridaceæ).—Only one species of this genus is at all generally grown. This, *L. cruenta*, bears vivid red flowers spotted with black, from June onwards, and averages about 18 ins. high. It requires the usual treatment given to half-hardy bulbs, being potted in light soil in the autumn, and brought on in a greenhouse in the usual way.

LAPPA.—Now included in the genus *ARCTIUM*.

LARCH (*Larix europaea*).—See *TREES*.

LARCH APHIS.—See *INSECT PESTS*.

LARCH CANKER.—See *DISEASES OF PLANTS*.

LARCH ROOT ROT.—See CONIFER ROOT ROT in *DISEASES OF PLANTS*.

LARCH SAWFLY.—See *INSECT PESTS*.

LARGE CHAFER GRUB and **LARGE COCKCHAFER.**—See underCHAFERS in *INSECT PESTS.*

LARGE EARWIG.—See under EARWIGS in *INSECT PESTS.*

LARGE-FLOWERED EVERLASTING PEA (*Lathyrus grandiflorus*).—See *CLIMBING AND TRAILING PLANTS.*

LARGE-FLOWERED LILY TREE (*Magnolia grandiflora*).—See *CLIMBING AND TRAILING PLANTS.*

LARGE-FLOWERED WISTARIA (*Wistaria multijuga*).—See *CLIMBING AND TRAILING PLANTS.*

LARGE GARDEN SNAIL.—See under SLUGS AND SNAILS in *INSECT PESTS.*

LARGE TRUMPET FLOWER (*Tecoma grandiflora*).—See *CLIMBING AND TRAILING PLANTS.*

LARGE WHITE BUTTERFLY.—See under CABBAGE WHITE BUTTERFLIES in *INSECT PESTS.*

LARIX.—For best species see *TREES.*

LARKSPUR (*Delphinium.* Nat. Ord. Ranunculaceæ).—Many people do not know that the ever popular Larkspurs or Lark's Heels are close relatives of the stately perennial Delphiniums. The garden forms of the latter have been obtained chiefly from *Delphinium grandiflorum,* while the Larkspurs, as generally understood, have no doubt been evolved from *D. Ajacis* and *D. Consolida.* Larkspurs are elegant in foliage, stately in carriage, and effective in flower. The colour range found in the Rocket, Stock-flowered, and Emperor strains is fairly wide, from white, through shades of pink and rosy scarlet, to mauve and purple. The heights vary from 1 ft. in the dwarf forms, suitable for edging or massing, up to 3 ft. in the taller sorts, which are most valuable for grouping in large beds or borders. Plants raised in the autumn and winter in frames generally give the best results, but fine displays may be produced from a sowing in March. All Larkspurs pay for liberal treatment, and the taller kinds need the support of slender sticks. It may be added that practically all the Larkspurs make beautiful pot plants for conservatory decoration, and there are double as well as single-flowered varieties of most colours.

What to Grow.—Below we describe the best sorts:—

Delphinium Ajacis (Syns. *D. ambiguum* and *Consolida* of Sibthorpe).—This attractive, many-coloured, summer-flowering sort is a British plant and the forerunner of the Rocket group of Larkspurs. Its height is 1½ ft.

D. Consolida (Syns. *D. monophyllum, paniculatum, segetum,* and *versicolor*).—A blue sort with flowers in a loose spike which blooms in the early summer. From it the *Emperor* and other free-branching strains have been evolved. Its height is 1½ ft.

For herbaceous species, see article on *DELPHINIUM.*

LASER-WORT.—See *LASERPITIUM.*

LASERPITIUM (LASER-WORT. Nat. Ord. Umbelliferæ).—This is a genus of weedy, hardy herbaceous perennials. A large number of species have been described, none of which have much garden value. By some authorities the species are divided up amongst other genera, such as *Cachrys, Guidium, Ligusticum, Siler,* and *Thapsia.* Probably the best known species is *L. latifolium* (Syn. *L. glabrum*), popularly known as HERB FRANKINCENSE.

LASIAGROSTIS.—Now included in the genus *STIPA.*

LASTREA.—See NEPHRODIUM in *FERNS AND FERN GARDENING.*

LATANIA.—See under *Livistona chinensis* in *PALMS.*

LATE BLIGHT.—See *POTATO BLIGHT.*

LATE DESSERT PEARS.—See notes at end of *PEAR.*

LATE-FLOWERING CHRYSANTHEMUMS.—See *CHRYSANTHEMUMS: CULTIVATION OF.*

LATHYRUS (Nat. Ord. Leguminosæ).—This family, to which the Sweet Pea belongs and which now includes the genus *Orobus*, contains many annual species, some of which are climbers and some dwarf. Most of these are interesting, but they are not very effective for garden decoration. All the hardy annual species are quite easily raised from seeds sown in ordinary garden soil in autumn or spring, though slugs are very fond of the young seedlings.

Some of the best of the climbers are: *annuus* (yellow); *Nissolia* (crimson); *odoratus* (see article on *SWEET PEAS*); and *tingitanus*, the TANGIER PEA (purple-red).

A few of the dwarfer sorts that may be mentioned are: *angulatus* (red); *Cicera* (red); *sativus*, the CHICKLING VETCH (white); and *sphaericus* (crimson).

Perennial Border and Rock Garden Species.—The best of the Climbing Perennials are mentioned in our article *CLIMBING AND TRAILING PLANTS* (which see), so in the present paragraphs we confine our attention to some of the best herbaceous perennial species, all of which are exceedingly hardy and will thrive with little care in the commonest of garden soil, spreading more or less rapidly. They are extremely easy to propagate by division of the roots in the spring, and cuttings of young growth in the summer if pegged into light soil in a frame will root very freely.

Lathyrus albus. See *L. pannonicus.*

L. alpestris.—This is a pretty sort bearing purple flowers from midsummer to the end of July. It grows about 1½ ft. high.

L. canescens.—Syn. *L. filiformis*, which see.

L. cyaneus.—This bears attractive pink flowers, of which there is a blue form. Its flowering period is June and July, and its height about 12 ins.

L. filiformis (Syn. *L. canescens*).—This is a useful violet-purple, free summer blooming sort about 12 ins. high.

L. glaucifolius.—Syn. *L. ochroleucus*, which see.

L. hirsutus.—This bears red flowers from April to May, and grows about 1 ft. high.

L. luteus (Syn. *L. montanus*).—The two forms of this are both attractive plants. *L. luteus* itself is a deep orange-yellow, but its variety *aureus* is pale, almost lemon-yellow. Both are free summer blooming subjects growing about 1½ ft. in height.

L. niger.—This is an attractive purple sort blooming from June to July, and averaging 18–24 ins. high.

L. ochroleucus (Syn. *L. glaucifolius*).—This is a pale almost cream-yellow sort blooming from June onwards, and growing 18–24 ins. high.

L. pannonicus (Syn. *L. albus*).—This has many-coloured flowers, chiefly shades of red. It blooms from April to May, and grows 1–2 ft. high.

L. vernus (Syn. *Orobus vernus*).—This bears dark blue or purplish flowers from April onwards, on plants 12 ins. high. Useful varieties of it are: *albus* (white); *flaccidus* (pale purple); and *flore pleno* (double and palest rose).

LAUREL or SHINGLE OAK (*Quercus imbricaria*).—See *TREES.*

LAURUS.—For the best species see *SHRUBS.*

LAURUSTINUS (*Viburnum Tinus*).—See *SHRUBS.*

LAVANDULA (LAVENDER. Nat. Ord. Labiatæ).—This is a popular genus of sweet-smelling evergreen

and hardy herbaceous herbs. The COMMON LAVENDER (*L. spica*) is probably the best known, and both its varieties *alba* and *nana* should be grown. The FRENCH LAVENDER (*L. Stoechas*) is not referred to as a herbaceous plant by the Kew authorities. That known popularly as SWEET LAVENDER (*L. dentata*) is a very favourite species. The TRUE LAVENDER, botanically known as *L. vera* (Syns. *L. angustifolia, L. officinalis, L. pyrenaica,* and *L. vulgaris*) is classed at Kew both as a hardy herbaceous perennial and as a shrub. This, the most important species of all, is briefly dealt with under LAVENDER in our article on *POTHERBS*. Care should be taken not to confuse this genus with *Statice,* popularly known as *SEA LAVENDER,* under which last name a separate article appears, or with *Santolina,* popularly called COTTON LAVENDER, for which see article on *SANTOLINA.*

See also *SHRUBS*.

LAVATERA (MALLOW. Nat. Ord. Malvaceæ).—This is a genus of greenhouse shrubs, hardy annuals, biennials, and perennials. The first group is out of the scope of the present work, but we briefly describe the other sections below :—

Annual Species.—The only hardy sort is *L. trimestris,* a large bushy plant that may be raised from seeds sown in autumn or spring where the plant is to flower, as it resents transplantation. It bears charming silver-rose flowers in the summer and autumn, and grows about 2 ft. high.

The plants catalogued as *L. grandiflora, L. splendens,* and *L. s. rosea* are large-flowered strains of *L. trimestris* of high garden value.

Biennial Border Species. — These require the usual treatment for hardy biennials, and succeed in ordinary garden soil in a sunny position. Some of them are useful for cutting. The following species are recommended :—

Lavatera arborea (TREE MALLOW). This well-known plant is extremely useful for borders. It bears purple flowers in July, August, and September, and grows 6 ft. high. See also notes on *VARIEGATED TREE MALLOW.*

L. biennis.—This nurserymen's sort is grown at Kew under its proper name, *L. punctata.*

L. punctata.—This is a very attractive border plant, bearing bright reddish flowers in July and August on plants 4–5 ft. high.

Perennial Border Species.—These require the usual treatment for hardy perennials, and thrive in ordinary open soil in a sunny site. They may be propagated by seed or division of the roots in the usual way, and a successful time for planting is February or March. We recommend the following species :—

Lavatera Olbia.—This pretty sort bears red or rose-pink flowers in August, and grows about 1 yd. high.

L. salvitellensis is now considered synonymous with *L. thuringiaca* below.

L. thuringiaca.—This bears pretty pale blue flowers in August, and grows about 4 ft. high.

See also *SHRUBS* and *VARIEGATED TREE MALLOW.*

LAVENDER.—The genus LAVANDULA. See *SHRUBS*.

LAVENDER (*Lavandula vera*).—See *LAVANDULA* and *POTHERBS*.

LAVENDER COTTON.—See *SANTOLINA*.

LAVENDER GRASS (*Molinia caerulea*). See *MOLINIA*.

LAW : GARDENING AND HORTICULTURAL.—See *GARDENING LAW*.

LAW AS TO NUISANCES and **LAW AS TO TRAPS AND POISONS.**—See *GARDENING LAW*.

LAWN MOWERS. — See MOWING MACHINES in *GARDEN APPLIANCES*.

LAWN MOWINGS: THEIR USE IN THE GARDEN. — Few gardeners realise the enormous value of lawn mowings, or they would not burn them on the garden fire or allow them to rot with rubbish they intend burning, as they so often do.

For mulching purposes fresh or rotted lawn mowings are exceedingly valuable and should be largely used (see article on *MULCHING*). For digging in during the winter they form a valuable substitute for dung, especially if some bonemeal is added. Year-old lawn mowings are quite as mild as old hotbed manure, and may be used in the same way. Fresh lawn mowings may be used alone for the making of hotbeds where a sudden heat for a few days only is required. Mixed with a third of their bulk of fresh leaves a milder hotbed is the result, and mixed with fresh, strawy stable dung, a very economical hotbed is easily made. Mixed with vegetable refuse they induce it to rot more quickly, and an equal bulk of rotted lawn mowings and rotted weeds, etc., makes a useful manure for the bottom of celery trenches, especially if it is watered first of all with strong house slops. For digging into flower borders, lawn mowings about six months old prove invaluable where manure is scarce, and in the preparation of new borders, equal bulks of stable dung and month-old lawn mowings will be quite satisfactory. This does not exhaust the uses to which lawn mowings may be put, though it includes the chief.

Rotted Lawn Mowings.—Generally speaking, rotted lawn mowings are more generally useful than those which are fresh and green. There is, of course, a right way and a wrong one of making them rot, and as in most other cases the lazy way is the wrong one. The latter is the course usually adopted, and the mowings are allowed to fire their own heart out by being tipped carelessly down in a loose heap.

The best way of making them rot is to dig a large pit, similar to a manure pit, with a drain at the bottom as usual leading into a tub, so that nothing shall be wasted. Into this the mowings should be shot, and after they have been well trodden down a few buckets of strong slops, or water if slops are unavailable, should be emptied into them. The pit should be large enough to take the whole of the summer's supply of mowings, and the process of watering should be repeated after each weekly consignment of mowings has been emptied in. A full month should elapse after the last mowings have been added before the pit is touched. Then it should be dug out, using a fork or a sharp spade with a rounded blade to facilitate the work. The material should then all be mixed together and well broken up, some bonemeal being freely scattered over it meanwhile to improve it.

No time should be lost in using it after this, and the pit should not be disturbed sooner than necessary.

The strong smell of rotted or rotting lawn mowings makes it necessary that the heap or pit should be situated away from dwelling-houses, and work amongst it should only be done on a full stomach.—E.

See also *MULCHING*.

LAWN SAND.

While hand weeding is necessary to remove such deep-rooting weeds as dandelions and docks from lawns, there are many preparations which, if applied in the spring, will kill other weeds more or less effectually, and at the same time benefit the grass. These materials are known

collectively as LAWN SANDS, and individually by some distinctive or fanciful name. It is inadmissible here to praise any one make more than another.

Home-Made Lawn Sand.—Where the gardener has a taste for chemistry, he can easily make his own lawn sand, and make it at far less cost than would be incurred were he to buy the proprietary articles. First of all he should get about 4 st. of fine silver sand, sea sand, or other sand free from chemical impurities. He should then make a mixture of 4 lb. dry Nitrate of Soda and 4 lb. Sulphate of Ammonia, adding to this about 3 lb. of fine ground Sulphate of Iron. The mixture of the three chemicals should then be thoroughly mixed with the 4 st. of sand, adding a little at a time, and seeing that the chemicals are evenly mingled with the sand.

A cheaper lawn sand can be made by mixing together 1 lb. of Iron Sulphate and 3 lb. of Sulphate of Ammonia with 30 lb. of fine sand. This is specially suitable in districts where Nitrate of Soda is difficult to get.

Either lawn sand should be stored in tins or barrels till required for use, when it is scattered lightly over the turf in the usual way.

LAWN SWEEPERS.—See under MOWING MACHINES in *GARDEN APPLIANCES*.

LAWNS AND THEIR MANAGEMENT.—There is no better setting to the "stately homes of England," or the historic mansions which are scattered throughout the country, than a stretch of well-kept emerald turf. The magnificence of Westminster Abbey is intensified by the surrounding lawns in the same way that the grandeur of St Paul's is lessened by their absence. The "Gardens with their broad green walks where soft the footstep falls," were a striking feature of old times, and it is one of the most pleasing features of the modern landscape gardener's art that they are being freely introduced around our homesteads to-day.

The ideal lawn consists of a dense compact growth of the finest grasses. This can best be obtained by selecting varieties suitable for the locality, and giving them the cultivation necessary to produce the desired result. Nature has been very prodigal in giving us plenty of varieties of grasses to select from, and if we follow her lead we cannot do wrong.

Preparation of the Ground.—Turf of the best quality can only be produced on well-drained ground, and where necessary, draining should be done before anything else is attempted. There are very few soils which are not benefited by a judicious system of draining, and it is needless to expect to get a good lawn unless this is well done. The system of draining adopted should be such that the surface is quickly cleared of rain, and does not remain spongy for any length of time afterwards. When the drainage is completed, the ground should be either deeply dug or bastard trenched, taking care to retain the best soil on the top. Allow the ground to settle down before proceeding further with the work, because, however thoroughly it is rolled, the soil settlement is not so complete as is the case when the ground is allowed to solidify by the action of the elements. After the subsidence is complete, level the ground to the desired surface, and if the soil is of a rough or stony nature, it should be sifted to a depth of about 3 or 4 ins. These early cultural details exert a considerable influence on the future lawn.

Seeding and Turfing.—Seeding may be done either in spring or autumn. If the former period is decided upon, it is well to wait until all danger from frost is past, and yet sufficiently early to get the plants established before the summer drought commences. All things considered, April is generally the best month for sowing in spring. If autumn sowing is preferred, the earliest possible period after the last week in August, when rains have well moistened the ground, ought to be taken advantage of for doing so. If an analysis shows the soil to be deficient in any essential plant-food, it would be well to supply the deficiency before sowing the seed.

For lawns near the sea, *Festuca rubra* is one of the most useful grasses, while for city lawns the genus Poa is best. Taking lawns in general, a mixture of certain Agrostis, Cynosurus, Festucas of the ovina type, and *Poa trivialis*, answers well. The quantity of seed necessary to produce a good lawn varies from six to eight bushels per acre.

Where it is decided to use turf, the best way is to cut the turf into 1 ft. squares, and prepare these to an even thickness by laying them in shallow trays about 1½ ins. deep. These trays need to be made so that the turf can slide in and out, but otherwise to fit each square, so that there is no room for movement. Then with a sharp two-handled knife cut the underside to the gauged thickness. Treat the soil as advised for seeding, and get it rolled or trodden to an even, firm solidity. The turves can then be very quickly laid down, fitting them closely to each other, and the work when finished will present an accurate evenness that only requires intelligent cultivation.

Mowing.—Mowing should be started as early in the season as possible, and continuously followed up. It is a mistake to allow the grass to grow so long in spring that it has to be cut with a scythe before the lawn-mower can be used. A healthy well-nourished lawn cannot be mown too frequently while it is growing.

Rolling.—If a lawn has been well made there is not the need for the vigorous rolling to which it is frequently subjected. Many lawns are spoilt by rolling, especially if it is done in winter or when the ground is wet. If done at such times it causes a crust to form that renders it impossible for the finer grasses to exist, and creates conditions favourable for the growth of weeds. Rolling needs only to be done during the season of play on lawns used for sports, or to level the surface before mowing commences.

Renovating Old Lawns.—Most of the neglected old lawns can be got into a healthy condition by giving them suitable treatment. Impoverishment is generally the cause of their weedy, moss-grown condition. Winter is the best time to carry out the work of improvement, which consists of applying chemical preparations that will destroy the weeds, and at the same time nourish the grasses. When the weeds are removed, apply other nourishment to the grasses according to their requirements.

Shady Lawns.—These are improved by similar treatment to the above. *Poa nemoralis* is one of the best grasses to sow in the shade. Lawns can only be had in good condition by keeping them suitably nourished. As soon as mowing has ceased, apply chemical food in proportion to their needs. The neglect of doing so is the cause of many unsatisfactory lawns. A good

lawn is a pleasant return for careful treatment.—J. McD.

LEAD COMPOUNDS.

Metallic lead finds many useful applications in the garden. Lead strips are used on greenhouse roofs, lead pipes are used for conveying water, leaden tanks are used for holding water, and so on. Melted with an equal quantity of tin, lead forms SOLDER, and every gardener knows how useful this is for mending burst water-pipes, making old watercans hold water again, and for sealing up pots, cans, or glass jars containing sterilised fruit or vegetables. Attractive LEAD TREES for use in the formal or ornamental garden may be grown if a long rod of Zinc, or some similar metal, with one or two plain strips melted into it, is put for a time in a strong solution of say Lead Nitrate.

As the compounds of lead are all poisonous they are useless as fertilisers, and the use of most of them as insecticides or fungicides has not yet got beyond the experimental stage. Lead Acetate, the well-known SUGAR OF LEAD, as well as the phosphates and nitrate, have little horticultural value, though the first is used in the making of Lead Arsenate. This last is useful as a remedy for biting insects, and may be used with Bordeaux Mixture. Lead Carbonate and Lead Sulphate are ingredients of garden paints, the latter for those of inferior quality, while Lead Tetroxide (RED LEAD) is useful for rolling peas and beans in prior to sowing, to keep mice and birds off them.—E. T. E.

LEATHER-LEAF (*Cassandra calyculata*).—See *SHRUBS.*

LEAVES: Gathering, Storing, and Using.—Gardeners make a great mistake not to take advantage of the leaves which fall each autumn and use them as manure. Leaf-mould, or for that matter fresh fallen leaves, also form one of the most beneficial manures which can be applied to flower borders, the soil of which is heavy or medium; and if the fresh leaves be mixed with fresh cow or fresh pig manure, they form a highly desirable dressing for the vegetable garden, the soil of which is light. Rotted leaves, *i.e.* leaf-mould, is rich in that dark-coloured fat compound called humus. It is probably the richest in humus of all manures, but it is by no means the richest manure as far as plant-food is concerned. Leaf-mould properly made is peculiarly mild; it can be safely and advantageously applied to every kind of plant, including vegetables, known to the gardener; it can be applied to lawns, dug into every kind of border, used for protecting plants by heaping some of it over their crowns in the early winter, and it is an essential ingredient in almost every potting soil.

Considering the above points, it is advisable for gardeners to save as many leaves as they possibly can, for a cart full of leaves does not make very much leaf-mould. The first point which concerns us is:

Gathering Leaves.—Tidiness demands that the leaves shall not be long on the lawn or drives of the pleasure ground; but in the wild garden, and other places not in full view, the leaves can be left until all have fallen, to make one gathering up do. On the lawn and drives the best plan is to use a broom made of twiggy branches tied to a broom-stick. Long sweeps can be made with this, and the work done much quicker. It is advisable to choose as still a day for leaf sweeping as is possible, but if the leaves have to be gathered up on a windy day they should, of course, be swept in the same direction as the wind is blowing, otherwise much extra labour will be entailed. Hard drives can be swept easily and quickly with an ordinary garden broom. The leaves should be swept into heaps in spots out of the wind. In collecting leaves in the wild garden or the shrubbery the wooden rake is about the best tool to use. It should, if possible, be a wide one, though rather smaller than the average hay rake; then the work will be speedily done.

It must here be pointed out that some leaves do not make good leaf-mould. Such include among the shrubs—aucuba, laurel, and rhododendron. Among the trees, the leaves from walnut, ash, plane, sycamore, poplar, and horse chestnut are not good for making into leaf-mould, indeed the leaves from plane trees are absolutely worthless, and where these trees are abundant, it is advisable to collect them separately and destroy them by fire. The presence of a few shrub leaves amongst other kinds dropped into the shrubbery will not prove detrimental to the ultimate leaf-mould, but any great quantity will tend to make its value much less. As is well known, oak and beech leaves make the best leaf-mould, and if a sufficient supply of these leaves from the home garden cannot be had, the gardener should make arrangements with the keeper of the nearest wood in order to get some.

Having collected the leaves the next question is the

Storage.—This may be a simple or difficult matter. The usual way, unless there are special facilities,

is to dig a hole in the ground and shoot in all the leaves as collected, treading them well, and leave them for a year. However, very often this is not possible. In many gardens there is water very near the surface, and if a hole of the necessary size was dug, in a very short time it would be half-full of water. Although a certain amount of moisture is necessary for successfully changing leaves into leaf-mould, stagnant water will produce powerful vegetable acids which are highly detrimental to all plants. A kind of peat instead of leaf-mould is formed under such circumstances.

To avoid the possibility of "acid fermentation," as it is called, in districts where water is near the surface the leaves should be treated as follows: A square plot of ground in some spot away from trees is marked out with sticks, and round three sides of it a rough but thick wall of turf should be built. The leaves are then wheeled in, trodden down, and a few boards placed over them until they have all been collected. After this they are trodden down as firmly as possible, and either covered with a quantity of turf, or a good big load of manure stacked on to the top of them. This will compress them into very valuable leaf-mould.

Where there are special facilities, such as a corner between two buildings, the leaves can be stored there. It will not be necessary to cover them with manure or potting soil unless you wish for compressed leaf-mould, as they will not in such circumstances blow about.

Using Leaves and Leaf-mould.—We have described a few of their many uses at the beginning of this article, so need not repeat them. The gardener will find a large supply of leaf-mould quite indispensable.—E. T. E.

LEAVES OF PLANTS: Their Functions.—The term "leaf" covers a considerable variety of lateral appendages of the stem, which can be distinguished from branches by their form, position, and function. The leaf is usually flattened and bilateral. The typical green *foliage-leaf* consists of three parts. First, a basal portion, the *sheath*, which may or may not develop out-growths from its margins known as *stipules*, as in the Rose. The function of the sheath is the protection of the bud of the branch in its axil. The plane-tree affords an example of this, and the lime-tree shows how stipules are the protective agents. The middle part of the leaf is the *petiole*, which serves to project the leaf-blade into the air and light; it is usually, though not always, grooved along its upper side. The *leaf-blade* is the terminal portion of the whole; it is of very varied shapes, an enumeration of which occurs in any school botany book, as also are the numerous types of *hairs* clothing its surfaces, when these are not glabrous or smooth. The leaf-tip or apex also assumes very diverse forms, from the *truncate* tip of the tulip-tree leaf to the *acuminate* dripping-point of the sacred banyan.

The leaf-blade is traversed in most Dicotyledons by a midrib, having several main lateral veins from which a network of smaller ones ramify in all directions throughout the tissue. In most Monocotyledons a number of equal parallel veins, united by cross-connections, traverse the length of the blade. The function of the midrib and veins is to strengthen the blade against mechanical strains, to conduct water into all tissues, and to transfer the elaborated sap from the leaf into the stem.

The function of the leaf-blade is threefold:—

1. The manufacture by the chlorophyll or green colouring-matter contained in the corpuscles of the densely-packed cells of the darker green upper side, and more sparingly in the cells of the lower side, of carbohydrates, chiefly sugar and starch, by means of the carbon obtained from the carbon dioxide of the air, together with the hydrogen and oxygen obtained from the water conducted upwards from the soil. The sugar is passed down into the stem. Nitrogenous substances, consisting of the elements already mentioned, along with sulphur and nitrogen, are also manufactured in the leaf.

Light and an adequate *temperature* are necessary for the production of food-substances.

2. The *transpiration*, or giving-off, of the surplus water from the lower leaf-surface, a process helping to maintain the ascent of water through the plant. The tissue of the lower side of the leaf contains numerous air-spaces in which the water-vapour collects, until passing out through the *stomates* or pores which occur in great numbers among the surface-cells and often depressed below these. Stomates remain open or closed according to the amount of moisture in the atmosphere.

3. *Respiration*, or breathing, which the plant shares with the animal. This consists in the absorption of oxygen from the air and the expulsion of carbon dioxide, and occurs chiefly at night, but also (more slowly) in daylight, and always through the stomates.

Protection of the leaf against browsing animals, caterpillars, and slugs is afforded by hairiness, spininess (*e.g.* Gorse), or the possession of distasteful or injurious substances in the tissues, *e.g.* the needle-crystals of lime-oxalate in the cuckoo-pint (*Arum maculatum*) against slugs. A device to escape attacks from browsing animals is the arrangement of the leaves in a rosette pressed flat against the ground.

The leaves of plants growing in hot, dry climates are protected against excessive evaporation of water by (1) leathery texture due to thick epidermal cell-walls; (2) spiny consistence, involving great reduction of surface; (3) hairy or woolly covering of the surfaces; (4) waxy covering; (5) inrolling of the edges towards the lower transpiring surface, which is thus greatly sheltered; (6) turning of the edge towards the sun so that the rays do not fall full on the surface, as in *Eucalyptus*; (7) succulence, whereby the leaf becomes a reservoir of water, as in *Mesembryanthemum* and *Crassula*.

The leaf of many plants, *e.g. Monocotyledons*, is not differentiated, but has blade, petiole, and sheath merged into a simple lamina. The *scale*-leaf is devoid of chlorophyll and represents the leaf-base only; it occurs on underground shoots and on buds. The *cotyledons*, of which there are two, as a rule, in Dicotyledons and one in Monocotyledons, are usually very different in shape, and often in consistence, from foliage-leaves. Those which emerge from the seed above ground constitute the first one or two green leaves of the seedling. In other cases, *e.g.* the Oak, they are food-reservoirs, thick and fleshy, and remain below ground within the seed. In many Monocotyledons they act as suckers within the albumen of the seed, *e.g.* the Date Palm and the Onion; in the former, the cotyledonary stalk elongates and carries the embryo out; in the latter, it eventually appears above ground as a green leaf.

A *bract* is the green or coloured leaf which subtends an inflorescence or a single flower. *Bracteoles* are the (usually two) small leaves occurring alone on the flower-stalk. All the parts of the flower are modified foliage-leaves, having been evolved from them in the course of ages.

Very varied are the shapes and functions which leaves may assume. Some are modified for the purpose of catching insects, as those of the sundew (*Drosera*), Venus' fly-trap (*Dionaea*), and the remarkable pitcher-shaped terminal portion of the leaf in *Nepenthes*. In the side-saddle plant (*Sarracenia*) the entire leaf forms the pitcher. Many Bromeliads and the Teazel (*Dipsacus*) form water-tanks with their wide leaf-bases. The petioles of some (*Tropaeolum*) and the leaflets of others (Pea, Vetch) act as climbing organs in the form of tendrils. The Water Crowfoot has submerged leaves with linear or thread-like segments, while the floating leaves have a broad, slightly lobed blade.

LEEK SMUT.—See ONION SMUT in *ONION DISEASES*.

LEEKS (*Allium Porrum*. Nat. Ord. Liliaceæ). — Although in some quarters leeks enjoy their full share of popularity, others leave

much room for the wider recognition of these as one of the most wholesome and hardy of all winter vegetables. Failure to realise this is found chiefly among villagers and owners of small gardens, the majority of whom are under the impression that the cultivation of the crop entails considerable expense and much labour. Where extra large specimens are required for competitive purposes, the idea is not without some truth, but where supplies are wanted simply to meet the needs of the household, few crops are more easy to cultivate or so certain of giving good results.

Sowing.—Those who aim at large specimens should sow under glass early in January, putting three seeds in the centre of a thumb pot filled with a sandy compost. This is preferable to the more popular plan of sowing in pans or boxes, for where this last is done, a disturbance and breakage of roots can hardly be avoided prior to transplanting, which has to be done while the plants are still small and the roots very susceptible of injury.

Plants raised as above should be carefully hardened off by the occupation of a cold frame for about three weeks, the first fortnight in May being quite early enough to place them in their summer quarters.

For general use, an outdoor sowing made any time during March, or early April, may be expected to give satisfactory results.

A sturdy growth being at all times desirable, this should be borne in mind by the person sowing the seed. If a little finely sifted light sandy soil is scattered along the drills previous to sowing, the number of nice little roots each plant carries when transplanting becomes necessary, will be considerably greater than when the seed is sown in ordinary garden soil.

Planting Out.—For very large specimens it is usual to prepare a trench in a similar manner to that described in the article on *Celery*, the roots of these appreciating plenty of rich manure, that obtained from butchers' yards being excellent. We have also found the residue from cesspools and earth-closets, if buried sufficiently deep to ensure the roots being of considerable strength before reaching it, is the very finest aid to large growth, but for all ordinary purposes the grower may dispense with trenches, also extra heavy manuring; a dressing equal in bulk to that usually allowed for onions, or other crops, ensures splendid results if a foot is allowed each way between the plants.

Where the soil is in a highly fertile state, and the potato crop lifted early in June, strong Leek plants may occupy the same ground without further manure being added. If this is done, a foot between the rows and from 6–9 ins. between the plants will be ample.

When planting out, make a point of burying each plant as deep as the stem allows, leaving the lower leaves resting on the soil. Even where the soil is exceptionally fertile, or abundance of manure used previous to planting, this crop well repays a few thorough drenchings with liquid manure; and if these can be given during August and September, it will make an appreciable difference to the size of the Leeks.

Blanching may be done either by drawing the surrounding soil to the plants as growth proceeds, or by using brown paper, or collars made of zinc, sold by most seedsmen

for the purpose. These latter, although expensive, last many years, and ensure the quality of the produce being of the very highest order. All the necessary blanching should be finished by the end of November, after which the crop may be left to itself. See also article on *Vegetables: Blanching and Forcing.*

Varieties useful for any purpose include:—Ayton Castle Giant, Champion, Dickson's Exhibition, Dobbie's Model, London, Prize-winner, Royal Favourite, and The Lyon.—F. R. C.

For Method of Bottling see *Vegetable Bottling.*

LEERSIA (Nat. Ord. Gramineæ). This is a genus of moisture-loving grasses which are of botanical interest as hardy perennials, but of small garden value. They may, however, be grown at the water's edge in the water garden, or at the sides of a running rivulet. The best known species is *L. oryzoides*, the Rice Grass, which grows about 1 yd. in height.

LEGUMINOUS CROPS.—See *Kinds of Crops.*

LEIOPHYLLUM.—For the best species see *Shrubs.*

LEMNA.—See *Duckweed.*

LEMON-SCENTED VERBENA.—See *Aloysia.*

LENTEN ROSE (*Helleborus orientalis*). See *Helleborus.*

LENTILS.

It does not pay to grow these in this country, and land taken up by them had far better be cropped with something else, such as the Dutch Brown Bean. (See article on *Beans.*)

Lentils are imported so cheaply, and in such quantities, that the plant would have to be a very attractive one (which it is not) to be worthy of a place in English gardens to-day.

LEONOTICE (Lion's Turnip. Nat. Ord. Berberidaceæ).—This is an unimportant genus of hardy or nearly hardy perennials, tuberous or rhizomatous. The best known species is probably *L. Leontopetalum*, popularly known as Lion's Leaf, a yellow April blooming plant about 9 ins. high.

LEONOTIS.—Now included in the genus *Leonurus.*

LEONTODON.—See *Hawkbit.*

LEONTOPODIUM (Nat. Ord. Compositæ).—A genus of tufted plants with woolly white leaves. They will thrive in the rock garden on sunny ledges planted in calcareous soil, and are propagated by means of seeds sown in gentle heat in March. The favourite species is:—

Leontopodium alpinum (Edelweiss).—This has tufts of narrow leaves. Flowers white, in woolly heads, starlike in shape. Site, open. Flowering Period, June to August. Height, 6 ins.

LEONURUS (Lion's Ear, Lion's Tail, and Mother Wort. Nat. Ord. Labiatæ).—This is a genus of very free flowering autumn and winter shrubs and border plants, of which the first section can be plunged out of doors in ashes during August and September. Cuttings of the shrubs taken in the spring root freely under a hand-light or frame with little bottom heat. Young plants should be pinched back in their early stages to make good bushy, flowering plants by the autumn. The shrubs will succeed in light, sandy loam, with one-third fibrous peat. Temperature required, 40–50° F.

Greenhouse Species.—*Leonurus grandiflora* (Syn. *Leonotis Leonurus*, Lion's Ear and Lion's Tail).—Orange-scarlet. Flowers in October and November. Height, 1½–2½ ft.

L. ovata.—Orange. Flowers in August and September. Height, 1½–2 ft.

Perennial Border Species.—These require the usual treatment for hardy perennials, and succeed in common garden soil in a sunny site. They are best propagated by root division in the usual way in March, at which time they may be most successfully planted. As there are many better things they should only be grown in large collections. We recommend the following :—

Leonurus Cardiaca (Syn. *L. villosus*).—This is perhaps better known as the MOTHER WORT. There are various forms of it available, and it may be had in many colours, such as pure pink, rose-pink, pure rose, rosy-purple, purple-pink, pure purple, and pure red. It blooms from June onwards to October, and averages 2–4 ft. in height.

L. sibiricus.—This bears red flowers from July onwards, and averages 1–2 ft. in height.

LEOPARD'S BANE (*Doronicum austriacum* and *Senecio Doronicum*).—See *DORONICUM* and *SENECIO.*

LEPICYSTRIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING.*

LEPIDIUM (CRESS. Nat. Ord. Cruciferæ).—This is an unimportant genus of annuals and hardy perennials of little beauty. *L. Draba* is the WHITLOW CRESS ; and *L. latifolium* goes by the name of DITTANDER. The best known species of all is, however, *L. sativum*, the salad known as GARDEN CRESS or simply CRESS. A few remarks on the culture of this will be found under MUSTARD AND CRESS in our article on *SALAD PLANTS.* The name CRESS applied to this genus must not mislead beginners to think that it includes all kinds of Cress, as this is very far from being the case. For the popular and botanical names of some of the more important kinds of Cress see the separate short article on this plant.

LEPIDOSAPHAES. — See MUSSEL SCALE in *INSECT PESTS.*

LEPTANDRA.—Now included in the genus *VERONICA.*

LEPTASEA.—Now included in the genus *SAXIFRAGA.*

LEPTOGRAMME.—Now included in the genus GYMNOGRAMME, for which see *FERNS AND FERN GARDENING.*

LEPTOPTERIS.—Now included in the genus TODEA, for which see *FERNS AND FERN GARDENING.*

LEPTOSIPHON.—Now included in the genus *GILIA*, which see.

LEPTOSPERMUM (Nat. Ord. Myrtaceæ).—This is a genus of greenhouse evergreen shrubs from Australia, of easy culture, succeeding well in any ordinary greenhouse. Cuttings of young shoots are the best means of propagation. Set these firmly in May, in a mixture of peat and silver sand, placing under a bell-glass or hand-light with slight bottom heat and well shaded from the sun. Seeds may be sown in a warm house or hotbed in March. A suitable soil is two-thirds peat, one-third loam, and silver sand. Temperature required, 40–45° F.

Greenhouse Species. — *Leptospermum ambiguum* (Syn. *Kunzea corifolia*).—White. Flowers in June. Height, 4 ft.

L. flavescens.—White. Flowers in June. Height, 4–5 ft.

L. grandiflorum.—White. Flowers in June. Height, 6–8 ft.

L. multicaule.—White. Flowers in June. Height, 4–5 ft.

L. pendulum.—White. Flowers in July. Height, 4–5 ft.

L. scoparium.[1]—White. Flowers in June and July. Height, 2–6 ft.

NEW VARIETY.

Leptospermum Donard Beauty.—This has large red flowers edged with pink.

[1] Its leaves are used as tea.

LEPTOSYNE (Nat. Ord. Compositæ).—Several species of these Coreopsis-like plants are annuals, and most of them come from California. The only one of undoubted hardiness is *L. Stillmannii*, which, if sown in a sunny position in well-cultivated soil in April, will come into flower in about six weeks' time, producing its blooms on long stems. It produces large yellow flower-heads, which are grand for cutting, and grows 18 ins. high.

The only PERENNIAL BORDER SPECIES at all generally grown is *L. maritima*, a yellow summer and autumn flowering species about 1½ ft. high.

LEPTURUS (Nat. Ord. Gramineæ). This is an unimportant genus of grasses of no garden value. The best known species is *L. cylindricus*, the SEASIDE HARD GRASS, a plant so familiar to all of us that no description is necessary.

LESPEDEZA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

LESSER FLEA-BANE (*Pulicaria vulgaris*).—See *PULICARIA*.

LESSER PLANTAIN (*Plantago media*). See *PLANTAGO*.

LESSER SPEARWORT (*Ranunculus Flammula*).—See note at end of *RANUNCULUS*.

LETTUCE (*Lactuca sativa*. Nat. Ord. Compositæ).—A good crisp lettuce any time from early in May until the close of summer rarely fails to meet with general acceptance, and although in the most favourable seasons it must be allowed that quite good results often follow indifferent or lazy cultivation, where the soil is poor and the summer hot and dry, not only will the lettuces grown under such conditions be small and of very inferior quality, but there is great risk of losing the whole crop owing to premature running to seed. Soils, seasons, and variety sown count for so much with this crop that, where lettuces are highly prized, the importance of always ensuring the conditions under which the crop is to be grown to be as near ideal as possible, should be fully recognised. These three conditions may be summed up as follows: A deep and heavily manured ground, plenty of room for the proper development of every leaf the plant produces, and abundance of moisture at the root throughout all stages of growth. Where this is assured there need be little fear of anything but satisfaction following a sowing made at any time.

Sowing.—To get fully grown lettuce early in May, a pinch of seed should be sown in a warm greenhouse early in February, always providing a well-drained pan and using a light porous soil. The seed, which invariably germinates exceptionally well, should be sown very thinly, covered with a very light sprinkling of soil, and after the little plants appear, water must be given with more than ordinary care, or many will damp off before attaining a size large enough for transplanting. The seedlings from this sowing may be transplanted into other boxes as soon as each has made two true leaves, and if carefully nursed along in the house, and gradually hardened off by placing for a week or fortnight in a cold frame, they should be ready to occupy a sunny border at the end of March.

Good lettuces from June onwards are usually ensured by making an outdoor sowing in a warm spot early in March; successive small sowings every fortnight until the end of August should carry on the supply until winter sets in.

Transplanting should always be done while the plants are quite small, for the twofold reason that they suffer but little check, and plants allowed to remain in the seed-bed until they get large take a long time to get their roots well established in new soil, invariably proving disappointing even if constantly watered.

Where space permits, instead of sowing in the ordinary seed-bed, better and more rapid results will follow if seed is sown in the open garden where the crop is to mature, no transplanting to be attempted. If this is decided upon, the seed should be sown very thinly indeed, and whenever possible protection afforded against birds, which soon play havoc with the seedlings when they appear. When well through the soil reduce the number of plants, leaving them 3 ins. apart, and later 6 ins. When these latter nearly touch, pull out each alternate plant, at which stage they make a most excellent salad.

Overcrowding being one of the most fruitful causes of "bolting," this should be guarded against. It is safe to plant at 6 ins. apart, pulling up each alternate plant when about half grown. From this stage onward, plenty of moisture will be needed, and feeding will much improve both growth and quality.

Winter Lettuce.—Good lettuce may be had all the winter by those possessing garden frames. The seed should be sown early in September, and after placing a good bed of rich soil in the frame, fill it with the strongest of these plants as early in October as possible, giving plenty of fresh air in favourable weather.

On light soils, seeds of one of the more hardy varieties may be sown in August, and planted out in the open garden. These often pass the winter unharmed, but the quality is rarely as good as others more quickly produced, and for this reason large sowings are not advised.

Varieties. — *Cabbage Sorts.* — Sutton's Ideal, Lord Kitchener, Favourite, Early Market, May King, Wonderful, Defiance, Reliance, All the Year Round, Stanstead Park, MacHattie's Giant, the last three being suitable for autumn sowing and winter use.

Select Cos Sorts.—Jumbo, Kingsholm, Crystal Cos, Vaux's Self-Folding, Exhibition, Bath Black Seeded, Dunnett's Bath, Hick's Hardy, the last three for autumn sowing and wintering out of doors.

F. R. C.

[Other Salad Plants are dealt with in our article of that title.—EDITOR.]

LETTUCE ROOT APHIS.—See *INSECT PESTS.*

LEUCANTHEMUM.—Now included in the genus *CHRYSANTHEMUM.*

LEUCOCYCLUS.—Now included in the genus *ANACYCLUS.*

LEUCOJUM.—See *SNOWFLAKE.*

LEUCOPLASTS. — These are starch grains. See FOOD STORAGE AND DIGESTION in *PLANT PHYSIOLOGY.*

LEUCOSTEGIA.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING.*

LEUCOTHOE.—For the best species see *SHRUBS.*

LEVELLING.

Large areas, such as land for tennis courts, will prove too difficult for the gardener to level successfully, and the work should be entrusted to experts who are doing this kind of thing every day. Smaller areas can be done with the aid of a spirit-level. Levelling is an operation which requires much patience on the part of the inexperienced gardener. As it is very expensive on a large scale, none but

very serious consideration should be given to such work before starting.

LEVISTICUM (LOVAGE. Nat. Ord. Umbelliferæ).—One species of this genus, *L. officinale*, and its variety *variegatum*, both popularly known as LOVAGE, are sometimes grown in the borders, and are hardy herbaceous perennials of the easiest culture. The genus was once united with *LIGUSTICUM*, upon which we devote a separate short article. The English name of both genera is LOVAGE, and it seems a pity to keep distinct, plants which are so greatly similar as these.

LEWISIA (BITTER-ROOT, SPATLUM. Nat. Ord. Portulaceæ).—This is a genus of Californian plants with succulent leaves and richly coloured flowers. All are suitable for the rock garden, and should be planted in a dry position in full sun. It is essential that they are kept dry after growth is finished and during the winter. They are easily propagated by means of seeds sown in spring in a little heat. We recommend the following five species :—

Lewisia Cotyledon.—This has rosettes of fleshy leaves. Flowers pink, striped with buff or white. Site sunny. Soil rocky. Flowering Period, May to June. Height, 4 ins.

L. Howellii.—This is similar to the above, but with narrower leaves having crisped margins. Flowers pink, but striped with white. Site very sunny. Soil rocky. Flowering Period, May to June. Height, 4–6 ins.

L. Leana.—This has tufts of narrow, fleshy leaves. Flowers small and pink, striped with white. Site sunny. Soil rocky. Flowering Period, June. Height, 2–4 ins.

L. rediviva.—This has rosettes of narrow green leaves. Flowers large and bright satiny rose. Site very sunny. Soil rocky. Flowering Period, June to July. Height, 4 ins.

L. Tweedyi.—This has rosettes of broad, fleshy leaves. Flowers bright pink and large. Site sunny. Soil rocky. Flowering Period, August. Height, 4 ins.

LEYCESTERIA.—For the best species see *SHRUBS*.

LIATRIS (BUTTON SNAKE-ROOT. Nat. Ord. Compositæ).—Several species of *SERRATULA* are now considered species of this genus, which contains a number of very beautiful herbaceous perennials which are nearly hardy. They are useful alike for the perennial border or the sunnier and warmer parts of the mixed border, but in cold, exposed districts do not stand the winter very well, and are best lifted in late October. The little balls of soil round the roots are then sunk in coke dust in a frame till March, when as a rule they may be safely replanted in the open ground. As regards soil they are not very particular, but appreciate a light medium containing some peat, and are not fond of lime. Propagation is best effected by division of the roots in the spring, and though autumn planting is highly successful in such warm counties as Cornwall, March planting will be more satisfactory elsewhere. We recommend the following species :—

Liatris acidota (Syn. *L. mucronata*).—This is a purple August flowering sort, growing about 4 ft. high.

L. elegans (BLAZING STAR).—This is probably the most favourite sort of all, with its bright purple flowers in September. It grows about 4 ft. high.

L. graminiflora.—This is a most attractive pink August blooming sort, about 1 yd. high.

L. mucronata.—Syn. *L. acidota* above.

L. punctata.—This bears purple flowers in August, and grows 3–4 ft. high.

L. pycnostachya (KANSAS GAY FEATHER).—This attractive sort bears rich purple flowers from August to September, and grows 3–4 ft. high.

L. scariosa (Syn. *Serratula scariosa*).—This bears purple flowers in July and August, and grows about 1 yd. high.

L. spicata (Syn. *Serratula spicata*).—This is a very attractive sort, bearing tall spikes of purple flowers in September, and growing nearly 2 yds. in height.

L. tenuifolia.—This bears purple flowers in September and October, but rarely exceeds 2 ft. in height.

LIBANOTIS.—Now included in the genus *SESELI.*

LIBERTIA (Nat. Ord. Iridaceæ).

This is a genus of herbaceous perennials not very hardy in the colder districts, and thus benefiting by being wintered in a frame or cold greenhouse. They prefer a mixture of good peat and maiden loam, while the best way to propagate is by root division in the spring. We recommend the following: *L. formosa* (Syn. *L. ixioides* of some authorities); *L. grandiflora* (the best species); *L. ixioides* (classed at Kew as a distinct species); and *L. pulchella* (Syn. *L. Laurencii*). All bear white flowers from early April to the end of May, and average about 1½ ft. in height.

LIBERTY CAP.—See HARMFUL FUNGI in *FUNGI: EDIBLE AND HARMFUL.*

LIBOCEDRUS.—For the best species see *TREES.*

LIFE HISTORY OF FLOWERING PLANTS.—See *PLANT PHYSIOLOGY.*

LIGHT AND GERMINATION.—See *GERMINATION OF SEEDS.*

LIGHT SOILS: ARTIFICIALS FOR.—See *ARTIFICIAL FERTILISERS.*

LIGHT SOILS: VEGETABLES FOR — See *VEGETABLES: GENERAL CONSIDERATIONS.*

LIGHTNING GARDENING.

Nowadays the gardener, like most other folk, is often anxious to get quick results. In this connection a curious plan known as lightning gardening is of interest. By this means the seeds of some of the salad plants, such as mustard and cress, lettuce, etc., may be induced to germinate in an hour or so, and even show a certain amount of leaf development. As a first step the seeds must be soaked in water[1] for at least twenty-four hours. Then prepare a mixture as follows; Get a bucketful of fine light soil and a lump of fresh quicklime about the size of one's fist. Put the lime on some flat surface and grind it to a powder, taking care to keep it quite dry. Then thoroughly mix the lime with the soil, which should be rather dry.

Place the soil and lime in boxes or pans to the depth of about 3 ins. Taking the seeds that have been soaking, scatter them somewhat thickly on the soil. Cover with a very thin layer of more soil, water through a fine rose, and finally cover the boxes with sheets of glass. The action of the water on the lime causes this to heat, and the high temperature of the soil brings about an astonishingly rapid germination of the seeds. In a very short time these burst through their cases and the small plants appear. The growth continues until the seedling leaves have developed.

A somewhat similar idea is that which French growers occasionally

[1] Alcohol has been used in some experiments, but its use is not to be recommended as it does not produce reliable results.

adopt to secure the rapid opening of roses. In this case a bush is selected in which the buds are in an advanced state but not expanded. A trench is opened up about 6 ins. deep around the bush, and into this is scattered a few handfuls of powdered alum. The soil is then filled in. The bush is covered with matting, or similar material, arranged on a wooden framework. Water is poured on to the ground where the trench was dug out and the action on the alum generates heat accompanied by volumes of steam. In the course of an hour or so the rosebuds expand into perfect flowers.—S. L. B.

LIGULARIA.—Now included in the genus *SENECIO*.

LIGUSTICUM (LOVAGE. Nat. Ord. Umbelliferæ).—As already remarked in our article on *LEVISTICUM*, this last-named genus was once united with the one now under notice, but at the present time is considered distinct from it. Both have the same English name, both are hardy herbaceous perennials, and both are similar in action. As a medicinal plant Lovage has, however, declined; it was once used for a large variety of purposes and obtained considerable popularity as a diuretic. Now, however, PARSLEY PIERT (see article on *MEDICINAL HERBS*) seems to have superseded it. A number of species are grown, such as *L. actaeifolium*, *L. mucronatum*, *L. pyrenaicum*, and *L. Thomsoni*. The most popular species is probably *L. scoticum*, the SCOTCH LOVAGE, a pink summer blooming plant about 1 yd. high, of which a white form is also available.

LIGUSTRUM.—For the best species see *SHRUBS*.

LILAC.—A name applied to the genus SYRINGA, which see in *SHRUBS*.

LILIES (Nat. Ord. Liliaceæ).

The family of the Lily is a large one. About fifty species are under cultivation, in addition to a number of Hybrid Seedlings. They can be divided into six distinct sections:—

1. CARDIOCRINUM includes varieties such as *Lilium cordifolium* and *Lilium giganteum*, with large funnel-shaped flowers on tall stems with heart-shaped leaves.

2. EULIRION includes *Lilium candidum*, *Lilium japonicum*, *Lilium longiflorum*, *Lilium Parryi*, *Lilium Wallichianum*, large flowered, trumpet shaped, and mostly light coloured.

3. ARCHELIRION includes *Lilium auratum*, *Lilium speciosum*, *Lilium tigrinum*, etc. etc., mostly large spreading flowers, very attractive in colour.

4. ISOLIRION includes *Lilium concolor*, *Lilium croceum*, *Lilium dauricum*, etc. etc., very hardy, generally early flowering, and mostly erect in flower and cup-shaped.

5. MARTAGON includes all the most common garden Lilies of the Turk's Cap Tribe, such as *Lilium chalcedonicum*, *Lilium Martagon*, *Lilium monadelphum*, *Lilium pardalinum*, *Lilium polyphyllum*, *Lilium superbum*, *Lilium testaceum*, etc., reflexed petals and very showy.

6. NOTHOLIRION includes *Lilium Hookeri* and *Lilium roseum*, quite distinct from other species.

Culture.—As regards cultivation, there is no great difficulty. Lilies can be grown in any ordinary garden, but most of the varieties like peat, and this should be applied at the time of planting, when the soil should also be enriched with manure. Some varieties like a little shade, but should not be overhung by large trees. Lily

bulbs should not be left out of the ground or uncovered for any length of time, and, when planted, they should remain in the same position for as long as possible, as they resent being disturbed. Great care should be taken not to plant the bulbs too deeply, and when once they are established, a good mulching with well-decayed manure will be of great assistance to the plants. Sheltered positions must be found when planting, as the larger number of the varieties of the Lilies grow erect and are easily blown down by the wind.

There are several methods of propagation, and plants can easily be raised from seed by bulblets which form in the axils of the leaves on some varieties, and also from the scales of the bulbs when pulled apart. Light soil should be used for this purpose and the scales inserted round the edge of a pot, when they will soon form little bulbs.

The whole of the Lily family is very decorative for borders, and some of the flowers are highly scented, making them additionally attractive.

Growing Indoors.—Some varieties are used for growing in conservatories or cool greenhouses, where they can easily be cultivated, and by using retarded bulbs, which can be obtained from seedsmen, the period of flowering can greatly be extended.

One of the best species for pot culture is *Lilium auratum*, and very large trusses of flowers can be obtained from one bulb. Other good sorts for growing inside are *Lilium giganteum*, *Lilium Harrisii*, *Lilium longiflorum*, *Lilium speciosum roseum*, etc. etc.

When growing Lilies in pots the bulbs should be placed in half-filled pots, which should be well drained, and a little peat should be incorporated in the soil. To prevent fungus, which often appears in imported bulbs, a little powdered charcoal should be spread on the bulb.

When the growth commences, moisture should be given, and an occasional syringing. As soon as good root action is obtained, and a growth appears in the centre, more soil can be added to the pots, and when the flowers are formed and begin to develop, a little liquid manure should be applied, but used very sparingly.

Some of the varieties are only half-hardy, and when grown in borders, attention should be given in the winter and the roots covered with litter or ashes, which should be removed again before growth commences in the spring.

The period of flowering extends from the early summer to well on into the autumn.

Much has been done of late years in the way of hybridising, and some very useful garden varieties will appear when flowering bulbs can be put on the market.

Sorts to Grow.—To include and describe all the varieties now in commerce would form a rather formidable list, but I give below a short description of some of the better known and popular sorts :—

Lilium auratum.—A good old Lily from Japan which needs no description as it is well known to all garden lovers. Colour, white with deep spots of purple ; perfectly hardy in most parts of the country, but requires good soil and moisture. Flowers in August. Height, about 4 ft.

Lilium auratum platyphylum (Syn. *Lilium macranthum*). — A variety of *L. auratum* with very large flowers and foliage. The flowers average 10–12 ins. across and are

richly spotted. Flowers in August. Height, 2½–3½ ft.

Lilium Brownii.—This is sometimes described as *Lilium japonicum Brownii.* It has very large trumpet flowers, the petals of which are reddish-brown on the outside. Very hardy. It requires good soil and flowers at the end of June. Height, about 2 ft.

Lilium bulbiferum.—Red flowers, slightly cottony on the outside of the petals, and forms small bulblets in the axils of the leaves. A dwarf variety flowering in June. Height, about 12 ins.

Lilium canadense.—The CANADIAN LILY, with attractive bell-shaped flowers of varying colour from yellow to orange, produced in July. Height, 3 ft.

Lilium candidum. — The well-known white MADONNA or ST. JOSEPH'S LILY.[1] Very hardy, but much resents being moved. Flowers are large, with broad white petals; given in June and July. Height, 4–5 ft.

Lilium carniolicum.—Red flowers, after the type of *Lilium chalcedonicum,* in July. Height, about 3 ft.

Lilium chalcedonicum. — The SCARLET TURK'S CAP LILY, one of the best of the Martagon type. Very hardy, and flowers in July. Height, 3–4 ft.

Lilium chalcedonicum maculatum. —This is an improved form of *Lilium chalcedonicum,* and very robust.

Lilium Columbianum. — Sometimes called *Lilium nitidum.* Flowers in July and August, bright golden with red spots. Height, 2½ ft.

Lilium coridion. — Flowers a beautiful shade of yellow, produced from June to July. Height, 1–1½ ft.

Lilium croceum.—Flowers superb orange. Splendid in cottage gardens. It blooms in June and July. Height, 3 ft.

Lilium dauricum. — A pretty yellow Lily dashed with red and spotted black, with flowers from three to six in an umbel, in June. Height, 2–3 ft.

Lilium elegans.—A very attractive sort with brilliant-coloured, cup-shaped blooms in May and June. Height, 12–24 ins.

Lilium excelsum.—Syn. *Lilium testaceum,* which see.

Lilium giganteum (NOBLE HIMALAYAN LILY). — Flowers white, streaked with purple inside, given in July and August. This sort has very handsome foliage. When soil is good, it grows about 10–14 ft. high. Hardy and well adapted for woodland planting.

Lilium Hansoni.—Golden-yellow, with black spots. Good for pot-culture. Hardy. It blooms in July. Height, 3–4 ft.

Lilium Henryi.—Flowers August and September. Lovely orange shade, with deep green foliage. Height, 6 ft., or more.

Lilium japonicum (Syn. *L. Krameri*).—An unusual pink and very beautiful Lily. It blooms from July to August. Height, 2½ ft.

Lilium longiflorum.—This is the old TRUMPET LILY, not much grown.

Lilium longiflorum eximium (BERMUDA EASTER LILY).—A Lily bearing large white flowers in July and August. Height, 2–3 ft.

Lilium longiflorum formosanum.—A white Lily which flowers in July. Height, 3 ft.

Lilium longiflorum giganteum.—An especially good plant of free growth having many flowers, which

[1] The Kew Authorities give BOURBON LILY as the English name for *L. candidum.* Very few gardeners know it by that name, however.—EDITOR.

last well when cut. Colour white, and blooms in August. Height, 2–3 ft.

Lilium longiflorum Harrisii.—This Lily is recommended as superior to the variety *L. l. formosanum*, as it can be forced better. Colour white, and blooms in June. Height, 1½–2 ft.

Lilium longiflorum Marhan.—A lovely hybrid Lily, orange, with streaks and spots of red-brown. It blooms in June and July. Height, 7 ft., when established.

Lilium Marhan Ellen Willmott.—A more robust form of *Lilium longiflorum Marhan.*

Lilium Martagon.—This is the MARTAGON LILY of gardens and the TURK'S CAP LILY of Kew, of which there are many forms.

Lilium Martagon dalmaticum.—Light to dark purple flowers in July. Height, 5–6 ft.

Lilium monadelphum.—Golden-yellow reflexed flowers; pollen bright scarlet. It blooms in June. Height, 3 ft.

Lilium monadelphum szovitzianum (*Colchicum*).—Clear straw yellow, spotted with black, rich brown anthers. It blooms in July. Height, 3–5 ft.

Lilium pardalinum (PANTHER LILY).—From California, and one of the most beautiful of hardy Lilies. Flowers in July, bright orange, spotted dark crimson. Height, 2–2½ ft.

Lilium Parryi.—A distinct Lily of a beautiful citron yellow, spotted with light chocolate brown. Lovely perfume. Flowers in July. Height, 3–4 ft.

Lilium pyrenaicum.—The YELLOW TURK'S CAP LILY. Flowers yellow, spotted black, in May and June. Height, 2 ft.

Lilium speciosum album Kraetzeri.—Pure white, with band of green down each petal. It blooms in August and September. Height, 3 ft.

Lilium speciosum magnificum.—A new Japanese variety rich ruby carmine, margined white. Spikes grow from ten to twenty flowers. It blooms in September. Height, 4 ft.

Lilium speciosum Melpomene.—Dark crimson purple with white; free flowering, and blooms in September. Height, 4 ft.

Lilium speciosum roseum and rubrum (Japanese).—Rose-coloured flowers, varying in depth of shade. Several varieties are found among these. All bloom in September. Height, 3 ft.

Lilium sulphureum (Syn. *Wallichianum superbum*).—This has tubular-shaped flowers, yellow inside, rosy-brown outside. It blooms in September. Height, 6 ft.

Lilium tenuifolium.—Bears many bright scarlet flowers in June, and is very graceful. Height, 1½ ft.

Lilium testaceum (Syn. *Lilium excelsum*).—A very free blooming hardy and stately Lily for any soil, with beautiful yellow flowers in June, on plants 2½ ft. high.

Lilium thunbergianum sanguineum.[1]—Vigorous and early, with light red flowers, and black spots, in May and June. Height, 1–2 ft.

Lilium tigrinum.[2]—The old species (*sinensis*). Richly coloured flowers. Grows well among grasses if the roots are not allowed to become too dry. Colour, orange. It blooms in June and July. Height, 4 ft.

Lilium tigrinum splendens.—Fine flowers, large spots, very high coloured. Makes a grand display

[1] The species *thunbergianum* is referred to *Lilium elegans* at Kew.—EDITOR.

[2] This is popularly known as the TIGER LILY.—EDITOR.

during August. Height, 5 ft. An improvement on *Lilium tigrinum.*

Lilium umbellatum.—Syn. *Lilium dauricum.*

Lilium Wallaceii.—A splendid graceful variety for August. Rosy and apricot tinted; thickly spotted. Requires moisture. Height, 2–5 ft.

Lilium washingtonianum. — A species from California, with long panicles of flowers; very fragrant. Colour, white to lilac. Flowers in June and July. Height, 4–5 ft.

E. H. H.

New Species.

Lilium Biondii.—This has bright orange flowers, which are speckled with black.

LILIUM.—See *LILIES.* See also under Lily in *WATER GARDEN: PLANTS FOR THE.*

LILY LEEK (*Allium Moly*). — See *ALLIUM.*

LILY OF THE INCAS (*Alstroemeria pelegrina*).—See *ALSTROEMERIA.*

LILY OF THE VALLEY (*Convallaria.* Nat. Ord. Liliaceæ).—Everyone knows and appreciates the small white, drooping bells of the Lily of the Valley. With the lapse of years numerous varieties or forms have appeared, but none is sweeter or more charming in every way than the native wildling of our British woods.

Culture: (*a*) Under Glass. — The perfecting of cold storage has enabled what are called "retarded crowns" to be put on the market practically all the year round, and has very much simplified the cultivation of these flowers under glass, as they may be had in bloom at any time in boxes or pots. The first essential is to start them in a cold frame, and to give them very little heat at any period of their growth. The "crowns" may be planted 1 in. apart, the roots being carefully covered with soil so as to leave no air spaces, and the actual crowns or tops left sticking up bare. Darkness is essential at the start. An inverted flower-pot, or heavy shading the glass of the frame, will accomplish this. A temperature of from 60–65° F. is sufficient for these retarded crowns. With regard to ordinary crowns, the English and so-called Berlin strains are the best, and may be boxed or potted from autumn onwards. It is said that a touch of frost in some way makes them more amenable to early forcing, hence it is well to untie the bundles of crowns when received and put them in by the heels until wanted. The first batch may be started about mid-November, but unless a steady bottom heat of 75–80° F. can be had it is far better not to attempt to flower them until much nearer their proper time of blooming. January will be quite soon enough to begin to pot up batches, which may then be placed in warmth (bottom heat if possible) at once, and kept in the dark until they are well on the way to bloom, when light must be gradually admitted and the plants hardened off.

(*b*) Out of Doors.—Either clumps or crowns may be used, and should be planted in a light rich soil, if possible in partial shade, although they grow quite well in the open if the position is not too hot. To ensure a succession of bloom use should be made of different positions, *e.g.* the two sides of a wall running N.E. to S.W. The wild native woodland form is very charming when introduced for this purpose into good garden soil. The writer knows a garden where there are splendid beds of these on the two sides of a fruit wall in a kitchen garden. An annual top-dressing of leaf-mould and rich old rotten manure is of great benefit to permanent beds. These need not be removed until the growing poverty of bloom gives

warning that the time for this operation has come.

Varieties or Forms.—The British Wild Lily of the Valley (*Convallaria majalis*) is probably the original type. It is much smaller than *Convallaria Fortin*, which is a new and desirable variety.

"Berlin" and "Dutch" crowns or clumps signify a form between our native wild Lily of the Valley and *C. Fortin*. They are quite large enough to be pleasing. These are what are usually planted in gardens.

A double form and a pale pink or flesh-coloured form are sometimes offered in lists.—J. J. & E. T. E.

See also *Medicinal Herbs*.

LILY: Water Garden Species.—See *Water Garden: Plants for the*.

LIMACIDÆ.—See Slugs and Snails in *Insect Pests*.

LIME.

The word lime does not mean anything much to chemists, for it is a vague word. To gardeners, however, it means a great deal—it may mean success or failure of their crops; but, alas, to them also it is a word of somewhat vague meaning.

Strictly speaking, lime should mean oxide of the metal Calcium; but it may mean slaked lime, *i.e.* water-slaked lime or air-slaked lime. Water-slaked lime is Calcium hydroxide, and air-slaked lime is a vague mixture of Calcium oxide, Calcium carbonate, or Calcium hydroxide. Flour-lime may mean extra pure Calcium hydroxide or Calcium oxide; conversely it may also mean ordinary commercial lime (often full of impurities, such as clay, etc.), which has been ground to the form of an impalpable powder. Lime-powder may mean ground chalk or ground limestone. Ground garden lime may mean ground quicklime, slaked lime, or even finely ground magnesian, or Derbyshire limestone. Spar-lime is generally finely ground calcite spar, but it may also mean a mixture of ground heavy-spar (sulphate of barium) and calcite, which will prove injurious to crops. Alabaster and Gypsum limes are usually finely ground sulphate of lime.

Lime and its Uses.—We have very little faith in the various brands of patent lime there are now on the market. Most of them are charged at fabulous prices, and the gardener is strongly advised to keep rigidly clear of them, or at least only to use them for small experimental work, unless he has a fortune to spend upon the garden. The best lime we know of is obtained by burning the Derbyshire or Yorkshire Mountain Limestone, so largely quarried in the Peak District and in North-West Yorkshire. Next best is the lime obtained from burning chalk from the Downs. The lime obtained by burning brashy Jurassic or Tertiary limestones is very inferior, and should not be used if other is available. Magnesian Limestone, known to geologists as Permian Limestone, does not make good material for the garden, nor does the Limestone found in thin bands between the New Red Sandstone. Yorkshire and Derbyshire Mountain Limestone are renowned for their purity, and so should be used if possible.

With rare exceptions it is far better to buy lime in the form of freshly burnt lumps unbroken as they come from the lime kiln. Ground quicklime and flour-slaked lime are awkward to manage; the former is apt to burst its bags by absorbing atmospheric moisture, and as great heat is produced during the absorption the bags may char.

Both the materials unless stored in extra thick bags greedily absorb carbon dioxide from the atmosphere, and this means that their value is much reduced. When a piece of quicklime is put into a saucer of water it should at once start to crack and swell, giving off steam and falling to a fine powder. If it does not do this, either it has been burnt very badly, or it has absorbed so much carbonic acid gas from the atmosphere that the lime has become chalk. In any case it is not much use on a heavy soil where active quicklime is wanted. The amount of carbonate (which should never exceed 2 per cent. in any fresh sample) may be estimated roughly by weighing a sample, and weighing a dish containing dilute hydrochloric acid. Add the lime. Cover with a weighed watch-glass and allow to stand. When action has completely ceased weigh again, subtract from total weight, and you have weight of gas given off. Calculating amount of gas given off to be 44, add 56, and you have the weight of carbonate of lime in the sample. As to storing either lump or ground quicklime or slaked lime we do not advocate bags, unless the material is to be used almost immediately. We prefer to use closed barrels or deep tightly lidded boxes. If neither is available, make the lime into a heap in a shed and cover with a thick layer of dry earth, beating the surface hard. Once the lime is slaked the gardener cannot transform it again into quicklime, for though he may heat it in the ordinary way he cannot drive off all the water it has so greedily absorbed. Lime would want "burning" again before it could be transformed into its "quick" state, and this the gardener cannot do.

Well, now, about the use of lime. Gardeners, we may say, use it for two purposes: firstly, for chemically sweetening the soil by acting upon poisonous humic acids which have accumulated, and breaking them up into simpler compounds; and secondly, for mechanically improving the texture of the soil.

Now, as regards the former purpose, the use of lime must be regarded as being a strictly chemical one. A soil which has been generously manured with dung for many years is full of plant-food, but the plant-food is in a sour, poisonous form. Despite the richness of the soil, good crops of vegetables or a wealth of flowers cannot be obtained, simply because this plant-food is not available or is in an extremely unpalatable condition. Apply lime to the land, preferably quicklime or freshly slaked lime, digging it in freely, and in a very few weeks the complex compounds will have been entirely broken down, all the poisonous acids will have gone, and in their place are left useful, soluble lime compounds. Instead of the soil being acid, it is alkaline, and since most plants can thrive best only in an alkaline soil, we see the need for keeping a watch upon the soil to see when the lime supply in it is running out. The well-known test for lime—viz., treating some of the soil with dilute hydrochloric acid and assuming that if there is any effervescence this is due to carbonate of lime, hence concluding in that case that no lime is needed—should be applied to the soil every season, since if not there is no method of finding out when lime is needed. Lime is not necessary on soils which are of a chalky or limestone nature, for they inevitably contain as much of it as they require. On light soils chalk is the right material to use

(see later; also see article on *Chalk*).

As to the other action lime has, namely, that of improving the texture of the soil, this, though mostly a mechanical action, is not without its chemical side too. In a strong clay soil, for instance, the particles of clay are in an exceedingly fine state of division and very closely united; when such a soil is trenched and well limed, not one but two actions take place. First, the lime mechanically acts on the clay, making it granular and more workable; and secondly, the lime acts on it chemically, by breaking up the insoluble compound of double silicate of alumina and potash, turning out the potash and setting itself in place of it, thereby producing a double silicate of lime and alumina. This action of lime on clay soils is one of the utmost value to the gardener. What it means in a word is this: that when we want to give our clay soils a dressing of potash, which is very expensive, all we have to do is to give them a good dressing of lime, which is cheap. The potash is in the soil, and all we have to do is to unlock the door of the treasure-house by liming, and thus liberate the potash for our plants to feed upon.

The time to apply lime is an important question. Views on this point vary, but ours is that it is advisable to apply lime as a potash liberator when trenching clay ground as early as possible. If this work can be done in November, there should be a fine supply of potash available by the following March. Some people, however, fear to apply lime early, for they are afraid of losing some of the liberated potash. This seems a foolish idea. Clay soils are known to be retentive of moisture; thus the potash liberated cannot go far, and will in any case be within the reach of the plant's roots. As regards applying lime to sour land, *i.e.* land which may not be over-heavy but is full of humus, no good purpose can be served by using it earlier than the first week in February. In any case, the liming and digging should be completely done before the end of that month.

Some people say that lime can be applied at any time of the year. So it can, but there is not much gained by applying it to land after the crops have already been sown or planted, except in the case of using it for protecting them from slugs and snails. Lime must not be regarded as a stimulant as is sulphate of ammonia, for it is nothing of the kind.

Certain plants do not like lime. This applies to many shrubs, which are much injured by the use of it, also to certain rock plants and wild garden flowers. Generally speaking, it is a safe rule to go upon that plants which enjoy a peaty soil do not like and should never have lime. [The chief plants which dislike lime are mentioned in our article *Lime-Haters*.—Editor.]

When artificial manures, such as sulphate of ammonia and superphosphate of lime, are freely given to plants or crops, lime should in every case be applied early the following spring; for these two artificial fertilisers use up enormous quantities of lime, as they are what are known as "acid" fertilisers. The "after effects" from using these fertilisers, which are often so bad, would never be noticeable if lime were freely used upon the soil.

It was mentioned earlier that quicklime or slaked lime are not suitable for use on sandy soils, and that chalk is the right material to use. Why so? The reason be-

comes evident after a moment or two of consideration. Lime itself has a destructive action—we saw that it broke down the harmful acids in sour soils and the clay in strong soils, making them in each case into simpler compounds. In a sandy soil we do not require this destructive action: it is usually a matter of considerable difficulty to get any manure to remain "held" in the soil. What we want is a material with a "constructive" action, namely, something which will help to bind the particles of soil together, and help to hold the manure in the soil. This material is supplied by ground chalk, or better still, by powdered chalk-marl. These materials, applied in November, December, or even February, will do much more for the soil than ordinary lime could ever do, on account of the extreme difference of their action.

"Lime and animal manure should never be applied together." This old maxim, so often given, is seldom explained, and the average man asks, "Why?" To see why, he should scatter some freshly ground quicklime over some hot stable manure and then smell the strong ammonia which is given off. Every whiff of that ammonia means waste of plant-food; so the answer to the question above is, "Because one spoils the other."

Likewise, when mixing artificials together lime should be kept out of the way. Lime will drive all the ammonia out of salts, such as nitrate, phosphate, and sulphate of ammonia, replacing the base by itself and forming calcium phosphate, sulphate, and nitrate. With superphosphate lime has a rather different action. This fertiliser owes its solubility and its value as a plant-food to the fact that there is an excess of phosphoric acid in it far over and above the amount of acid needed to form a normal neutral phosphate of lime. The last-named salt is wholly insoluble in water and hence valueless for plant-food. Now, when superphosphate of lime and quicklime are mixed they act on each other and normal phosphate of lime is produced, which means that by mixing the two we are making a compound which is absolutely useless.

Lime should, however, be mixed with wet fresh vegetable refuse which we want to get decayed very quickly, for here its destructive chemical action is valuable. It is, however, a great mistake to mix it with leaves to hurry their decomposition, unless it is known for certain that they are to be used only for such plants as like lime.

Besides being used as a soil sweetener, etc., as mentioned, lime also finds other uses in the garden. It can be used for making lime water (see under CALCIUM HYDROXIDE).[1] Also it is freely used for making whitewash (see *ibid.*). As a shading for the glass of frames and greenhouses, there is nothing so good as painting the glass with a wash made from slaked lime or carbonate, and we might mention other uses.

Application of Lime.—We have now very briefly covered the ground taken under the heading of Lime. In this brief sketch we have tried to convey in a few simple, carefully chosen words, what other writers might require much more space to do. The subject of lime is a truly fascinating one, and such that plenty of original work awaits the man who cares to take the trouble to do it.

[1] This is regarded as a definite chemical compound, and as such it is treated in the next article.—EDITOR.

Work of this kind will well repay the hours spent on it.

Just a closing word about the application of lime. The rate of application varies with soil and season, but a safe early winter application is 8 oz. per sq. yard, and a safe early spring dressing 4 oz. per sq. yard. The lime lumps will slake themselves, and immediately they have fallen they should be dug in. For the amount of chalk to apply, see article on *CHALK* and notes on CALCIUM CARBONATE to follow.—E. T. E.

LIME COMPOUNDS.

Probably the lime compounds are more useful than are any others to the gardener. They are of many and varied natures, active and inactive, pleasant and unpleasant, as the following notes will show.

CALCIUM CARBIDE.—This in its fresh state is a grey, hard, lumpy material, which emits acetylene gas in contact with moisture. It is a powerful soil fumigant. Holes are made in the ground about 9 ins. apart each way and 9 ins. deep. Into each of these holes a little piece of the carbide is put, and immediately the holes are filled in. This should be done in the winter about the second week in November.

Calcium Carbide Refuse is the residue from lamps which are used for burning acetylene gas. It is more useful than the fresh carbide, and, like lime, is easy to apply. It is really a mild "gaslime." Used in the early winter, at the rate of 12–16 oz. per sq. yd., and dug in at once, it efficiently clears the soil of pests. It can be applied in the spring also, but if this is to be done it should be spread on the ground for a week and then dug in.

CALCIUM CARBONATE.—This is a useful material in many ways. The pure substance is known as precipitated chalk and is made in the process of making nitrate of potash by double decomposition with nitrate of lime (see CALCIUM NITRATE). Ground limestone is another form of it. This is a mild lime, and can be applied to sandy or acid soils with great advantage. It can be mixed with rotting vegetable matter to keep the whole sweet, and then the waste involved by mixing quicklime with it does not take place.

Ground chalk often contains impurities, and is regarded as an inactive and useless material for the gardener. On the contrary it is very useful, since it serves, as we saw in the article on *LIME*, to bind the material together if applied to light friable soils, thereby helping to prevent manure and plant food from being washed through into the subsoil and lost.

Lump chalk should be put on at the rate of 42–60 lb. per sq. rod early in November, and the weathered material dug in during the month of February.

Precipitated chalk can be freely mixed with potting soils, except for peat-loving plants, which do not like lime. It can be mixed with napthaline and other chemicals, and the material dug in as a soil fumigant. When in the special form known as "Whiting," it can be used for whitewashing. Mixing it with glue produces a milk which can be painted on glass to shade off too much sun. It and finely-ground limestone is invaluable for use in reclaiming peat lands for general crop cultivation.

CALCIUM CHLORIDE.—This is not of much use for outdoor work on the land, except as a means of conserving moisture. One oz. per sq. yd. in the spring will greatly help to keep the soil

damp throughout the season, provided, of course, that the chemical is not at once washed through into the subsoil. In the greenhouse it is very useful in winter weather for absorbing damp, and drying the atmosphere up. Pans of the chemical in lumps are put about the house, and when the chemical has dissolved in the water it has absorbed, the pan is merely put into the kitchen oven and the moisture evaporated off. The chemical can be used again and again.

CALCIUM CYANAMIDE.—When we refer to this, very often people think we are saying Calcium Cyanide. This is not the case. Cyanide of lime is poison, as are all cyanides, but Cyanamide of lime or calcium is a valuable plant food. It is made from calcium carbide, by passing nitrogen over the heated chemical, and in contact with water it evolves not acetylene gas but ammonia gas. The gas is given off slowly, and this makes it a lasting fertiliser. Calcium carbonate or precipitated chalk is produced at the same time.

Cyanamide is useful for all plants which require nitrogen either in a mild or active form. Root-crops benefit considerably as well as surface leaf crops by its use. It should be got on the land in the spring, a few weeks before sowing or planting, in order that its ammonia may be liberated. We may point out that up to the present the theory of scientists is that plants cannot absorb ammonia direct, but that it must first be changed by soil bacteria into nitrates. For this purpose lime is essential, and is supplied at the same time by cyanamide.

CALCIUM FLUORIDE is better known as Fluor Spar, and is useful for decorative purposes in the rock garden, for it is a glorious sky-blue in colour, almost as lovely as Labradorite in fact. It is of no use as manure, but as a source of hydrofluoric acid (see article on *Acids: Their Uses in Horticulture*) it is very valuable. The Blue Border (see article *Colour Gardening—Single-Colour Beds*), can, by the way, have its path spangled with fluor spar to improve its effect; for the spar is very cheap in Derbyshire.

CALCIUM HYDROXIDE.—This is slaked lime, a burning corrosive powder injurious to skin and clothes. Milk of lime is simply a mixture of slaked lime with water, made the consistency of skim milk. Lime water is made by putting a few ounces of slaked lime into a gallon of water, stirring up, and filtering, using the clear liquid only. Limewash is made from slaked lime also. Milk of lime can be used for softening temporarily hard water. Lime water is used for sweetening sour soil round the roots of pot plants, and for driving worms out of the soil in pots.

Calcium hydroxide readily absorbs carbon dioxide from the atmosphere, producing calcium carbonate. Slaked lime can be put on the land at the rate of 8 oz. per sq. yd. in November or February. It is much too active to be mixed with animal manures, and, like quicklime, it should on no account be mixed with sulphate of ammonia, superphosphate of lime, or any ammonia salts.

CALCIUM HYPOCHLORITE is better known as chloride of lime. It is prepared by passing chlorine over slaked lime. It is not of much use for the soil except as a cleanser. It will certainly kill pests, but it should be applied early, so that the poisonous chlorine may become disseminated before the

crops are put in. About 1 oz. per sq. yd. is an exceptionally safe dressing to apply, but three or four times this amount may be used.

CALCIUM NITRATE is a chemical of great importance. It is manufactured by cheap water-power and electricity in Sweden, by uniting the atmospheric nitrogen and oxygen, dissolving the gas in water and adding broken limestone. It is an exceedingly useful, soluble, nitrogenous manure, directly absorbable by plants; it is,[1] or was cheap, and hence can and should be widely used. Plants seem to love it, and although it is far more suitable for surface "leaf" crops, such as cabbages, spinach, etc., etc., very successful results have been attained by applying it to root-crops such as beet, carrots, parsnips, salsafy, and scorzonera which it is desired to hasten on in growth. About ½ oz. per sq. yd. can be applied once or twice during the growing season and hoed in, or ½ oz. per gallon of water occasionally will prove a useful liquid stimulant, but it must be kept off the leaves, or even at that strength it may burn them. Nitrate of lime is apt to absorb atmospheric moisture and dissolve itself therein, hence it must be stored in tightly-lidded tins or barrels.

Besides its direct uses, calcium nitrate has some very interesting minor uses. The important fact to remember in connection with it is that it is soluble in water, but other compounds of calcium, such as the sulphate and carbonate, are insoluble. Hence we can use it for "double decomposition" purposes, as chemists say, which means that we can use it for making one compound from another. This is specially useful in the case of potash. As is well known, carbonate of potash is cheap. Nitrate of potash is dear and very awkward to get for gardening purposes at any time.[2]

Nitrate of potash is, however, very much more useful to the gardener than carbonate of potash, or even sulphate of potash, so we proceed to turn carbonate of potash into nitrate of potash. This is easily done as follows:— A strong (nearly saturated) solution of carbonate of potash in hot water is prepared, and at the same time an equally strong and equally hot solution of nitrate of lime is made in another vessel. The two solutions are then mixed, stirred, and boiled. White precipitated chalk separates out. This is filtered off. More of the nitrate of lime is added in very small quantities until no further chalk is thrown down, and the solution is boiled away rapidly to about a quarter and cooled suddenly. Nitre separates out. The solution is then boiled down by about half, and again cooled suddenly. More nitre settles down, and this, with the former, is dried. The solution is then evaporated to dryness, and the nitre stored in tins till required for use. For amounts to apply, see POTASSIUM NITRATE in article *POTASH AND POTASSIUM COMPOUNDS*.

Again, we said that nitrate of potash was more useful than sulphate of potash, did we not? In the same way as that described above, nitre can be made from sulphate of potash and nitrate of lime, since sulphate of lime is not soluble.

Nitrate of lime can also be used for making nitrate of potash out of fresh wood ashes. For this purpose the ashes are heated with

[1] This article was written during the European War, 1914–18.

[2] During the War, nitrate of potash for this purpose could not be obtained for love or money.

hot water, and then, after filtering, a hot solution of nitrate of lime is added. Carbonate of lime is thrown down as before, and after the solution has been again filtered it is evaporated down as before.

CALCIUM NITRIDE would, if it were put on the market cheaply, be a most valuable fertiliser, and would soon supersede cyanamide. At present it is a chemical curiosity, and not in any manure merchant's list.

The other nitrides are prepared by passing nitrogen over heated metals, and surely nitrogen is cheap enough when four-fifths of the atmosphere consist of it. As is well known, calcium metal is easily made by electrolysis, and so there seems little excuse for urging attention to this chemical. The nitride would be a companion to calcium carbide, for the carbon in the carbide would be replaced by nitrogen. It would, of course, evolve much more ammonia than calcium cyanamide does, and would, instead of producing calcium carbonate as a by-product, produce the more useful hydroxide as the carbide does. We throw out this suggestion to manure makers with the remark that someone must be sleeping somewhere, or this material would have been on the market before.

CALCIUM ORTHOPHOSPHATES.—As mentioned under PHOSPHORIC ACID, in the article *ACIDS: THEIR USES IN HORTICULTURE*, some of the calcium phosphates are insoluble in water and thus very little use to the gardener. Tri-calcium and Di-calcium Orthophosphates are probably the two best known; they are also the two least soluble. Mono-calcium orthophosphate alone does not appear in any manure maker's list we can find, but again it is the most valuable of all. Mono-calcium orthophosphate, with a large proportion of sulphate of lime (insoluble) and other impurities, is sold as "superphosphate," but superphosphate is of small value compared to the enormous value of the mono-orthophosphate. We were under the impression that we had handled a sample of this, made from bones, but are informed now that it too is at present a chemical curiosity on account of some technical difficulty in its preparation. We hope that garden chemists will get to work on this matter at once so that before a second new edition of this book is issued it may be available at 3d. per lb. Another valuable orthophosphate of lime is or may be called Nitro-calcium orthophosphate. This too is not on the market (for why we cannot understand, since it is highly valuable). It is obtained by dissolving bones or other insoluble phosphate of lime (preferably tri-calcium orthophosphate) in nitric acid, and since both calcium nitrate and mono-calcium orthophosphate are soluble in water, a manure of the highest value is produced. Many experiments remain to be made with pure mono-calcium orthophosphate and nitro-calcium orthophosphate, but readers are recommended to begin using either at the rate of ¼ oz. per 2 gals. of water, and increase the strength gradually up to as much as ¾ oz. per gallon.

Superphosphate of lime is very useful for many crops. It induces early maturity. It may be said to be useful for all the crops of the triad, namely, leaf, root, and seed crops. As it is an acid manure it is essential that plenty of lime be mixed with the soil, but on no account must lime be mixed with superphosphate, since if it is, al

the mono-phosphate is changed into tri-calcium phosphate, which is insoluble. Nor should superphosphate be mixed with nitrate of soda or nitrate of potash, since a mixture reeking with nitric acid fumes will be produced—rank poison to crops.

Basic slag is another form of orthophosphate of lime. It is slightly soluble in water, and though it varies, the phosphate is in the form of the di-calcium-orthophosphate usually along with other impurities. Basic slag has many uses,—it is a good dressing for lawns, herbaceous borders, and general borders (4 oz. per sq. yd.), and for the vegetable garden it can be used at the rate of 6–8 oz. per sq. yd. In every case it should be applied very early in the winter, the sooner the better after the end of October. It must on no account be mixed with lime or ammonia salts.

Bones are another form of orthophosphate of lime, but as these are dealt with in a separate article we need not describe them here.

Of other phosphates, such as the Hypophosphates, Meta-phosphates, and Pyro-phosphates, there are great numbers, but as they are very little use to the gardener, we do not deal with them here.

CALCIUM OXIDE.—This (lime or quicklime) is fully dealt with in the preceding article.

CALCIUM SULPHATE.—This is dealt with in the article on *Gypsum*, to which the reader is referred.

CALCIUM SULPHIDE.—In contact with damp, this blackish compound evolves sulphuretted hydrogen, a remarkably filthy-smelling gas. Calcium sulphide is of little use save for a soil fumigant, and though it is praised by some people for this purpose, we do not think highly of it, and would prefer something a little more powerful and sweet-smelling in character. This material is, however, exceedingly cheap; it can be obtained as a free gift from most soda works, and we understand that it is applied at the rate of about 2 oz. per sq. yd. Its use as a fungicide has been suggested, but is still in the experimental stage.

CALCIUM SUPERPHOSPHATE.—This is not a true chemical compound, but is a mixture of soluble mono-calcium orthophosphate, insoluble calcium sulphate, and other impurities. See under CALCIUM ORTHOPHOSPHATES above.—E. T. E.

LIME FOR STONE FRUITS.—See *ORCHARD: MAKING AND MANAGEMENT OF.*

LIME-HATERS.

There are many families of plants to which the presence of lime in the soil is a vital necessity, if they are to attain their highest development; in less degree the greater number of plants appreciate its value in releasing the "locked-up" fertilisers of the soil. But, on the other hand, there are some plants which can be called "lime-haters," for they will not thrive where lime is found in the soil, and even its presence in the water is inimical to their well-being. This class is, however, a small one; though the list is considerably extended if we include those plants which, while not refusing to grow in a calcareous soil, are certainly better where this element is absent. In making the rock garden it is especially useful to know what plants dislike lime, as the soil can be prepared to suit their particular requirements. With regard to the ordinary occupants of borders and shrubberies, the list is comparatively small; but there is a large section of greenhouse plants in which lime should be excluded from

the compost. In the following lists the names of plants are those by which they are generally known and catalogued. They are not in all cases absolute lime-haters, but do best in soils free from lime.

Ferns.—Some of these require lime, some are indifferent, and others do poorly where it is present, preferring a peaty soil instead. Among the last-named class are the following: *Adiantum Capillus-veneris, A. pedatum*; Gleichenia in variety; Gymnogramme in variety; *Hymenophyllum tunbridgense*; Polypodium in variety; Todea in variety; and Trichomanes in variety.

Greenhouse and Stove Plants.—In this section the number of plants that do better without lime is fairly large, but as it is not usual to incorporate lime with the compost, there is little risk in most cases, although where the natural soil of the district is calcareous, it is advisable to procure potting soil from elsewhere. Among plants that may be so treated are the following: Acacia, Acalypha, Achimenes, Alocasia, Anthurium, Azalea, Bertolonia, Boronia, Bouvardia, Bromelia, Chorizema, Clerodendron, Columnea, Correa, Darlingtonia, Dillwynia, Dionæa, Dracæna, Drosera, Epacris, Eranthemum, Erica, Eriostemon, Gnidia, Hoya, Ixora, Leschenaultia, Lisianthus, Maranta, Medinilla, Monochætum, Nepenthes, Nidularium, Oxylobium, Pimelea, Plumbago, Rhododendron, Roella, Sarracenia, Sollya, Streptocarpus, Tetratheca, Tillandsia, Torenia, Tydæa, Utricularia.

Rock and Alpine Plants.—*Achillea ageratifolia, A. moschata; Androsace alpina, A. carnea, A. Chumbyi, A. ciliata, A. foliosa, A. glacialis, A. imbricata, A. Laggeri, A. lanuginosa, A. obtusifolia, A. wulfeniana; Anemone baldensis, A. sulphurea; Artemisia glacialis; Asperula suberosa; Campanula alpestris, C. excisa; Cathcartia villosa; Caulophyllum thalictroides;* Claytonia in variety; *Conandron ramondioides; Coptis trifolia; Cortusa Matthioli; Dalibarda repens* (Syn. *Rubus Dalibarda*); *Daphne Genkwa; Deinanthe bifida; Dianthus glacialis, D. neglectus; Diphylleia cymosa;* Dodecatheon in variety; Douglasia in variety; *Eomecon chionantha; Epigaea repens;* Erica (except *E. carnea*, which does not resent lime); *Eritrichium nanum;* Erythraea in variety; *Gaultheria procumbens; Gentiana Pneumonanthe, G. pyrenaica; Geum reptans; Haberlea rhodopensis, H. r. virginalis; Helionopsis breviscapa;* Hudsonia in variety; *Iris cristata; Jankaea Heldreichii; Jeffersonia binata;* Laurentia; *Linnaea borealis;* Lloydia in variety; *Loiseleuria procumbens; Lychnis alpina; Malvastrum coccineum;* Meconopsis in variety; *Menziesia caerulea; Mitchella repens, M. nudulata; Parochetus communis; Philesia buxifolia; Phyteuma hemisphaericum, P. pauciflorum;* Pinguicula in variety; *Primula hirsuta, P. viscosa;* Rhododendron (*R. ferrugineum* and *R. racemosum* are exceptions); *Saxifraga androsacea, S. Brunoniana, S. Hirculus, S. Seguieri; Scoliopus Bigelovii; Sempervivum arachnoideum, S. Gaudinii, S. Wulfeni; Silene Pumilio, S. rupestris, S. vallesia;* Sisyrinchium in variety; Swertia in variety; *Tanakaea radicans;* Thlaspi in variety; *Trifolium alpinum; Valeriana celtica, V. supina; Vancouveria hexandra; Viola pedata, V. valderia;* Wulfenia in variety.

Shrubs and Miscellaneous Plants.—Andromeda in variety; *Anemone nemerosa; Arctostaphylos Uva-ursi;* Azalea in variety; *Bruckenthalia spiculifolia; Bryanthus empetriformis;* Calluna in variety; *Calo-*

pogon pulchellus; Clethra alnifolia; Cornus canadensis; Daboëcia (Syn. *Menziesia*); *Empetrum nigrum; Epigaea repens;* Erica (but *E. carnea* will thrive in chalky soil); *Fabiana imbricata;* Fothergilla; *Gaultheria procumbens, G. Shallon;* Kalmia in variety; Ledum in variety; *Leiophyllum buxifolium* (Syn. *Ledum*); Menziesia in variety; *Oxycoccus macrocarpus, O. palustris* (Cranberry); Pernettya in variety; *Philesia buxifolia;* Pieris in variety; Polygala in variety; Rhododendron in variety (but *R. hirsutum* and *R. racemosum* can be grown on calcareous soil); Vaccinium in variety (including *V. Myrtillus*, the Whortleberry or Bilberry).—W. J. C.

LIME PLASTER.—See *MORTAR.*

LIME SALT WASH and **LIME SULPHUR WASH.**—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION.*

LIME SULPHUR.—See *SPRAYING MIXTURES AND FUNGICIDES.*

LIME TREE.—For the best sorts see under TILIA in *TREES.*

LIMESTONE.—See *ROCKWORK.*

LIMESTONE POLYPODY (*Polypodium Dryopteris Robertianum*).—See *FERNS AND FERN GARDENING.*

LIMING.—See *SOIL IMPROVEMENT.*

LIMNANTHEMUM (Nat. Ord. Gentianaceæ).—Only three species of this genus are at all generally grown. These, *L. humboldtianum* (Syn. *Villarsia humboldtiana*), *L. lacunosum,* and *L. peltatum* (Syn. *Villarsia Nymphoides*), which last is better known as the FRINGED BUCK BEAN, are all good hardy aquatics and may be grown in the usual way for water garden plants. They are easily propagated by offsets and spread rapidly. The first bears yellow and white flowers, while the second and third are pure yellow. All bloom in June or July, and average 3–12 ins. high.

LIMNANTHES (Nat. Ord. Geraniaceæ).—This includes two dwarf hardy annuals which are free-flowering and effective. They are easily raised from seeds sown in autumn or spring, and are of somewhat trailing habit.

Limnanthes alba.—This is a white summer flowering sort, growing 6 ins. high.

L. Douglasii.—This is a yellow and white sort which flowers freely in the summer and early autumn; its variety *rosea* is pink. Both grow about 1 in. high.

LINARIA.—This pretty genus is described under its English name *TOAD FLAX.*

LINDENBERGIA (FIGWORT. Nat. Ord. Scrophulariaceæ).—This is a shrubby greenhouse plant, bearing bright yellow Mimulus-like flowers in great abundance. The leaves are egg-shaped, and the plant remains in flower three months. It is propagated by cuttings in the spring in slight bottom heat, and should be potted in light loam, peat, and sand. Temperature required, 50–55° F.

Greenhouse Species.—*Lindenbergia grandiflora.*—Yellow. Flowers from November to March. Height, 1–3 ft.

LINEAL MEASURES.—See under MISCELLANEOUS MEASURES in *WEIGHTS AND MEASURES.*

LING.—See CALLUNA in *SHRUBS.*

LINNAEA (TWIN FLOWER. Nat. Ord. Caprifoliaceæ).—Only one species of this genus is usually grown. This is a pretty trailing plant with wiry stems, suitable for moist shady situations. It is propagated by dividing the roots or by layering.

L. borealis.—This pretty plant has small round leaves on twiggy stems. Flowers fragrant rose-pink, in twos, on slender stems. Flowering Period, May to July. The variety *americana* has larger leaves and flowers.

Both it and the type average 3 ins. high.

LINOSYRIS.—Now included in the genus *ASTER*.

LINSEED.—See under FLAX in *MEDICINAL HERBS*.

LINUM (Nat. Ord. Linaceæ).

One member of this genus (*L. grandiflorum*) is a very popular annual in gardens, and deservedly so, as it flowers with the utmost freedom, is quite hardy, and grows freely from an outdoor sowing in spring. The plants are elegant and graceful; they are also quite useful for greenhouse decoration if grown in pots. Their flowers are rose-coloured, but there are also blue and crimson varieties, all of which flower freely in the summer or autumn. The height averages 6–12 ins.

Perennial Border Species.—*Linum perenne* (PERENNIAL FLAX) is a plant of very easy culture, and is useful in the herbaceous border. It bears blue flowers from June to August, and grows about 1½ ft. in height.

Rock Garden Species.—These are perennials of light graceful habit, suitable for open sunny places in the rock garden. They are propagated by means of cuttings in July or seeds in spring.

Linum alpinum.—A dwarf tufted plant with slender stems. Flowers blue. Site sunny. Soil sandy loam, gritty. Flowering Period, June to August. Height, 9 ins.

L. flavum.—A bushy plant. Flowers deep yellow. Site open. Soil loam. Flowering Period, June to September. Height, 1 ft.

L. salsoloides.—A slender-stemmed sort with narrow leaves. Flowers pale pink, with darker veins. Site sunny. Soil rocky. Flowering Period, June to July. Height, 9 ins. Its variety *nanum* is a dwarf compact kind only 4 ins. high.

See also FLAX in *MEDICINAL HERBS*.

LION'S EAR (*Leonurus grandiflora*).—See *LEONURUS*.

LION'S LEAF (*Leonotice Leontopetalum*).—See *LEONOTICE*.

LION'S TAIL (*Leonurus grandiflora*).—See *LEONURUS*.

LION'S TURNIP.—A name applied to *LEONOTICE*, which see.

LIPASE.—A ferment necessary for successful germination. See *GERMINATION OF SEEDS*.

LIQUID MANURING.—See *FEEDING PLANTS*.

LIQUIDAMBAR.—For the best species see *TREES*.

LIQUORICE.—See *MEDICINAL HERBS*.

LIRIODENDRON.—For the best species see *TREES*.

LITERATURE OF THE GARDEN.

The dawn of horticultural literature begins with the old Greek geoponic writers. In their works are to be found many useful and interesting references to the cultivation of plants and gardens.

The Romans, too, have contributed their quota in days gone by; especially worthy of mention are Cato, Varro, Columella, whose tenth book of *De Re Rustica* is a poem on gardens, and Palladius. The "Georgics" of Virgil may certainly be claimed as coming within our subject, for in them he treats of the culture of the vine and the olive. Pliny the Elder in his *Historia naturalis* has much to say about gardens and their occupants, but the space allotted to us for our subject precludes anything like a dissertation upon the writings of these old time authors. Translations of all of them can easily be procured if required.

There is a great gap in our subject between the fall of the Roman Empire and the revival of learning in the Middle Ages. Some famous works written in Latin and in manuscript made their appearance before the printing press became known. One of them in particular, by an author named Petrus de Crescentiis, entitled *Le Livre des prouffits Champestres et ruraulx*, richly illuminated, a French translation from the original Latin edition, sold a few years ago for the sum of £2600.

But for the modern gardener, whose interest lies chiefly in books of a less pretentious character, the literature

of the garden here in England begins in the sixteenth century. To go beyond English horticultural literature would occupy more space than is possible, although it is curious that many of our early gardening treatises were admittedly translations from French and other foreign authors.

The first to be mentioned is *The Grete Herball*, the forerunner of a whole series of similar productions. They were partly medical, partly horticultural; herbs and simples, fruits and flowers with their curative properties, often more fanciful than real, were the distinguishing features of these early works. It is stated that the first edition of the *Herball* appeared in 1516, but none earlier than 1526 is now known. It was reprinted at intervals by one Peter Treveris, and was evidently either wholly or in part a translation from another famous book in French, *Le Grant Herbier*.

Next on our list is, of course, the famous *Gerard's Herbal*, which first saw the light in 1597, a second edition appearing in 1633. These old herbals like many other books on agriculture and allied subjects were not exclusively horticultural. The garden book pure and simple was a gradual and later development, and was, so to speak, evolved little by little as time went on.

It is no part of our purpose to fill this modest article with titles of famous books and the names of illustrious authors; it cannot be done. They are far too numerous, and so it will be of much greater service to the reader if we indicate sources of information upon such subjects as he may require. For Herbals, then, we recommend Mrs. Arber's *Herbals: Their Origin and Evolution* (Cambridge University Press, 1912), copiously illustrated with numerous reproductions of quaint woodcuts from many a famous old book difficult of access to the ordinary reader.

The next kind of book to which attention may be drawn is the agro-horticultural book, of which a large number appeared soon after printing became common. These will be found enumerated in most of the horticultural bibliographies; the cultivation of orchards and kitchen gardens largely occupied the attention of our English writers about the end of the sixteenth and the beginning of the seventeenth centuries.

Quite a number of them were translations from French and other Continental writers. Thomas Tusser, Thomas Hill, Leonard Muscall, Gervase Markham, William Lawson, Samuel Hartlib, Ralph Austen, being famous names at this period.

On the Continent, as we have already indicated, there were many eminent and capable cultivators who published important publications dealing with many phases of the gardener's craft. Estienne's *Maison Rustique*, of which more than one hundred editions were published in France, appeared several times in English. John Evelyn's *The French Gardiner* was a translation, as also was his *The Compleat Gardiner*, the latter originally written by the great Frenchman Jean de la Quintinye. A little later two famous French books were translated by London and Wise, well-known nurserymen in their day, and almost simultaneously by an anonymous translator. They were known in the originals as *Le Jardinier Solitaire* and *Le Jardinier Fleuriste*, but in the English editions they were both embodied in one volume and known as *The Retir'd Gard'ner*. This took place in 1706, and eleven years later a further edition of London and Wise's translation appeared by John Carpenter. An abridgment of the great La Quintinye's work was also issued by London and Wise in 1699, rapidly passing through several editions, and this kind of literary activity unquestionably contributed very largely to an extension of our horticultural knowledge in those days.

This brings us to the beginning of the eighteenth century. Gardening Literature had then begun to assume an importance far surpassing anything that had preceded it. Among famous names Richard Bradley, John Lawrence, Stephen Switzer, Batty Langley, John Abercrombie, Richard Weston—in whose work *Tracts on Practical Agriculture and Gardening* is to be found one of the first bibliographies of interest to the garden book lover—Sir Uvedale Price, and Humphry Repton, are worthy of mention in their respective departments of knowledge.

When we get well into the eighteenth century the name of Philip Miller, "Hortulanorum princeps" as he was called, curator of the Chelsea Physic Garden, looms largely before us. Besides his other writings, *The Gardener's and Florist's Dictionary*, a huge folio that ran into no fewer than

eight editions, will for ever preserve his memory. There were other gardeners' dictionaries, such as John Dick's *The New Gardener's Dictionary*, fol. 1771, and Alexander Macdonald's *A Complete Dictionary of Practical Gardening*, in 2 vols., 4to, 1807, but all of these, except for purely antiquarian purposes, are now superseded by George Nicholson's modern work, *The Illustrated Dictionary of Gardening* and *Supplement*, in 5 vols., 4to.

It is just at this point that it seems to be useful to insert a few notes on some of the authorities on garden bibliography to which the reader may refer in case of need. For French horticultural literature there is probably no more useful work than the library catalogue of the National Horticultural Society of France and Georges Gibault's *Étude sur la bibliographie et la litterature horticoles et anciennes*. An excellent idea of German garden books can be got from Dochnahl's *Bibliotheca Hortensis*, which contains particulars of all such works as were published in Germany between the years 1750 and 1860.

Italian garden literature is not extensive; the best paper on the subject is to be found in Loudon's *Gardener's Magazine*, vol. xvi., 1840, p. 70, where *The Garden Literature of Italy* is very ably discoursed upon by Sig. Giuseppe Manetti.

The late William Paul, the great English rosarian, read a paper *On the Literature of Ancient and Modern Gardening* before the Royal Society of Literature in 1887. It will be found in his *Contributions to Horticultural Literature*, p. 532. There are, to choose only a few at random, bibliographical lists of more or less importance in *The Hortus Kewensis*, 2nd edition, 1813; Loudon's *Encyclopædia of Gardening*; Friend's *Flowers and Flower Lore*; Inigo Trigg's *Garden Craft in Europe*; but more strictly limited to purely English garden bibliography are the lists in Johnson's *History of English Gardening* and the Hon. Mrs Evelyn Cecil's *A History of Gardening in England*.

Unfortunately the last two do not go far beyond the third decade in the nineteenth century, since which period there has been an enormous influx of books on every conceivable subject connected with the many branches of horticulture.

In floriculture alone, to say nothing of the flower garden in general, there are hundreds of books, pamphlets, and treatises old and new. Special monographs have been published on every kind of florists' flower, the rose, dahlia, chrysanthemum, carnation, sweet pea, pansy, etc. What Pritzel's *Thesaurus Literaturae Botanicae* does for the Student of Botany, so the writer's *The Florist's Bibliography*, the only work of its kind, does for the literary lover of flowers. And a modern feature of floral Bibliography should here be mentioned, *i.e.*, the Year Books or Annuals of the various special Floricultural Societies, in which publications much statistical and other matter of interest to their members are to be found. John Parkinson's *Paradisi*, published in 1629, is about one of the first of florists' books, a modern reprint of which in facsimile can be had.

The art of garden design has been very fully dealt with from quite early times. Many and acrimonious are the discussions that have taken place in connection with this subject. Writers on various aspects of landscape gardening and garden planning are John James, who translated *The Theory and Practice of Gardening* from the French, George Mason, Horace Walpole, Thomas Wheatley, William Gilpin, Richard Steele, Sir Uvedale Price, Humphry Repton, John Claudius Loudon, and many others, without coming down to modern authorities. Their names constantly recur.

Not wholly remote from the last subject are garden poems. Some of these have been very famous and have achieved a degree of popularity that we can hardly understand to-day. Abraham Cowley's one on *The Garden* is reprinted to-day. Some, inspired no doubt by the "Georgics" of Virgil, may be briefly recalled. Rapin's *Hortorum, Libri IV.*, has not only been translated into French, but has found two English translators in the Rev. J. Gardiner and J. Evelyn. The Abbé Delille's poem *Les Jardins*, which has run into over a hundred editions, has also been translated into our tongue. Dr Erasmus Darwin, the grandfather of the great scientist, Charles Darwin, was the author of *The Botanic Garden*, a poem in two parts. Another one, *The English Garden*, by the Rev. William Mason, in four books, was first published in 1772. See also our article on GARDEN POETRY.

We are led imperceptibly in this

way to the modern development of the literary as distinct from the practical garden book. Nowadays there are so many, that a special classification is almost necessary to deal with them. Artistic printing and binding, the mechanical processes of inexpensive illustration both in colour and in black and white, have helped very materially towards an almost unrestricted output.

Only a few of the interesting literary garden books can be mentioned. We shall select those that the book lover may well place upon his shelves, to take down at quiet intervals, in leisure moments, to dip into, and thus taste the pleasures of the past. First of all comes Forbes Sievking's *The Praise of Gardens*, a choice collection of extracts from authors who have written about gardens, dating back to the days of the ancient Egyptians. Hazlitt's *Gleanings in Old Garden Literature* comes next. Then Ellacombe's *Plant Lore of Shakespeare* and Friend's *Flowers and Flower Lore*. If we dared to encroach still further on our space we might easily increase this meagre list, but we have yet other subjects to broach.

Pomology, Vine Culture, Vegetable Growing, Rock Gardening, Orchids, Ferns, Glasshouse Management and other branches of the gardener's art have practically libraries to themselves. Books on these subjects are innumerable, and in most cases the practical cultivator will only be concerned with the latest and most up-to-date edition. These are constantly changing and, being subject to revision, are outside the scope of our present purpose. Many of the great publishing houses keep in stock and can supply the latest editions of the most popular works of our great modern authorities on gardening subjects.

By the beginning of the nineteenth century ornamental as well as practical gardening had become an established art, and an eagerness had become manifest among its devotees to acquire useful knowledge in its various branches. The old ponderous tomes in folio and quarto were expensive and awkward, and ere long the development of serial or periodical garden literature was to become an established fact.

The Botanical Magazine was begun by William Curtis in 1787 and continues to this day. A coloured plate of a new or rare flower, with two pages of descriptive letterpress to accompany it, was the style in which it was brought out. *The Botanical Register* was very similar in style, and others followed, but periodical gardening literature as we know it to-day did not exist. The start was made when John Claudius Loudon, one of the greatest literary horticulturists we ever had, issued the first number of his *Gardener's Magazine* in 1826, and continued it to the day of his death in 1843.

This magazine was a most remarkable production in every sense of the word. Its contents were varied, embracing every department of horticulture and allied subjects; its contributors were eminent men living in all parts of the world; its influence was universal.

Loudon was a most prolific and voluminous author, a great number of important works issuing from his pen. His *Encyclopædia*, his *Arboretum et Fruticetum*, are monuments of patient toil. His wife after his death continued to revise and issue new editions of his and her own numerous works.

The Gardener's Magazine was shortly after its foundation followed by other monthly publications of a similar kind. Some were illustrated in a poor way with coloured plates most crudely done. *The Floricultural Cabinet*, edited by Joseph Harrison, appeared in 1833, and ran on until 1860 when it was merged in another, a weekly publication also called *The Gardener's Magazine*. Marmock's *The Floricultural Magazine* followed in 1836, and several others about the same time. *The Florists' Journal* was started in 1840. *The Florist*, which subsequently continued as *The Florist and Pomologist*, was first issued in 1848. *The Midland Florist* began in 1847, and so for a time these sixpenny or shilling monthlies answered the purpose of keeping the public up to date in the novelties of the day, the reports of the shows and the latest cultural devices. As time went on and education improved among the gardening fraternity, these old monthlies were not deemed to be sufficiently frequent in their appearance, and a demand for the weekly gardening press developed.

The Gardener's Chronicle was started in 1841, and still continues. Other weeklies followed, namely, *The Cottage*

Gardener, developing into *The Journal of Horticulture*; *The Gardener's Magazine*, long edited by Shirley Hibberd, a versatile and highly accomplished journalist; *The Garden*, a high-class weekly founded by William Robinson, well known for his work in horticulture. The cheaper but probably more popular penny gardening press was founded by William Robinson in *Gardening Illustrated*. Rival competitors soon followed, *Garden Life*, *Garden Work*, *The Gardening World*, *Amateur Gardening*, *The Gardener*, and others. The great war, however, resulted in the discontinuance of several of the latter-day weeklies.

It is proper to remark, before closing our paper, that another form of horticultural periodical has exercised a considerable influence on the public to whom it is specially addressed. We refer more particularly to the *Journal of the Royal Horticultural Society*, a veritable mine of inexhaustible horticultural knowledge on every conceivable subject directly and indirectly concerning the garden, the orchard, the greenhouse, and, in fact, all branches of practical and scientific gardening.

C. H. P.

LITHOSPERMUM (GROMWELL. Nat. Ord. Boraginaceæ).—This is a genus of sub-shrubby plants, mostly of prostrate habit. Sunny positions and well-drained sandy loam are essential for nearly all the species, which are propagated by cuttings in July and also by division in spring. The following are the best and are suitable for the rock garden:—

Lithospermum graminifolium.—This bears tufts of grass-like foliage and deep blue flowers. Site sunny. Soil gritty. Flowering Period, June to August. Height, 9 ins.

L. prostratum.—This forms a mass of twiggy stems covered with dark green leaves. Flowers gentian blue. Site sunny ledge or retaining wall. Flowering Period, May to September. Height, 4 ins. The variety *caeruleum* (Syn. *Heavenly Blue*) bears pale blue flowers.

L. purpureo-caeruleum.—This is a strong-growing trailer. Flowers red at first, turning to purple. Site, half-shade. Soil strong loam. Flowering Period, May to September. Height, 1 ft.

LITHOSPERMUM MILDEW.—See *DISEASES OF ROCK PLANTS*.

LITOBRACHIA.—Now included in the genus PTERIS, for which see *FERNS AND FERN GARDENING*.

LITTLE ERMINE MOTHS.—See *INSECT PESTS*.

LITTLE QUAKING GRASS (*Briza gracilis*).—See *ORNAMENTAL GRASSES*.

LITTORELLA (Nat. Ord. Plantaginaceæ).—The little dwarf-growing white-flowered SHOREWEED which many of us have been so pleased to find in damp sandy corners on the beach at the seaside is botanically known as *Littorella juncea* (Syn. *L. lacustris*). It does not succeed very well in inland gardens, so is best left where it is.

LIVER OF SULPHUR.—See POTASSIUM SULPHIDE in *SPRAYING MIXTURES AND FUNGICIDES*. See also POTASSIUM SULPHIDE in *POTASH AND POTASSIUM COMPOUNDS*.

LIVING FENCES.—See *GARDEN FENCES*.

LIVISTONA.—For the best species see *PALMS*.

LIZARD ORCHIS (*Orchis hircina*).—See note at end of *HARDY ORCHIDS*.

LOASA (Nat. Ord. Loasaceæ).

This is a genus which may well be dispensed with except in the largest collections. It contains many hardy and half-hardy annuals, as well as some half-hardy biennials and half-hardy shrubs, some of a trailing and climbing habit. Most of the plants have very poisonous properties, and sting the flesh violently when touched. Probably the best known species is *L. lateritia*, the CHILI NETTLE, a half-hardy red, May flowering climber, averaging 12 ft. or more in height.

LOBARIA.—Now included in the genus *SAXIFRAGA*.

LOBB'S ARBOR VITAE (*Thuya gigantea*).—See *TREES*. This species is now referred to *Libocedrus decurrens* and *Thuya plicata* by the Kew Authorities.

LOBB'S NASTURTIUM (*Tropaeolum lobbianum*).—See *CLIMBING AND TRAILING PLANTS*.

LOBELIA (Nat. Ord. Campanulaceæ).—Florists' section, half-hardy annuals and herbaceous perennials, 6–36 ins. high.

Soil.—Annual sorts succeed in ordinary garden soil. The Cardinalis varieties require light, but extremely rich, garden soil. Propagation is by seed, cuttings, and division, the first method being preferable for the annuals, and the other two for the herbaceous perennials.

Culture.—Sow the seed in March in slight warmth, pricking off as soon as the seedlings are easily handled, and plant out about the end of April or in May. If cuttings are wanted, the old plants should be potted up in autumn and placed in a cool greenhouse. During winter they must be kept fairly dry, otherwise they are liable to damp off. In February or March remove the young growths, and insert in sandy soil, where they will soon root.

USES.—The annual blue lobelia makes a useful and popular edging plant for summer bedding; it lasts long in bloom, and supplies a much-wanted colour amongst dwarf-growing flowers.

The cardinalis, fulgens, and syphilitica species and their hybrids are useful plants in borders where abundant moisture is obtainable, their brilliant colours and tall growth being very attractive in July and August. The roots require slight protection in winter.

Varieties. — *Annual.* — Crystal Palace compacta, Halley's Blue, Oxonion, Perle d'Azure.

Herbaceous.—Cardinalis, Crimson Beauty, De Breusen, Firefly, Gloire de St Anne's, Queen Victoria.

J. L. G.

LOBLOLLY, or LOBLOLLY PINE (*Pinus Taeda*).—See *TREES*.

LOBULARIA.—Now included in the genus *ALYSSUM*.

LOCUST ACACIA (*Robinia Pseudacacia*).—See *TREES*.

LOGANBERRY.—See *BRAMBLES AND BERRIES* and *BUSH FRUITS*.

LOISELEURIA (Nat. Ord. Ericaceæ).—A trailing shrubby plant, which thrives in sandy peat in a cool, moist position in the rock garden, and is propagated by cuttings in autumn. One species is in cultivation:—

Loiseleuria decumbens (TRAILING AZALEA).—A prostrate plant with wiry stems and small leaves. Flowers light purple. Flowering Period, June to July. Height, 3 ins.

LOLIUM (RYE GRASS. Nat. Ord. Gramineæ).—This is a genus of more importance to the farmer than the gardener. It is, however, used to some extent as a green manure crop, especially ITALIAN RYE GRASS, which is botanically known as *L. multiflorum* (Syn. *L. italicum*). Two other forms used to a more limited extent for the same purpose are DARNEL (*L. temulentum*) and RED DARNEL (*L. perenne*), of which a synonym is *L. linicolum*.

LOMARIA.—For the best species and varieties see *FERNS AND FERN GARDENING*.

LOMBARDY POPLAR (*Populus nigra pyramidalis*).—See *TREES*.

LONAS.—See *EVERLASTING FLOWERS*.

LONDON PLANE (*Platanus acerifolia*). See *TREES*.

LONDON PRIDE (*Saxifraga umbrosa*). See *SAXIFRAGA*.

LONDON PURPLE.—See *INSECT PESTS: GENERAL METHODS OF DESTRUCTION*.

LONDON ROCKET.—See *SISYMBRIUM*.

LONICERA.—For the best species see *CLIMBING AND TRAILING PLANTS* and *SHRUBS*.

LOOFAH.—See *ORNAMENTAL GOURDS*.

LOOPERS.—See under WINTER MOTHS in *INSECT PESTS*.

LOOSESTRIFE.—See *LYSIMACHIA*.

LOOSESTRIFE (*Lythrum*).—See *WATER GARDEN: PLANTS FOR THE*.

LOPHOLEPIS.—Now included in the genus POLYPODIUM, for which see *FERNS AND FERN GARDENING*.

LOPHOSPERMUM.—See *ANNUALS, HALF-HARDY: LIST OF*.

LORE OF THE GARDEN.—See *GARDEN LORE*.

LORETTE SYSTEM OF PRUNING.—See under SINGLE CORDONS in *CORDON FRUIT TREES*.

LORINSERIA.—Now included in the genus WOODWARDIA, for which see *FERNS AND FERN GARDENING*.

LOTUS (BIRD'S-FOOT TREFOIL. Nat. Ord. Leguminosæ).—The true Lotus is a modest plant as compared with the Lotus-flower of the East, of poets, and of mythology. Although this genus contains several hardy annual species, only one possesses real garden value, and this is *L. Tetragonolobus* (Syn. *Tetragonolobus purpurea*), which bears dark purple flowers from June to August, on plants 6–12 ins. high. It is quite hardy, and is easily raised from seeds sown in the open in early spring or late summer. The best site for it is a sunny position in the rock garden, where a light soil can be given it.

Hardy Perennial Species.—These are useful plants for banks and the less choice section of the rock garden. They may also be well grown in herbaceous borders. They require any ordinary moderately light soil in a sunny position, and are not difficult to propagate from cuttings inserted in July out of doors, or by division of the roots in the autumn or spring, at which time they may suitably be planted. We describe a few of the best species below:—

Lotus corniculatus (Syn. *L. crassifolius*).—A yellow August flowering sort, growing about 6 ins. high.

L. major.—Syn. *L. uliginosus*, which see.

L. maritimus.—Syn. *L. siliquosus*, which see.

L. ornithopodioides.—A yellow June flowering species about 6 ins. high.

L. pilosus.—Syn. *L. uliginosus*, which see.

L. siliquosus (Syn. *L. maritimus*).—A yellow June flowering sort about 4 ins. high.

L. tenuis.—A yellow sort blooming in July, which grows about 1 ft. high.

L. uliginosus (Syns. *L. major* and *L. pilosus*).—This also is yellow. It blooms in June, and grows about 18 ins. high.

LOTZEA.—Now included in the genus ASPLENIUM, for which see *FERNS AND FERN GARDENING*.

LOVAGE.—See *LEVISTICUM* and *LIGUSTICUM*.

LOVE APPLE (*Lycopersicum esculentum*).—See *LYCOPERSICUM*.

LOVE GRASS.—See *ERAGROSTIS* and *ORNAMENTAL GRASSES*.

LOVE-IN-A-MIST (*Nigella*. Nat. Ord. Ranunculaceæ).—Most of the hardy annual Nigellas make bushy plants, with their elegant foliage and interesting and showy flowers, if raised by sowing in the open in autumn, while later bloom can be secured by sowing seeds where the plants are to bloom any time in March or April. The plants have a strong objection to being transplanted, and instead of attempting this they should merely be thinned to a foot or more apart.

What to Grow.—*Nigella damascena*).—The popular DEVIL-IN-A-MIST, LOVE-IN-A-MIST, JACK-IN THE-GREEN, and JACK-IN-PRISON,

so called because its blue flowers have green veiling. There is a white form, and the variety *Miss Jekyll* has large, double, deep blue flowers, and is fine for cutting. All flower from June onwards and average 1 ft. high.

N. hispanica produces blue flowers in the summer and autumn, and is 1½ ft. high; the variety *alba* has white flowers and brown anthers.

N. orientalis.—A species with yellow and red flowers, of no special merit as a garden plant, but a free bloomer from July onwards. Height, 1½ ft.

N. sativa[1] produces blue flowers all the summer. Its height is 1½ ft.

C. H. C.

LOVE LIES BLEEDING (*Amarantus*. Nat. Ord. Amarantaceæ).—The several members of the genus Amarantus referred to here are really half-hardy annuals, although, because of the hardiness of certain species in the warmer parts of the country, they are sometimes described as hardy. They are mostly of vigorous growth, and some are attractive by reason of their heavy, tasselled, drooping, and branched spikes of closely packed tiny flowers, while others have brilliant-hued foliage. All are strikingly effective in borders, and in conjunction with Palms and giant Reeds they produce a sub-tropical effect. They are best raised in gentle heat in March, potted separately at an early date in sandy loam, and kept under glass until May, when they must be gradually hardened off, preparatory to being planted in the open in June. A sunny, sheltered position is essential to success. Given rich soil, sunshine, and suitable supports, they range from 1½–4 ft. in height. The following are the principal species and varieties for garden use:—

Amarantus caudatus (Syns. *A. gracilis* and *A. pendulus*).—The popular LOVE LIES BLEEDING, with velvety-purple flowers from July onwards. It grows about 2½ ft. high.

A. gangeticus (Syns. *A. japonicus* and *A. melancholicus*).—A sort bearing both crimson flowers and crimson foliage. It blooms freely from July onwards, and averages 1½ ft. in height.

A. Henderi.—A hybrid with carmine, orange, and olive-coloured leaves. It blooms from August onwards, and averages 1 yd. in height.

A. hypochondriacus (Syns. *A. bicolor* and *A. macrostachyus*).—This sort, the well-known PRINCE'S FEATHER, bears deep crimson flowers and leaves with purple beneath; the variety *ruber* has crimson flowers and green and purple foliage. Both bloom freely from July onwards and average about 3½ ft. high.

A. paniculatus (Syns. *A. chlorostachys*, *A. cruentus* (Linn.), *A. incarnatus*, *A. sanguineus* (Linn.), *A. speciosus*, and *A. spicatus*).—A sort bearing red-tinted leaves and producing crimson-purple flowers freely from July onwards, on plants 1 yd. high.

A. salicifolius.—A species bearing bronze or orange leaves with insignificant flowers. The variety *Princess of Wales*, with orange yellow and green leaves, was once very popular. Both sorts grow about 1 yd. high.

A. tricolor.—This has purple, red, green, or yellow leaves. The variety *splendens* has crimson, scarlet, yellow, and green-coloured foliage. The flowers are insignificant. Both sorts grow about 3 ft. high. *A. tricolor* is sometimes

[1] The BLACK CUMIN.—EDITOR.

accorded specific rank, but it is probably only a form of *A. gangeticus*.—C. H. C.

NEW VARIETY.

Amarantus Dr Martin.—This has bright red upper leaves, bronzy lower leaves, and bright red stalks.

LOW BIRCH (*Betula pumila*).—See *TREES*.

LOW BLACKBERRY (*Rubus canadensis*).—See *SHRUBS*.

LOW BRAMBLE (*Rubus canadensis*). See *SHRUBS*.

LOW BUSH BLACKBERRY or **LOW BUSH BRAMBLE** (*Rubus trivialis*). See *SHRUBS*.

LOWBERRY.—See *BRAMBLES AND BERRIES*.

LOWER FUNGI.—See note on PHYCOMYCETES in *FUNGOUS DISEASES*.

LOWIARA.—See *ORCHIDS*.

LOXOSCAPHE.—Now included in the genus DAVALLIA, for which see *FERNS AND FERN GARDENING*.

LUBINIA.—Now included in the genus *LYSIMACHIA*.

LUCERNE (*Medicago sativa*).—See *MEDICAGO*.

LUCOMBE OAK (*Quercus lucombeana*).—See *TREES*.

LUDWIGIA (FALSE LOOSESTRIFE. Nat. Ord. Onagraceæ).—This genus, of which only one species (*L. palustris*) figures in the *Kew Hand-list of Herbaceous Plants*, is not of much value for the water garden or moist mixed border. It is named here to draw attention to the fact that it is not the true Loosestrife, though often at first glance one might take it to be. Examination of its flowers shows, however, that it belongs to a different and distinct natural order, namely, to that including the *EVENING PRIMROSE*, on which plant we devote a separate article. It may be regarded more as a moisture-loving, hardy, creeping, herbaceous biennial than as a true hardy aquatic, and bears yellow flowers in July.

LUNARIA.—See *HONESTY*.

LUNGWORT.—See *PULMONARIA*.

LUPINE (*Lupinus*. Nat. Ord. Leguminosæ):—**Annual Sorts.**—These are scarcely less stately than the perennial species, and raisers have done much good work among them in recent years, thereby enriching our gardens considerably. The tall spikes of flowers, borne above elegant leafage, swaying gently in the summer breeze, at once suggest the peace and homeliness of a quiet country garden.

CULTURE OF ANNUALS.—Sow seeds in autumn or early spring where the plants are to flower; or in pots; pricking off and planting out at a very early stage. Choose a sunny site, and soil that contains a fair supply of lime. Some fine garden plants are listed under the name of *Lupinus hybridus*. Below is a selection of the best species to grow:—

Lupinus Cruckshanksii.—This fine plant produces blue and white flowers during the summer; possibly it is a variety of *L. mutabilis*. Height, 4 ft.

L. densiflorus (Syn. *L. Menziesii*).—A white and pink, summer and autumn flowering sort.[1] Height, 1 ft.

L. Hartwegii.—A pale blue, summer blooming sort. Height, 2½ ft.

L. luteus.—A yellow, summer flowering sort. Height, 2 ft.

L. Menziesii.—Syn. *L. densiflorus*, which see.

L. mutabilis.—A white and blue, summer flowering sort. Height, 3–5 ft.

L. nanus.—A lilac and blue, summer blooming species. Height, 1–2 ft.

[1] Often known as SHEEP POISON.—EDITOR.

LUPINE : Hardy Perennial Species. These include some of the finest of all hardy border flowers. Their free-flowering nature is well known, and their lovely spikes are a sight not to be missed. The Tree Lupines (*Lupinus arboreus*) are a different class of plant from the others ; these, as their name implies, are more like small trees than herbaceous plants when they are several years old.

CULTURE.—All the perennial Lupines thrive in any good, rich, well-drained soil in a sunny site, or indeed in a lightly shaded spot. The Tree variety is renowned for its power to bloom and grow freely on very poor land, though, needless to say, it does best if it has some food in the soil. Planting should be done any time from November to late February, taking great care that the long, thick, fleshy roots are not doubled up, but go down straight into the soil. Early staking is essential or the plants may be damaged. The dead spikes should be removed as soon as possible if further flowers are wanted, and the plants given suitable phosphatic or potassic liquid manure. Fertilisers containing nitrogen should not be used, as the plants belong to the Order Leguminosæ, and are thus able to get all they want from the atmosphere.

Propagation is simple if seed is sown, but difficult if division of the rootstock is attempted. Seed, which is easy to sow, and which usually germinates very freely, can be sown any time out of doors, or in a frame, from March to the end of August, and the seedlings pricked off and planted out in the usual way.

USES.—The Lupine, having the power of obtaining nitrogen from the air, is much used as a green manuring crop. Some varieties are used as cattle food. In the garden it finds its chief place in the herbaceous border, but may also be used in the wild garden or along the margin of the shrubbery. The spikes, which are often of considerable length, can be used for cutting, though they are not so good for this purpose as are other flowers.

What to Grow.—There are a large number of sorts to choose from. We recommend the following :—

Lupinus arboreus.—This flowers freely in June, often giving more bloom in the autumn, and ranges from 3–5 ft. in height. There are many good named sorts. *Daisy Hill* is pale blue, and *Snow Queen* is white. A yellow sort, *Luteus*, is also useful. Propagate by cuttings or seeds.

L. aridus.—An autumn flowering sort bearing purple and blue flowers. Height, 12 ins.

L. Chamissonis.—A useful blue, September blooming Lupine about 3 ft. high.

L. leucophyllus.—A species which is almost perpetual blooming, as it often opens in late May and continues until the end of the autumn. Its flowers are pink, and its height varies from 2–5 ft.

L. littoralis.—This succeeds in seaside gardens. It blooms all the summer, and its flowers are purple or purple-blue. Height, about 1 ft.

L. nootkatensis.—A blue and white species, blooming in May and June. Height, 1 ft.

L. polyphyllus.—This is the border Lupine of which we are all so fond. It will start flowering in early seasons about 15th May, but is at its best early in June, and will flower again, if well treated, in the autumn. Its height varies from 2½–5½ ft. There are numerous named varieties : *Albus* is white ; *Caeruleus*[1]

[1] Popularly known as the BLUE LUPINE.—EDITOR.

is blue; *Foxii* is blue and white; *Giant Purple* is purple, as its name implies; *Moerheimi* is pink, and probably the most attractive of all; *Purple King* is best described as a rich purple, and *Purple Queen* is similar; *Roseus*[1] is an attractive rose-pink; *Somerset* is a fine yellow, and *Sulphur Queen* is yellow.

There are many more species and varieties of Lupines which are very attractive. The enthusiast should visit a good botanical garden in June and September if he wants to fill his notebook with their names.

LUPINUS.—See *LUPINE.*

LUTEOLA.—Now included in the genus *RESEDA.*
